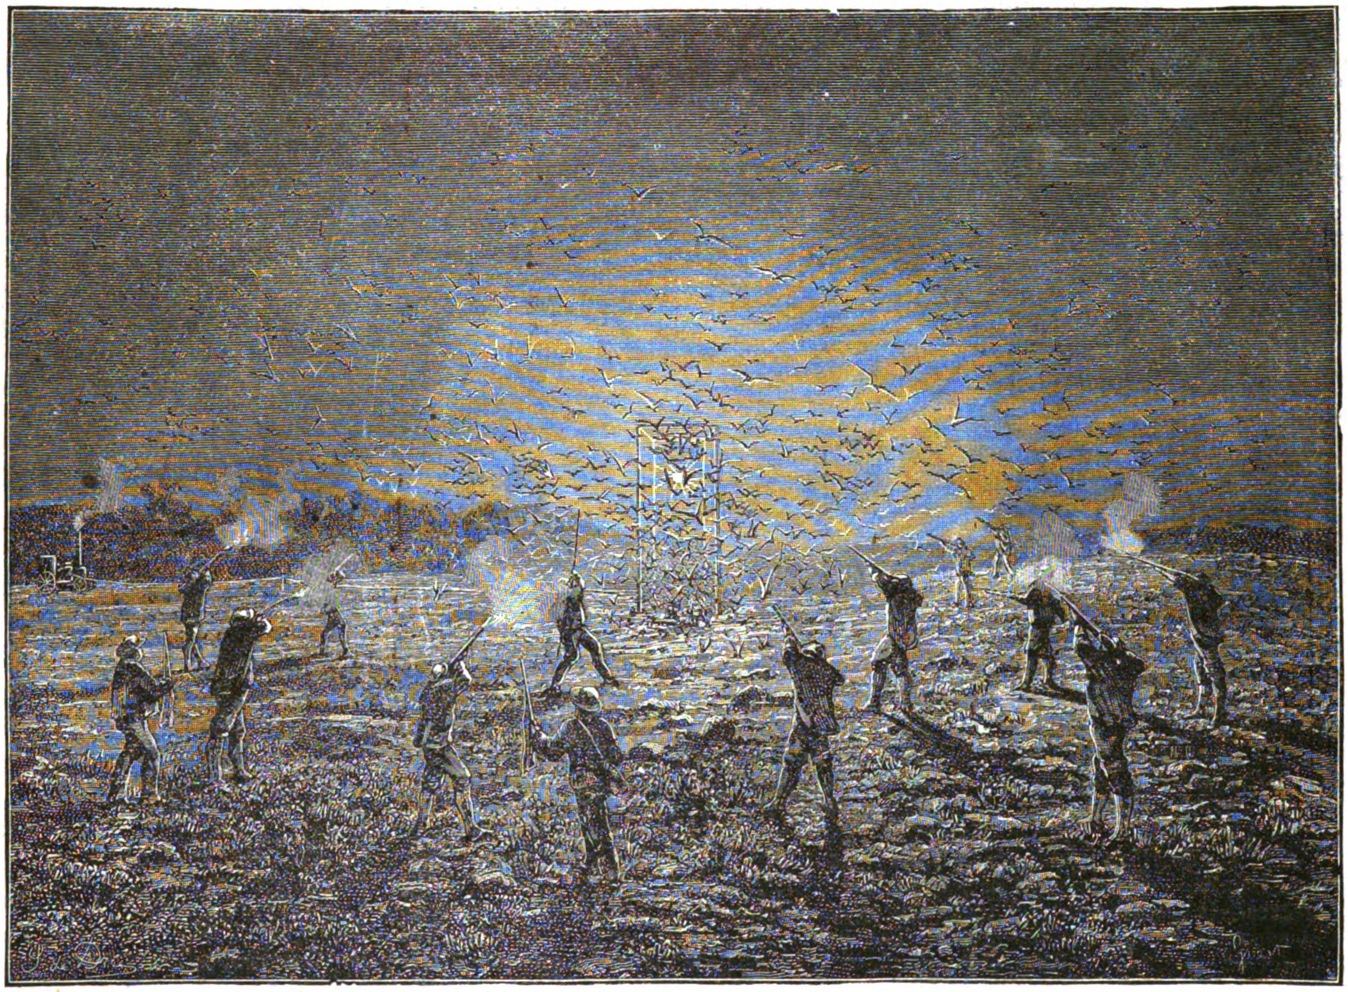
ELECTRIC LIGHTING AND SHOOTING.

READERS of manuals of shooting, must well remember the scenes of night shooting, or the midnight spearing of salmon, as portrayed in Scott's Rob Roy. Shooting manuals, of course, give sapient advices as to the dangers that men, unprovided with flannels, and on the shady side of forty, must necessarily encounter. We are not partisans of the unnecessary slaughter of the beautiful tenants of the air, exterminating the comparatively small number of the denizens of air that still remain.

These electric shooting parties, have excited great indignation, even in England, where young ladies find a pleasure in hunting the timid hare to death, and bagging the fox, which, (vermin though he be,) seems to have been created for some purpose unknown to us.

Electricity need not be made an adjunct to so-called sport.



SPORTING BY ELECTRIC LIGHT.

of the cruel hunting of a few of the declassés of God's creatures; and, although, we have before our eyes, a very striking picture of electricity applied to what is the French idea of sport—a *battue*, we are confidently of the opinion, that the good sense of our people, in default of Mr. Bergh's exertions, will never require the application of electricity in

THE PROSCH TELEGRAPH KEY.

TELEGRAPH keys, distinguished from the form so long in use by new and obviously advantageous features, have rapidly multiplied within the last few years. A light, elastic lever replaces the old, heavy, rigid lever. Solid trunnions replace shaky trunnions, or a peculiar joint

ELECTRIC LIGHTING.

THE MISTAKEN IDEAL OF ARTIFICIAL LIGHT IMPROVERS.

BY DR. W. H. BIRCHMORE.

IT seems strange to one, who has made it his business to study and collate the results of other men's labor and experience, to see how, from time to time, some one will point the way by which a much-desired result is to be arrived at, or a given improvement in a manufactured article made, and yet how steadfastly the very men who point the way will persistently follow some other path, which they in many instances complacently warn their fellow-workers is not the right one. The last instance of this sort of thing which has passed under my notice is contained in the work entitled, "Industrial Photometry," by Palaz, p. 17:

"Finally O. E. Meyer (*Monatber. der Berliner Akad.*, 1880,) obtained the following values, taking the rays emitted by a gas flame as a standard, and making the intensities corresponding to the *D*-line unity.

Rays of the Spectrum.	*B* (Orange.)	*D* (Yellow.)	*E* (Green.)	*G* (Violet.)
Petroleum lamp.......(1)	0.66	1.00	1.40	1.00
Sunlight, direct.......(2)	4.07	1.00	0.48	0.15
Sunlight, diffused.....(3)	1.25	1.00	0.50	0.41
Voltaic arc.......... .(4)	1.10	1.00	0.40	0.10
Incandescent lamp....(5)	0.80	1.00	1.40	1.10

The above results are sufficient to allow of the classification of sources of light according to the nature of the light which they emit."

The above quoted passage gives one of the most inter-

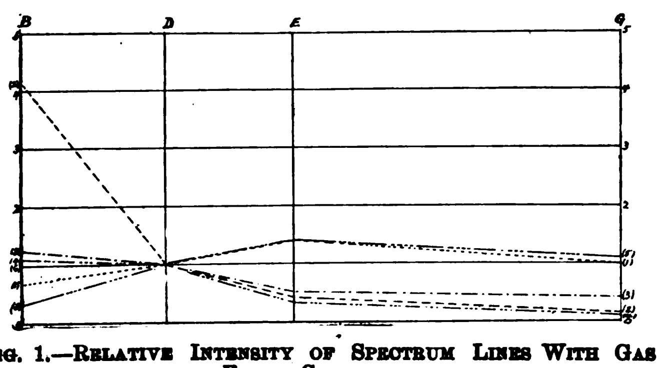

FIG. 1.—RELATIVE INTENSITY OF SPECTRUM LINES WITH GAS FLAME STANDARD.

esting contributions of the book in regard to the matter at issue, and is worthy of an extended discussion in a way which Palaz did not choose to use the figures therein contained. The process by which the figures were reached seems to have been much as follows: The rays in the neighborhood of the *D*-line were rendered equal by the arrangement of the sources of emission, and then the relative amount of the rays at each of the other lines measured, using the amount emitted by the gas flame as unity. There are at least a half-dozen ways in which this can be done, and the one employed is indifferent, in the result, so long as the work is well done.

In discussing these figures it must be remembered, that no matter how accurate they were for the time and place of making, they cannot be verified at will, because the light of one day is hard to adjust with the light of another; but they may justly be taken as representing exactly the conditions of the experiments of which they are the record. It is then only needful to put them into

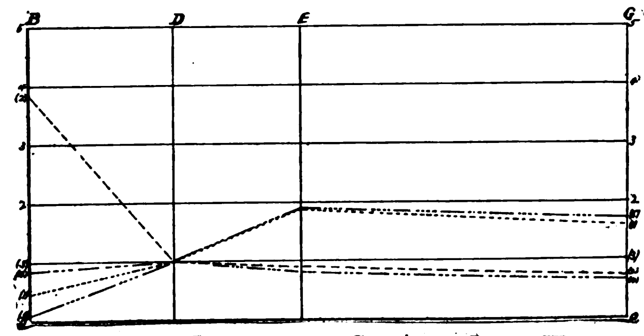

FIG. 2.—RELATIVE INTENSITY OF SPECTRUM LINES WITH SUNLIGHT STANDARD.

a shape where their significance becomes obvious. This I have done by constructing the accompanying diagrams.

In Fig. 1, the gas flame light is used as the standard; in the Fig. 2, the "Diffused Sunlight" (daylight), is employed in the same capacity. The lines *b*, *d*, *e*, and *g*, are spaced as in the Sun spectrum. By examining these diagrams it appears that at the time of the experiments the direct sunlight (2) contained rather more than fourteen times as much red for the same amount of yellow as the incandescent lamp light had; (5) is the curve of the incandescent lamp light; (3) represents the curve of "daylight," and (4) that of the arc; (1) is that of the petroleum lamp. (6) represents the curve of the gas flame, and as it is the standard it is represented by a straight line.

Examination of these curves in Fig. 1, makes it clear that with the standard chosen, the rest of the lights divide into two parts: on the one hand, the petroleum and the incandescent electric lamp, containing a larger proportion of blue, green and violet; and on the other the arc lamp, and both sunlight and daylight, which contains less of these rays than does the incandescent flame. This excess of violet light plays a very important part in the "eye strain" to which so much of the "neuralgia" of women, and the headache and worry of men are due.

Fig. 2 emphasizes the same fact. It is clear that every one of the sources of light examined contains more of the blue, green and violet than does the diffused sunlight, except the "arc" light; which comes nearer the proportion of direct sunlight. It is also made clear that even diffused daylight contains more than eight times as much red for the same amount of yellow, as does the incandescent electric lamp, that is, the carbon filament,

These diagrams have a direct bearing on the phenomena known as the maximum stimulus, and also offer an explanation of its raison d'être. Although the definition of the phenomenon is well known, the phenomenon itself has always been an indeterminate quantity in all photometric experiments, and a very serious difficulty in the solution of illumination problems. In order that my definition may not be caviled at, I quote that of Palaz: "The maximum stimulus is the superior limit, above which an increase in the intensity of the stimulus produces no increase in the intensity of the sensation." My object in this discussion is to make clear, if I can, how a purely physiological factor is at the bottom of the present difficulty with our lamps and to show that it is not in the dicta of a Bunsen photometer that we must find our standards but in the brightness of certain colors, and in the "spectra of reflection."

A series of experiments covering a number of individuals makes it apparent that this maximum stimulus varies not with the amount of light at large, but with the amount of light of particular kinds. If an apparatus be used, constructed for the purpose, including a differential photometer of some sort, and a pupilometer, it can be shown that the number of rays of a monochromatie light in the neighborhood of B-line required to produce a given contraction of the pupil is twenty-five times as great as the amount required from the neighborhood of the G-line to produce the same contraction. It thus becomes a matter of the first importance to determine the relative proportion of the various kinds of light in the rays sent out by the illuminants which are the subject of our inquiry.

Expressed in percentages the relative proportions of the various rays in these illuminants, using these same figures of Meyer, appear as follows:

Percentage Composition.

Ray of the Spectrum.	B (Orange.)	D (Yellow.)	E (Green.)	G (Violet.)
Petroleum lamp........(1)	16.2	24.6	34.5	24.6
Sunlight, direct........(2)	72.0	17.7	7.6	2.7
Sunlight, diffused......(3)	39.5	31.6	15.9	13.0
Voltaic arc............(4)	42.3	33.5	15.3	8.9
Incandescent lamp.....(5)	8.0	26.3	36.8	28.9

Bearing in mind that for thousands of years the pupil has been protecting the eye from direct sunlight, and that it has only recently been called upon to protect it against violet light, the above figures are particularly significant, as they show that the pupil would contract nearly or quite as fast for the B-line rays of the "direct sunlight" as it would for the G-line rays. $72.0 \div 2.7 = 26.6$. This shows that on a very bright day, sunshine, the size of the pupil, and consequently of the light pencil, *i. e.*, the total light received by the eye, is limited by the red or orange rays. In other words, on a bright day out of doors, we do our "seeing" with the impressions produced by red and yellow rays.

Studies made on the "Plains," in Algiers, and in the Northern part of Russia appear to indicate that the various observers found the light of a sunshine-day of about the same centesimal composition everywhere. It is a rather difficult matter to compare and adjust the results, for among so many different methods and observers there were of necessity differences in instruments, instrumentation and in personal equation of which no one holds the clue; still it seems that under the same condition of the "rain band" the amount of light of the various kinds is much the same all over the world, unless it is varied by some special local cause; for example, in New York there is a strictly local rain band nearly all the time.

If the direct sunlight, of Meyer, is translated to mean the light of a bright, dry day, and it agrees surprisingly well with all the data of such days, we may with equal justice translate his diffused daylight to mean the daylight of a cloudy day; on this basis also some most astonishing coincidences with the results of the labor of others are to be obtained.

In the first place it is seen that the opinion of landscape painters that a day of this sort should be called a gray day is very well founded; the tints of all sorts have a tone that it is hard to account for, and objects appear dim. These facts are due to two unlike causes, first to the color of the incident light, and the spectra of reflection which it produces; and second to the fact that the eye refuses the light, and makes small use of what there is of it.

Pupil measures show that if monochromatic orange light is dimmed the pupil expands at the same rate, admitting the same amount of light at all times; they also show that if the light of a very bright day is dimmed by decreasing the aperture through which it comes, the results on the pupil are absolutely identical; therefore, if a gray day were simply a day of less light, the pupil would expand, the aperture through which the light reached the eye would increase in area, and as the same amount of light would be admitted, the sensation of light and shade, and the impressions of color, would be identically the same at all times. This is not at all what happens; the pupil is usually smaller on a gray day than it is on a bright one, thus showing that the amount of light which enters the eye is actually less. Less not only as to the rays which the clouds shut out; but also by a larger number which the eye mechanism itself excludes, for some reason which is an automatic stimulus to such exclusion.

The statements of Meyer give the reason for such exclusion, and give it plainly; it is the influence of the G-line rays; the eye finds itself overpowered by these rays and shuts its diaphragm and excludes the total light until the amount of the G-line rays admitted is made equal to the amount of the same rays admitted in the sunshine. Referring now to the table of the percentage composition of the lights, we find that for every hundred violet rays admitted, the eye admits as follows:

Ray of the Spectrum.	B	D	E	G	Total.
Sunlight, direct (2)..........	2664	656	281	100	3701
Sunlight, diffused (3)........	731	585	294	100	1710

Consequently the absolute number of rays of light which enter the pupil on a gray day is less than half of the number of those which enter on a bright one. This is on the assumption that the owner of the eye is simply looking "into the void of heaven." If he is trying to do anything else, except read a carefully selected ink imprinted on a carefully selected paper, the eye will not even receive this half of the rays to which it is accustomed, for while the diffused light controls the size of the pupil to the greatest degree, the light which is reflected from the object at which the owner looks determines the spectrum of reflection, and therefore those sensations of contrast by which form and color are made evident to the mind. Applying the same method to the "incandescent electric lamp" the following result is reached:

Rays of the Spectrum.	B	D	E	G	Total.
Incandescent lamp (5)......	21	92	137	100	340
Petroleum light (1)..........	85	100	138	100	423

This shows that for the same number of violet rays the sun-light has 10 times as many luminous rays as the incandescent electric light, and nearly 125 times as many red; yet the aperture of the pupil will be the same size for the 340 rays of the incandescent lamp as for the 3701 of the sun-light.

This shows that both of these lights are rich in violet

rays; gas light which used to be rich in red rays is now losing them in the race for white light and has become as rich in violet as the petroleum, although still richer in red; and therefore in both the incandescent lamp, and in petroleum lamps of all sorts, the total number of light rays that can be utilized is very small, simply because they are already too rich in violet light.

These facts are still more complicated, and the fitness of the present ideal of the lamp improvers is still further impeached by the fact that lamps are not intended to be looked at, but to see things by; that is to say, to have their light absorbed and reflected in various ways by the objects about them, and thus to make the eye sensible to their presence by sensations of form and color. Without going into the details of the spectra of reflection, it may be well to state that more than one-half of all the objects in this world are made visible to us by the reflection from their surfaces of rays between the *B*-line and the *D*. Consequently the objects seen by the incandescent lamp are objects seen on a very gray day indeed.

All this has nothing to do with the candle power of the lights as measured on a Bunsen photometer, or with any apparatus which obtains a comparison in this way, but depends on the physical relation between the stimulus and the physiological reaction which it produces.

There is no announcement of new facts in all this; the men who are studying the act of vision and its relation to the improvement of artificial lighting have been pointing to these relations between light and seeing since 1882, and it does seem hard that those who write books and give the impulse to so much of human labor will not attend to them. Even Palaz, who of all men ought to know better, sets up the light of the glow worm as the ideal to which the lamp men should work; yet if he had stopped to think, he would have remembered that even if he could make a light of any desired intensity in this way, the eyes of the largest part of mankind would quickly decide the question and declare that after all it was only a makeshift for the sunshine and a poor makeshift at that.

The true ideal of the lamp men is not the glow worm but the sunshine, and if they expect to get sunshine without heat, let them; but it is doubtful if the world would agree that it was a good thing if they did; they would find it only moonshine after all their trouble. Just as long as 75 per cent. of the reflected visual intensity of the sunlight is longer in its waves than *D*, and it will be so probably for some time yet, it would be better policy on the part of those interested in improving lamps to adopt it as their ideal, rather than try to attain one to which they must educate the light sense of mankind: a task from which the most enthusiastic of the believers in the public school system would shrink, if he were able to understand the meaning of his ambition.

PRICE RESTRICTIONS AT LANSDOWNE, PA.

The Lansdowne electric light ordinance contains a number of restrictive provisions in regard to price, not only for street lighting, but also for private dwellings. Where 100 lamps or over are installed, the price is not to exceed $2.50 per annum; where less than 15 lamps are used the price is not to exceed $3.50 per lamp. If the householder prefers to pay for actual consumption, the price is not to exceed three-quarters of a cent per lamp per hour. Twenty-five candle power incandescent street lamps are to be furnished for $12 per year each.

THE BRAINERD MUNICIPAL PLANT SOLD.

The vote on the proposition for the city of Brainerd, Minn., to sell its electric light plant to C. N. Parker, of that city, and E. C. and P. A. Gibson, of New York, resulted in a vote of 723 in favor of the proposition to 142 against. Ten thousand dollars will be expended for improvements on the plant at once.

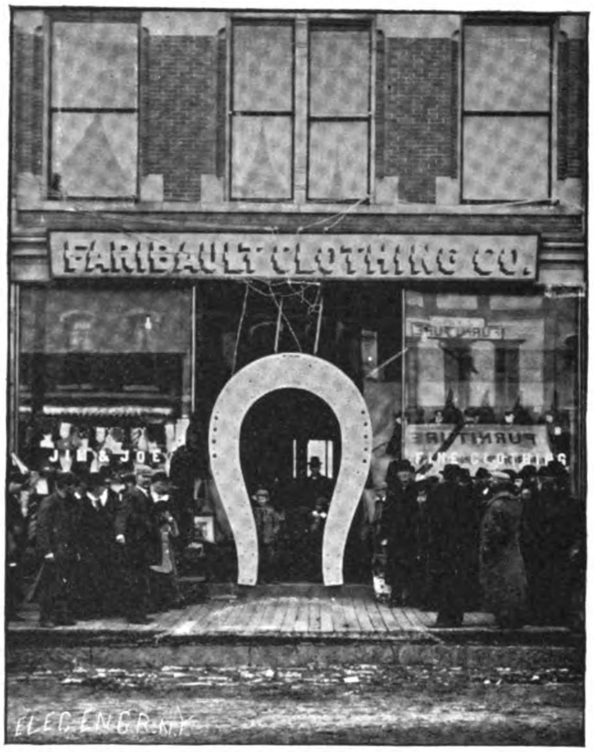
SOME FEATURES IN THE STANDARD SOCKET DISCUSSION.

BY GEORGE T. HEWES,

Gen. Man. Faribault, Minn. Consol. Gas and Elec. Co.

FOR the same reason that individual central stations adhere to some particular style of socket for a "standard" in their work, it is as quite essential, that a "standard" socket for universal use be procured. Without entering into a discussion of the special advantage or disadvantage of the many sockets on the market, the writer desires to advocate the Thomson-Houston socket as the most advantageous in its simplicity for connecting up, its immunity from short circuit, etc.; while for temporary illumination purposes a kindred substitute can be easily and cheaply constructed.

Recently, upon short notice, the writer had occasion to



A SPECIAL STREET ILLUMINATION SIGN BUILT FOR USE AT FARIBAULT, MINN.

devise a street illumination for one thousand lamps, extending along the side of the public streets in Faribault. He procured one hundred strips of elm, 2½ inches wide, ½ inch thick and dressed on both sides. On each side was stapled one length of bare copper wire, No. 10 B. & S., and ten machine screws, connected with the underneath wire, projected through the wood the required distance from the upper wire, thereby improvising a perfect keyless Thomson-Houston socket. These strips can at any future time be bent in many symmetrical shapes by first immersing in water for a few hours. Imagine, the cheap advertising sign which can thus be constructed! Not one of the thousand lamps failed to glow; nor were they in the least affected by an unexpected rain storm.

The cost of one thousand sockets would have been in the neighborhood of $150, without estimating the expense of labor for connecting; and the additional expense of insulated wire would have made the expense prohibitory. Yet, the insulation between the bare wires was perfect for all practical purposes, and the expense for the screws was

but $5.00. The illustration of the horseshoe shows what can be done with one hundred lamps at an expense of fifty cents for sockets.

What other socket can be so cheaply imitated with the same satisfactory results? Is it not time the central station manager first looked to his own interests, and did not allow manufacturers to settle the question of "standardizing" a socket to his disadvantage?

THE BENNETT BISULPHIDE OF CARBON ENGINE.

BY LUCIUS T. STANLEY.

MANY have been the attempts to employ as the working fluid in the steam engine vapors other than steam, derived from liquids having vapors of higher expansive force at a given temperature. Among these, bisulphide of carbon and ammonia have been favorites among inventors, and the most recent attempt in this field is the engine arrangement devised by Mr. J. R. Bennett, of Philadelphia.

It may be remarked, that in the many attempts that have in the past been made in this direction, two radical conditions—either or both conducive to failure—have presented themselves, and these are:

First, inability to maintain a constant pressure of the chemical vapor; and, second, inability to properly lubricate the cylinder and its working parts against the high temperature incidentally developed. This second condition has probably been generally misunderstood. Because the working parts of the engine which were in direct contact with the vapor soon became roughened and furrowed, it was believed that the vapor had a destructive effect upon the metal. It is claimed that Mr. Bennett's experiments have not only disproved this theory, but have demonstrated that bi-sulphide of carbon at least is a cleanser and preservative of iron and steel. There is reason for belief that these adverse conditions above noted have been overcome in the system now under consideration.

In the accompanying diagram the salient features only of the system are shown; details of the water supply and of the device for primarily charging the generator, etc., being omitted in order to avoid confusion.

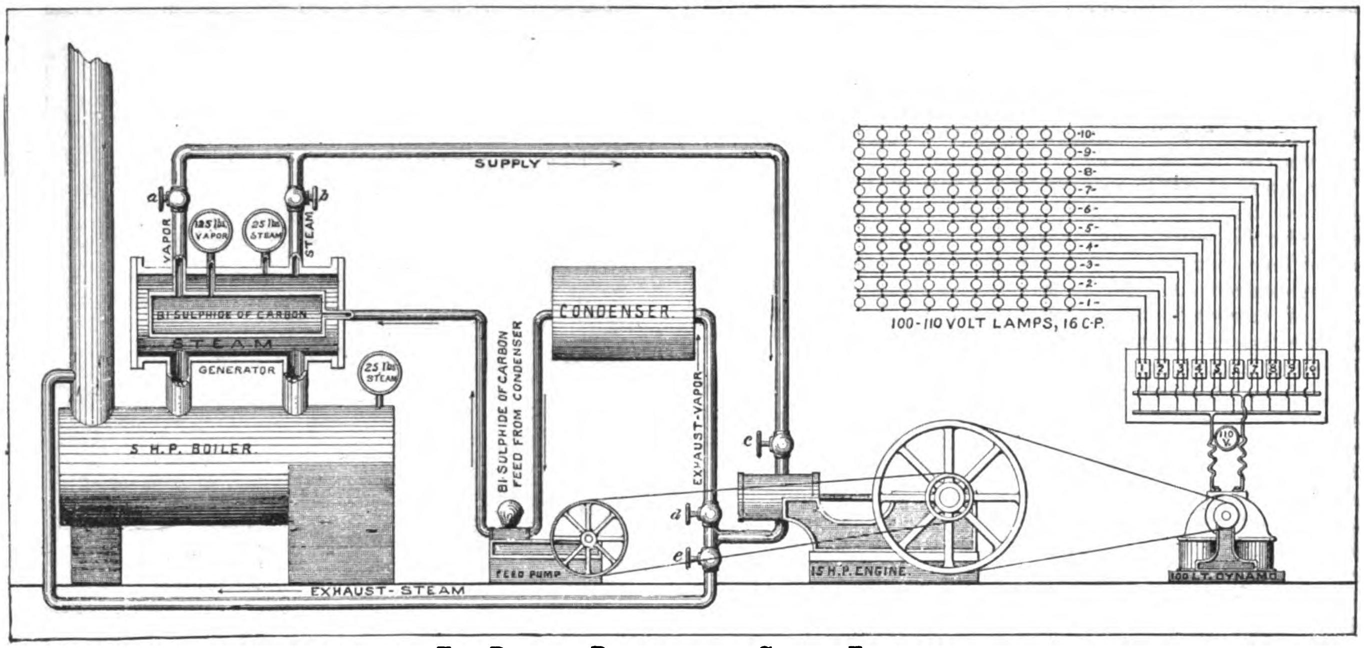
For the purpose of comparing the power derived from steam direct, and that derived from chemical vapor generated by the same steam, both the steam boiler and the vapor generator are connected to the engine by a common supply pipe through valves *a* and *b* which are conveniently arranged for alternate connection to supply. In practice there would be only the connection between the generator and the engine, the steam boiler acting solely as a heater.

The boiler is of the common tubular horizontal type, upon the top of which is set the "generator," composed of a steam drum within which is the cylindrical receptacle for the bi-sulphide. Supply connections to the engine are made in the conventional manner. The vapor exhausts into the condenser, which is the common arrangement of a worm or coil surrounded by a water jacket. In this plant the condensed exhaust is pumped from the condenser into the generator, but in practice, it will be trapped from the condenser into the generator. The steam exhausts directly into the chimney.

The engine is an Armington & Sims, of 15 H. P. The dynamo is compound wound and of 100 lights capacity at 110 volts. The lamps are of 16 C. P., 100 in number and arranged in 10 branch circuits of 10 lamps each; each branch being controlled by an individual switch.

When the steam gauge showed a pressure of 25 lbs., valves *b*, *c* and *e* were opened and the engine started. In a short time, the voltmeter showing a pressure of 110 volts, switch No. 1 was closed and branch circuit No. 1 was lighted, giving full glow. Throwing in circuit No. 2 caused both circuits to glow at about one half power and there was a corresponding drop in voltage, thus demonstrating that 25 lbs. of direct steam was capable of performing work to the extent of about 1 H. P. only. In the meantime the bi-sulphide of carbon, with which the generator had been primarily charged, had been heating, and the pointer of the vapor gauge began to move gradually until it finally registered 125 lbs., when valves *b* and *e* were closed, valves *a*, *c* and *d* opened and the feed pumps started. At once the engine responded to the increased pressure (the transformation from steam to vapor taking less than one minute) by increasing its speed, and one after the other the branch circuits were thrown in until six were glowing with full power, the voltmeter steadily indicating 110 volts pressure. By throwing in the seventh branch circuit, the glow was slightly dimmed and there was a slight drop in voltage.

Upon being asked if this was the limit to the power to be derived from the 125 lbs. pressure, Mr. Bennett explained



THE BENNETT BISULPHIDE OF CARBON ENGINE.

that, the engine being simply bolted to the floor, and having no solid foundation, it was the limit of safe running for any prolonged period. However, in order to show that it was not the limit of power, he opened the throttle *d* a little more, when two more branch circuits, making eight in all, were thrown in, and the 80 lamps glowed with full power, the voltmeter holding steadily at 110 volts. This was for a couple of minutes only, as the engine and room were in a tremor, and the supply was again throttled until the six branch circuits only were in circuit. Here it was held.

The writer remained for perhaps an hour longer, and during that period the pointer of the vapor gauge remained at 125 lbs. as if it were fixed there; the voltage remained steadfast at 110, the 60 lamps glowing at full power. There was no undue heating of the cylinder or its working parts, and during this entire period the steam gauge recorded a steady pressure of 25 lbs.

Apparently there was nothing to prevent an indefinite continuance of these conditions, so long as coal was kept burning in the fire box.

The plan for maintaining constant pressure at the generator gauge is based upon the principle of the circulating steam or hot water heater. After heating the water to the point of evaporation for a desired pressure, all heat energy beyond that necessary for this purpose is carried along with the steam, or with the water as it may be, as heat instead of being used to increase the pressure, heat alone being needed in the outside shell of the generator.

The lubricating medium for the cylinder and its parts is a compound; the basic ingredient being a substance that has no affinity for any of the chemicals that may be used for this purpose, and which, moreover, is practically unchanged by any degree of heat possible to be generated in the cylinder. Its application is novel and apparently efficient, and it probably has a value in direct steam practice at extreme pressures.

This system is being introduced by The Giant Power Company, composed of business men of the highest standing in Philadelphia. This company now has in hand the erection of a plant of 100 H. P. capacity which is expected to be ready for inspection early during the present year.

The plant above described is at 145 North 7th street, Philadelphia.

MUNICIPAL SOCIALISM AT DETROIT, MICH.

The proposal that the public lighting plant shall embark in the business of furnishing light to private consumers as well as to the public buildings is one, says the *Detroit Free Press*, that calls for serious consideration before it is adopted. It is quite possible that under judicious management, if we could always rely on having such, light could be supplied at a lower rate than private concerns are charging; but it does not by any means follow that for this reason it would be wise to embark in such an enterprise. There are other things to be taken into consideration and chief among these is the commitment of the city to the socialism involved.

For if it is an argument in support of furnishing light to the private consumer from a public plant, that the latter can do it more cheaply than private concerns can, the argument is equally strong in regard to many articles of general consumption. It is much stronger indeed in respect to other things than it is in respect to electric light. That commodity, though now used to a considerable extent in the city, is largely a luxury. It is not in general use and would not be even at the price for which it could be furnished by the public lighting plant. The saving, if any, would benefit a comparatively small class and that composed of those who do not stand greatly in need of public assistance.

The *Free Press* then instances bread and shoes as things of far more vital interest to a large part of the public than electric light, and adds:—In point of fact, for reasons already given, the making of bread and shoes for the multitude in a public plant could be justified upon grounds which are wholly wanting in the electric lighting argument. In considering this matter we have for the argument's sake left wholly out of consideration the question whether the people would directly benefit for any great length of time. The public lighting which seems now so successful is, it should be remembered, an experiment. If it can be kept perfectly free from politics and managed with sole reference to furnishing the best possible light for the least money, it will continue to be a success. But what assurance have the people that it will so continue? The tendency, unfortunately, is away from that condition of things. The people do not need to be reminded that there has been for many months a drift toward the rendering of all commissions and departments subservient to the executive power and that an open effort has been made in more than one case to use that subserviency for personal and political aggrandizement. How much of that can the public lighting system or any other department of municipal business stand and continue to render good economical service? The question is not an easy one to answer; but it is important enough to suggest the propriety of going slow in regard to any extension of the principle involved in the public lighting system beyond the field of public service. As *The Free Press* has always insisted, it is an experiment to the making of which we were driven by an unhallowed "combine" among the electrical companies of the country; and time only can show whether it is on the whole a wise thing to do. Let us not complicate matters by overloading the experiment unless we are prepared to go the extreme length of municipal socialism hinted at in the illustrations we have offered.

WHERE THE INCANDESCENT LAMP IS UNKNOWN.

The most deplorable feature about the calamity at the mining town of Dayton, Tenn., is the fact, comments the *Pittsburgh Chronicle Telegraph*, that sixteen men lost their lives needlessly. They used the dangerous open lamps in their work, regardless of the record of death from such carelessness with which the history of coal mining is strewn. As long ago as 1815 Sir Humphrey Davy invented a lamp to prevent accidents in coal mines, founded on the principle that flame, in passing through iron wire meshes, loses so much of its heat as to leave it incapable of igniting inflammable gases. Yet at this late day there are mines employing scores of men, in which naked lights are used, ready to ignite explosive gases at any moment, and send the workmen into eternity. The company which operates the Dayton mines has decided that hereafter no open lamps will be allowed. This decision comes too late to be of any benefit to the sixteen men who are dead, and to the sixteen households which have been plunged into mourning. The calamity should be a warning to other mine-owners, and to other miners.

THE BEAUTIES OF STATE CONTROL IN TEXAS.

Superintendent Maddox of the city's electric light and water plant of Austin, Tex., reports that at Rusk penitentiary, where the pipe is made for supplying the city's system, the city's pipe inspectors report that out of sixty-four sections of the four-inch pipe examined forty-six were rejected, and out of sixty-four sections of six-inch pipe fifty-six were rejected.

THE WORCESTER ELECTRIC LIGHT CO.'S UNDERGROUND WORK.

Mr. H. H. Fairbanks, treasurer of the Worcester, Mass., Electric Light Co., writes us that the company have been building conduits of the National Conduit Co.'s cement lined type, which are intended to cover the business section of the city, especially that portion where overhead wires are a hindrance to the firemen in case of a fire. These conduits will contain all classes of wires representing the different services of the company—arc, alternating and power. The Worcester Co. has done this under no compulsion from the city, but considered it better policy, in spite of the large expense, to do it now rather than wait and be forced into it by the city authorities.

THE COSTLINESS OF THE LOGANSPORT, IND., MUNICIPAL PLANT.

THE allowances made by the council, upon the recommendation of the electric light committee, for repairs and maintenance, foot up over $1,500, which would mean an expenditure of something like $30,000 for the year. Unless the cost can be reduced, the expense of maintaining the plant and operating it is going to exceed the receipts. The complaint is made that the plant is already short of power, and that before the city can realize on its investment, much more powerful engines will have to be provided. The *Pharos* gets this information from a gentleman connected with the department.—*Logansport Pharos.*

"Enclosed please find draft for subscription to THE ELECTRICAL ENGINEER for 1896. Your motto must evidently be 'Advance,' for that accords with the impression conveyed by your paper during 1895."—HENRY G. STOTT, Buffalo.

MISCELLANEOUS.

ELECTROPLATING AND ELECTROTYPING IN THE UNITED STATES.

BY MARTIN BRUNOR.

BELOW I give a complete statement in regard to the extent of the electroplating industry in the United States drawn from the data in my possession. Owing to the increase in the use of new processes there has been a very material addition to the number of establishments, operatives, and electrical machinery. This statement does not include the electrotyping, etching, and jewelry trades, which, as is generally known, must use dynamos in connection with their product.

Establishments	392
Aggregate capital	$38,388,560
Value of plant	$2,226,482
Value of land	$167,817
Value of buildings	$142,362
Machinery, tools, &c., value of	$1,222,455
Live assets	$2,846,528
Miscellaneous expenses	$383,715
Average number of employees	2,708
Wages	$1,632,246
Officers, firm members and clerks, males, above sixteen years of age	600
Wages for above	$436,938
Officers, firm members and clerks, females, above fifteen years of age	190
Wages for the above	$6,471
Operatives, skilled and unskilled, males, above sixteen years of age	1,834
Wages for above	$805,628
Operatives, skilled and unskilled, females, above fifteen years of age	128
Wages for above	$192,000
Children operatives	103
Wages for above	$16,802
Piece-workers, male, over sixteen years of age	96
Wages for above	$48,125
Piece-workers, female, over fifteen years of age	24
Wages for above	$10,434
Cost of materials used, about	$1,256,000
Value of products, including receipts from custom work and repairing	$3,433,806

The approximate number of dynamos in use is 600, equalling a power of 60,000 amperes.

Since the publication of the *Practical Electroplater*, wherein I disclosed the process of removing the green from jewelry, a large number of the smaller jewelry establishments, employing from five men up, have introduced dynamos of a quarter to a half kilowatt, which is sufficient for their needs, the larger establishments using one to two kilowatt machines. The latter are comparatively few, as the quarter and half kilowatt machines are those most in use. As near as I can estimate, the number of these smaller concerns is near 500.

There are about 300 electrotypers, using 350 dynamos of 200 amperes each, equalling 70,000 amperes, but it would be hard to say how many men are employed.

CONTEMPORARY ELECTRICAL SCIENCE.

IT is not often that we can record the discovery of a simple law, and when it does happen it appears surprising that it was not discovered before. Such a law is enunciated in a paper by Robert Lang in *Wiedemann's Annalen*, No. 11, on the dielectric constants of gases and their chemical properties. The specific inductive capacity K of a gas is determined by its valency. If s is the sum of the valencies of the atoms composing the gaseous molecule or the molecular group, then $(K-1)/s$ = a constant $= 123 \times 10^{-6}$ for all gases at normal temperature and pressure. $K-1$ may be called the electrification number, since it represents that portion of the electrostatic strain which is due to the presence of matter. CO_2, N_2O, and CH_4, having the same valencies, have the same values for K. For CO it is smaller, and C_2H_4 greater, in the proportions of 3 : 4 and 3 : 2 respectively. Hydrogen, being far removed from its critical temperature, occupies a slightly anomalous position. Herr Lang gives a very interesting and suggestive theoretical explanation of the new law.——F. Linde discusses the validity of the Clausius-Mossotti formula for specific inductive capacities in the case of liquefied gases, including CO_2, N_2O, Cl, and of vaseline oil, benzol, and toluol. Plotting the calculated and observed values in curves, the latter are all found to curve the wrong way. ——The influence of electric waves upon electric conductivity has been investigated by H. Haga. Tinfoil gratings mounted in ebonite frames had their resistance altered as much as 40 per cent. by electric waves proceeding from an induction coil 50 cm. off. But the strips had to be very close together (about 0.1 mm.), and they must not be stuck on. The original resistance could be very nearly re-established by concussion.——The circular magnetization of iron wires traversed by electric currents gives rise to strong "extra currents," from which the magnetic susceptibility may be calculated. This was done by I. Klemencic. He found that in soft iron the circular is smaller than the axial susceptibility. On hardening the wire by drawing, the axial susceptibility decreases more quickly than the other. In Bessemer steel the circular considerably exceeds the axial susceptibility.—*London Electrician.*

PAST EXPERIENCE WITH STORAGE BATTERIES.[1]

BY FREDERICK RECKENZAUN, E. E.

A DISCUSSION of the storage battery question by this Institute is so appropriate that I sincerely regret that notice thereof reached me only a few hours before the opening of the meeting, due to my absence in Europe whence I have just returned. Being thus able to make only a very brief contribution, couched in general terms, I wish first of all to heartily endorse Mr. Child's communication. While it contains much that has often been pointed out, advocated and demonstrated in the past, the arguments brought out in favor of the storage battery will bear repetition in view of the fact that the majority of engineers in this country have hitherto persisted in neglecting to fairly entertain them.

On the other hand, it must be conceded that there was cause for this neglect. Storage battery manufacturers in this country concentrated their efforts rather upon the records of their selling departments than upon effecting lasting success for their products. The tendency was rather to show highest capacity and smallest weight and bulk, or at least to make claims for these features, regardless of the conditions to be met; and the selection of type, design of auxiliary devices, manner of installation and methods of operation were treated as if of secondary importance. Engineers and customers in general considered the price of storage batteries high, the manufacturers seemed to agree in that feeling and endeavored to economize in all that pertains to the outfit, to an extent which, as we know, proved detrimental all round. Through years of hard experience gathered by that policy, and contrary to the valuable suggestions offered by the work and success of our European colleagues, this state of affairs predominated until at last it is beginning to be recognized that no less skill, care, scrutiny and liberality is essential to success with the storage battery than with the construction, installation and operation of the plants it is to form an auxiliary of. The storage battery demands as much consideration as steam boilers, engines or the dynamos of an electric plant. It resents the assumption that it may be treated on a par with the coal bin as a storage arrangement.

European electrical engineers, who have long ago settled down to the placing of the storage battery in rank with other principal parts of an electric plant, and who are looking upon this country as being foremost in the quantitative application of electricity, wonder why we stayed so far behind them with the storage battery when all we needed to do was to copy from them and multiply. They have various types in successful use, and a number of manufacturing establishments are doing a substantial and prosperous business.

It may fairly be assumed, and the views which I gathered on the subject tend to bear out the assumption, that to the advantages offered by the storage battery, is to no small extent due the fact that direct current central stations continue to largely predominate over alternating current stations in Europe.

Mr. Childs very appropriately referred to the fallacy of taking the loss involved in the storage battery as the basis for the efficiency for the entire plant, where it only yields a portion of its output to the latter.

Such erroneous assumptions as this have helped to retard the progress of the storage battery here, but chief of all drawbacks unquestionably was the lack of durability, which, having now reached a much more satisfactory measure, should at last bring the success which we were so long looking for.

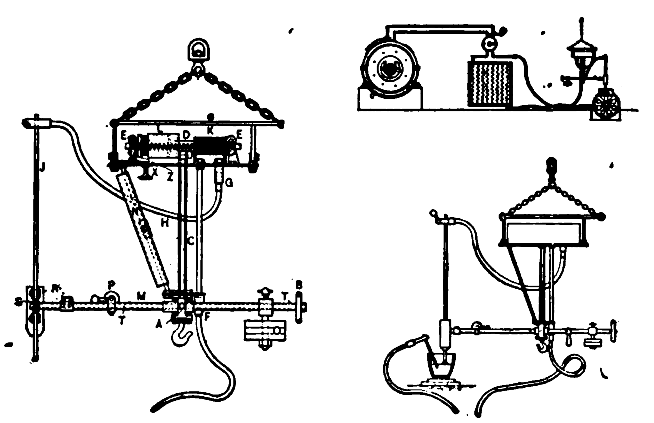
MR. T. A. EDISON in case of a war proposes as our new weapon of offense a stream of water charged with an electric current of 5000 volts, with which to play upon an approaching army. He also suggests aerial torpedoes.

1. A communication presented at the meeting of the American Institute of Electrical Engineers, Nov. 20, 1895.

THE SLAVIANOFF ELECTRIC METAL CASTING SYSTEM.

THE electric casting process devised by Nicolai Slavianoff, a Russian mining engineer, is described at considerable length by A. Lohmann in the *Elektrotechnische Zeitschrift*. The method embodies the principles of both electric casting and welding, and consists mainly in the infusion of metal melted by the electric current upon the surface of a metallic object, whereby the particular parts intimately combine with each other. The fundamental idea comprises the employment of two electrodes, one of which is the material to be cast, while the other may be of a varied nature. The electrode serving as the casting material takes the form of a bar, and is of the same metal which it is proposed to weld. The bar electrode, under the heat of the electric arc, rapidly melts and fills the casting mold underneath. The use of two electrodes, one being the casting metal, is, however, only practicable when the arc is automatically regulated, as will be readily understood. Thus the bar has to be approached in the same proportion as the metal melts and falls down. This operation cannot, however, be performed by hand for any length of time, as a test at once shows. Mr. Slavianoff has, however, devised a method of automatically regulating the arc according as the bar melts away, and which is illustrated in the engraving Fig. 1.

The engraving, Fig. 1, shows the automatic appliance, which is supported in a frame by means of chains and a hook. The lever C carries at its upper end a roller D, arranged between the coils K and L, forming a solenoid. The iron core U is movable horizontally and is carried in the rollers E. Connected at A to the lever C is a hollow shaft, M, carrying the driving bar T, which can be rotated by the hand wheel B. The driving bar T carries at one end a steel toothed wheel, S, against which the metal bar J to be



FIGS. 1, 2 AND 3.—SLAVIANOFF ELECTRIC METAL CASTING SYSTEM.

melted is pressed by means of the roller R, this operation being effected from P. If now, the driving bar T is turned, the toothed wheel S exercises an upward or downward movement upon the casting bar J, corresponding to the direction of rotation of the hand wheel. Arranged on each side of the coils K and L is a spiral spring which, by means of the screw X acting upon the lever Z, can be expanded or compressed. The spiral spring opposes the sucking-in action of the solenoid K and diminishes the sensitiveness of the apparatus. The latter is, to a certain extent, necessary, in consequence of the rapidly varying current strength due to the constant dropping of the melted metal. A similar breaking effect is provided by the movable weight O, connected to the hollow shaft M. The frame N is fitted with colored glass disks so as to protect the eyes of the workmen from the intensity of the arc. The whole of the regulating mechanism is contained in a protective box. The dimensions of the apparatus are: Length from hand wheel to bar electrode, 3 feet; height, 2 feet, and weight, 68 pounds. As will be observed from Fig. 1, the apparatus is constructed as a differential regulator, but the shunt coil is for practical purposes usually cut out. There are, however, cases where two appliance are required for use, and in order to connect the two in series the differential method has been provided.

As already mentioned, the high temperature of the arc rapidly fuses the bar and the liquid metal enters the casting mold. In the same proportion as the bar becomes shorter, the attendant has to bring about the forward travel of the bar. With a little practice this operation becomes easy, as the regulator at once compensates for errors made by the hand. In the main circuit, as indicated in Fig. 2, are also inserted a voltmeter, a resistance, and a pole changer, which play a prominent part in the system. As is known, more heat is developed at the positive than at the negative pole, the ratio being about 2 to 1. This fact causes one to so arrange the direction of the current that the greatest heat shall be produced at the pole chosen as the positive terminal. Experience shows that for melting cast iron, the bar must be connected to the positive pole and the casting mold to the negative. If the direction of the current is reversed, a cast iron is obtained which is white and hard and has little carbon. The resistance, shown in Fig. 2, allows of the spirals being connected in series, in parallel or in groups, and serves to regulate the current strength according to the diameter of the bars operated upon. The current required per square millimeter of cross sectional area of bar to be melted is from 7.5 to 8 amperes, and the pressure from 50 to 70 volts or a mean of 60 volts.

A point of considerable importance in connection with this process in contradistinction to the various electric welding systems is the source of current, as in the former the automatic regulation of the arc allows of the current being taken direct from the dynamo without the use of accumulators. The only condition to be fulfilled is that the dynamo must not have a too sensitive armature, and must be able to deal with sudden changes of load up to 600 amperes. The firm of Julius Pintsch of Berlin, who are licensees both of the Slavianoff electric casting process and the Benardos electric welding system, have used the former method for some time past in their branch establishment in Fürstenwald, on the Spree. The generator in this case is of the Fritsche direct current type, giving, at a speed of 120 revolutions, a maximum of 600 amperes at 70 volts, and a considerable amount of different kinds of work has been carried out.

Among the many applications of the Slavianoff process may be mentioned that of casting small articles without the necessity of melting large masses of metal. This particular sphere of operation is illustrated in Fig. 3, where the bar to be melted is shown arranged in and above a graphite crucible. Other applications of the system include the production of alloys by the use of bars of different metals, the repair of cracks, flaws, holes and worn surfaces; the welding together of different metals, as cast iron on steel, copper and bronze on cast iron, and copper and bronze on steel and iron; repairs of broken parts, locomotive steam cylinders, ship shafts, fly wheels, the conversion of hard white cast iron into soft gray iron, &c. In one instance a large break in the casing of a Westinghouse engine was remedied, and in another a large fly wheel was similarly repaired.

The requisite form for the metal to be cast on to the broken part is obtained first by surrounding the damaged part by a casting mold, the material for which depends more upon the kind of metal to be dealt with. Thus in the case of cast iron the mold is usually made of retort carbon used in the shape of pressed plates 10 mm. in thickness. The material used in the production of iron castings is ordinary commercial bars from 1 to 1½ mm. long. The bits too short for further use in the apparatus are cut into smaller pieces and thrown into the liquid bath.

SOME OF THE OBJECTS AND METHODS OF PHYSICAL SCIENCE.[1]

BY PROF. ALBERT A. MICHELSON, of the University of Chicago.

WE are met to-day to celebrate one of the most important additions to the working facilities of the University of Kansas—the Physics and Electrical Engineering Building.

The association of these two intimately connected and interdependent sciences needs no apology or explanation. It is to-day universally admitted that such an association of pure and applied science is of the greatest mutual benefit. Countless illustrations of the great importance of such close relationships might be given, the mere enumeration of which would take up more than all the time at our disposal. I trust, therefore, that the burden of this brief address will not be misunderstood as implying a bias toward the development of the pure science to the exclusion of its application.

The objects and advantages of the latter are, however, so much more manifest to most of us than the former, that it may not be deemed altogether inappropriate to confine our attention for the present to a few illustrations of the objects which it is the ambition of the student of physical science to attain, and to give a few samples—necessarily very general and brief—of the methods of attacking some of the problems involved.

It is hoped that by this means we may be enabled to form a better conception of the magnificent opportunities which are now placed within our reach by this most wise and generous action of your broad and liberal-minded legislature.

I trust I will be pardoned in using for this purpose illustrations drawn from a single branch of physical science—the one in which the larger part of my own work has been done—and which I confess is to my mind decidedly the most elegant and fascinating of all—from the aesthetic as well as from the scientific standpoint.

The development of the human race is typified by the growth of the child; and as a first evidence of the child's intelligence is exhibited in its first feeble and futile efforts to interpret the sensations which pour in upon its limited understanding, so for ages, in the past history of the race, man has endeavored to observe, to investigate, to classify, to explain, all of the more striking, beauti-

1. An address delivered at the dedication of the Physics and Electrical Engineering Laboratory of the University of Kansas.

ful, grand or wonderful of Nature's works. The immense majority of our impressions are obtained through our sense of sight, and naturally our first efforts were directed to the observation and consideration of things we see. The sky, the earth, the ocean; the sun, the moon, the stars; the gorgeous colors of the sunset; the rainbow, the lightning—what are they? Whence come they? What order is to be found in the maze of their bewildering complexity?

These and like questions have been asked from the time when reason's first feeble efforts began the attempt to solve the problem of existence.

Most of these must remain to our limited intelligence unanswered—perhaps forever unanswerable—save, possibly, the last. To inquire into the *facts* of Nature, to investigate their *relations*, one with another, to ascertain the general *laws* which they obey, to explain their actions and reactions (that is, to *classify* new or hitherto unobserved phenomena among those with which long experience has made us familiar)—these are legitimate and worthy objects of the profound study of the greatest minds.

The physical universe consists of various aggregations of matter concentrated in systems of nebulæ, stars, planets, and satellites, which are separated by immense distances which are almost if not quite void of matter in the sense in which that term is usually understood—as capable of affecting the senses.

The stars affect our sense of sight, and we infer that they are material bodies—and indeed we may even go farther, and say that we know them to be made of the *same kinds* of matter as those with which we are familiar.

Till the most recent times there was no good reason for supposing that the interstellar spaces were not empty voids. But it now seems very probable that these spaces are filled by a very remarkable medium called the ether, the vibrations of which communicate to us, in the form of light and heat, the energy given out by the heavenly bodies. This medium constitutes the one solitary bridge which spans the abyss by which our speck of earth is separated from the rest of the universe.

The probability is very strong that this medium is also a form of matter—possessing, it is true, the properties ordinarily associated with matter in a highly exaggerated form—but differing from it in degree only—not in kind. An extremely ingenious and remarkable theory due to Sir William Thomson, Lord Kelvin, and called "The Vortex Theory," supposes that ordidary matter consists simply of portions of a universal ether differentiated from the rest by their motions.

One step further would lead to one of the grandest generalizations conceivable with regard to the constitution of the physical universe:

There is but one substance—the ether; and the endless variety of phenomena which constitute the physical universe are different modes of motion of its parts.

Of these modes of motion there is one with which we are to a certain extent familiar, from its analogies to the vibrations which produce sound, but which in some respects may better be likened to the motion of water-waves. Of these last, the most familiar example is that of the unruly heavings and tossings of the ocean; but the associations connected with the close contemplation of such motions are not frequently conducive to a state of mind tending toward an appreciation either of its aesthetic features or its use as a scientific illustration. Let us therefore rather retire to a still, smooth sheet of water, and observe the effect of dropping a stone upon its surface. No doubt all of us have at some time watched with interest the ever widening circles of waves, lessening in height as they expand till they are too slight to be visible, or until they are reflected from the shore. The evanescent character of such a wave motion is a necessary consequence of the abrupt character of the cause of the disturbance, and our illustration will be considerably improved if we substitute for the falling stone a motion which is itself regular and continuous, such as that of a pendulum or a balance wheel (*whose regularity* is the basis of their application in clocks and watches). Suppose then a heavy pendulum set swinging in the water; the system of waves to which its motion would give rise would be regular equidistant circles, spreading outward with uniform speed in all directions from the centre of disturbance. If, in the place of the pendulum, a vibrating bell or a tuning fork be substituted, the result will be the same except that since now the recurrence of the impulses is several hundred times as rapid, the waves are very much closer together—the *wave-length* is proportionally less. We naturally associate the term *wave*, with the motions of a water surface; but the signification of the word may be extended to cover any kind of a change which is propagated in any kind of medium. Thus in the case of a sound wave, the medium is usually the air, and the change which is propagated is compression or rarefaction. If the disturbance is irregular, as in the case of a sharp shock or the fall of a load of coal, the resultant sound is a noise. If the cause be regular the result is called a pure musical tone; but if the purity of the tone be carried to the extreme, the effect would be that which I may expect by giving in this discourse too uniform a diet of fact with too sparing a sprinkling of fancy—it will be voted *monotonous*.

In the illustrations given, the condition which is propagated in the form of a wave-motion is something material—palpable; and all the intricate consequences which flow from the simple *mechanical* assumptions may be rigorously calculated by the ordinary processes of analytical mechanics. A striking illustration of the beneficial reactions of practical applications of science is furnished by the advances in dynamo-electric machinery. The vast and continually increasing development of this branch of industry has compelled both scientific men and men of business to familiarize themselves with ideas which but a few years ago had not even a name.

One of the most interesting and promising of these developments is the application of an alternating current of electricity as a source of power.

Upon the practical details of this wonderfully fertile field of electricity—which may almost be considered a science in itself—I do not intend to dwell, but wish merely to utilize the idea of an alternating current as an illustration of the propagation of a wave-motion. The alternating electrical condition which travels along a wire is a true wave.

The fact that ordinarily the length of the waves is enormous—thousands of miles—does not in the least bar it from this classification. The wave-length may readily be found from the known speed with which it travels. This is about two hundred thousand miles per second. Accordingly, if the alternations at the dynamo succeed each other as fast as two hundred per second, the waves will be a thousand miles long; a corresponding sound wave of the same frequency would be only five feet.

Now, if it be desired to produce a more rapid vibration than is obtainable by a tuning-fork, we may use a short, thick, cylindrical steel rod, which when struck laterally gives out a very high tone. If struck lengthwise the tone is so high that it cannot be heard at all. But we may nevertheless calculate its rate, and find that for a rod an inch long this would be a hundred thousand per second. If it were possible to set a rod one thousandth of an inch long in vibration, the rate would be a hundred millions, and then the length of the corresponding electrical waves (supposing that such vibrations could produce them) would be only ten feet. The beautiful experiments executed by the late Dr. Hertz (whose untimely loss is deplored by the whole scientific world) have made it possible to produce and to measure electrical waves still shorter than these and this too without any conducting wire. Imagine now the vibrating rod or its equivalent to be made ten million times smaller; it would then give out electrical waves only $\frac{1}{50000}$ of an inch long. But the vibrating body is now of the same order of magnitude as an *atom of matter* and the length of the resulting electrical wave is the same as that of a *light-wave*. It is thus clear that if a vibrating atom can produce vibrations in the same medium which transmits electrical waves, that these waves would be of the same order of magnitude as a light-wave. But it is proved that both electrical waves and light waves are forms of energy, that both are reflected, refracted, absorbed, and polarized according to the same laws, and that both travel with the same speed. It is impossible to resist the conclusion that they are one and the same thing. If, by any means, it becomes physically possible to replace the minute vibrator by a mechanical device, which will produce the same number of electrical alternations, it may be confidently predicted that the problem of the direct production of light by mechanical power will be solved.

The investigation of hypotheses concerning the constitution of matter, and of the ether, and the true mechanism of light, are among the most important problems in science; and it may be confidently predicted that the time is near at hand when these hypotheses will crystallize from their "mother liquor" of vague speculation into definite and complete working theories. Until this time is reached, however, we cannot hope for any very accurate notion of what light and light waves really are: but we may nevertheless content ourselves with a remarkably exact knowledge of their wonderful properties; and in the meantime make the most of our opportunities in utilizing this marvellously delicate instrument of investigation.

Most of us have at some time looked through the glass pendant of an old-fashioned chandelier and no doubt have noticed the curious "down hill" effect, as well as the brilliant coloring which appears to surround the borders of objects viewed through such a prism. But not even the genius of a Newton could have guessed that a similar experiment *made under appropriate conditions* leads to one of the most wonderful discoveries in modern science. There is an impression among practical people (which however is happily on the decrease) that there is something unreal, unsubstantial—they would express their skepticism by saying "theoretical"—in the conclusions of science; and not infrequently oppose scientific conclusions to those of "common sense"; forgetting that science *is* common sense, refined by subjection to a most rigorous scrutinizing criticism. In the instance just given, crude common sense would be content with the observation that a prism appears to displace the objects viewed and confuses and colors their outline. A scientific man would be content not merely with carefully noting all the phenomena thus casually presented, but would devise ways and means of varying in every possible way all the conditions which he can control in order to eliminate all

unnecessary attendant circumstances, and of bringing into prominent relief the special features which he desires to investigate. This is what is meant by *experiment.*

It is to the genius of Newton that we owe the first accurate experiments on the analysis of light into its constituent colors. This fundamental research, supplemented by the labors of Frauenhofer, Kirchhoff and Bunsen, led to the discovery of the dark and bright lines in the prismatic spectrum, which mark the particular kinds of light which characterize the substances which produce them so that they may be recognized in quantities almost infinitesimal and at distances greatly beyond our conception.

So much has already been accomplished in the use of light as an instrument of investigation that we have come to let our familiarity with the marvels accomplished by its aid diminish our wonder at the results.

One hundred years ago it might have been admitted to be within the bounds of possibility to obtain some rough notion of the distance of the sun, and perhaps of the "fixed stars"; or even an approximately correct idea of their motions in space;—but what enthusiast would be so rash as to predict that it might be possible to know the composition and structure of the sun and the constitution of the stars?

Think of it a moment. Light travels one hundred and eighty-six thousand miles between two ticks of the clock; it would reach us from the moon in less than two seconds, and from the sun in eight minutes. Yet so extremely remote are even the nearest of the stars that, even at this inconceivable speed, their light takes four years to reach us; while for the great majority of them the light by which we now see them was dispatched long before we were born!

And notwithstanding these immense intervals and these distances inconceivably great—so faithful a messenger is light, that he has preserved intact the marvellous record of all that has transpired in those remote spheres of fire. Though the messenger has a language which is perfectly competent to deliver his errand, he is not sufficiently modernized to translate it into "United States" for our especial benefit, but insists that if we would know its burden we must humbly learn to decipher his hieroglyphics.

This we have just begun to do. We have almost learned the alphabet; we have actually succeeded in putting together a few words; and have even caught a glimmering of meaning in a few whole sentences—sentences of momentous import, telling of cyclones of fire, tornadoes of boiling metal, conflagrations vastly greater than the whole world! Such are the mighty truths revealed in reward for the labors of the patient investigator. Such are the incentives to further labor in the hope of new and perhaps even more wonderful results.

From suns and stars to molecules and atoms seems perhaps a long and sudden jump—but our Ariel makes but little distinction in dealing with these magnitudes, be they great or small. The telescope has furnished us with most of our knowledge of the structure of the stellar universe. The spectroscope—when we learn to interpret its indication—will give us an insight into the structure of the molecule. A body or a system of bodies has more than one mode of vibrating—theoretically an infinite variety of ways; but these various kinds of vibrations stand in fixed relations to one another, depending on the shape and structure of the bodies and the forces which hold the parts in place. In the simple case of a cylindrical rod, we may have four such infinite series; and it would be possible—knowing, from the sounds thus produced, the periods of those different modes of vibrations—to deduce from them the *form of the vibrating body* and the motions of its parts. Now we have a number of striking evidences of regularity and of remarkable numerical relations between the vibrations of the light emitted by certain substances, as evidenced by the bright lines which they show when examined by the spectroscope. Does it seem visionary to trust that the accumulation of such evidence is an important step in the desired direction?

It is never safe to affirm that the future of physical science has no marvels in store which may be even more astonishing than those of the past; but it seems probable that most of the grand underlying principles have now been firmly established and that further advances are to be sought chiefly in the rigorous application of these principles to all the phenomena which come under our notice. It is here that the science of measurement shows its importance—where quantitative work is more to be desired than merely qualitative results. It is an almost daily task of the scientific student and investigator to reply to queries concerning the practical use of such an extraordinary degree of refinement as is shown in almost every modern scientifically conducted experiment. It is frequently admitted that these uses are not practical—but I would not concede even this much. Two thousand years ago there was no occasion for divisions smaller than an inch. Two hundred years ago measurements smaller than one-sixteenth of an inch were required of only the most careful workmen. Twenty years ago—outside of scientific measurements—a thousandth of an inch was nil. To-day an error of this magnitude in one of our modern engines would mean all the difference between success and failure. If now it be granted that for *scientific* work, upon which every practical advance depends, the order of accuracy is from ten to one hundred times as great as this, who can say what will be required two hundred years—nay, twenty years hence? These are undoubtedly sufficiently weighty reasons for the time and care which are indispensable in properly conducted scientific work—but unquestionably, the most important reason of all is, that by such work, and by such work alone, must we look for the steady onward march of science, by which alone truth is to be dug from its well and placed upon a foundation more solid and enduring than the pyramids.

An eminent physicist has remarked that the future truths of physical science are to be looked for in the sixth place of decimals. In order to make such results possible the student and investigator must have at his disposal the methods and results of his predecessors, must know how to gauge their value, and to apply them to his own work; and especially must he have at his command all the modern appliances and instruments of precision which constitute a well-equipped physical laboratory—without which results of real value *can* be obtained, but only at immense sacrifice of time and labor.

The science of Astronomy appeals far more powerfully to most minds than does physical science; which indeed to many is scarcely known even by name. The former is as old as history. Its wonders have compelled the attention of mankind from the earliest ages, and it is but a natural consequence, that at the present day no important city in the civilized world is without its richly endowed observatory where its trained corps of astronomers is able to study the phenomena of the life of suns and worlds and their distribution in space and time. It is only in very recent times that it has begun to dawn upon the mind of man that there is another world only one degree less complex and wonderful than the stellar universe—the world of molecules and atoms.

For the study of these infinitesimal systems of pigmy stars we have, it is true, no telescope, or even microscope to help us; but little by little we are constructing a powerful logical engine which is destined at no very distant day to bring the revolutions, rotations, and oscillations of these minute orbs as clearly to the mind's eye as are now the motions of the world and suns of the greater physical universe.

When will the Kepler come to marshal the present ever-increasing array of facts and queries into one great and consistent whole? When will a second Newton appear to solve the riddle of that complex microcosm we call a molecule? This, their problem; to penetrate, as far as it is permitted to human reason, that wonderful mysterious whole we call matter, whose solar systems are molecules, whose worlds are atoms.

LITERATURE.

The Wonders of Modern Mechanism. By Charles Henry Cochrane. Philadelphia, J. B. Lippincott Co. 1896. Cloth. 8vo. Illus. pp. 402. Price, $2.

This book sums up in a popular way, yet with clearness and accuracy, the recent advances of industry and invention. The object is to exemplify what has been done within the last year or two in various branches of engineering, and to indicate the directions in which the foremost inventors of the age are working. Electricity is liberally included and little of importance has been overlooked. It is natural that some parts of the book should incline to the nature of "glittering generalities," but Mr. Cochrane has a practical mind and has pinned the facts down whenever he could catch them. A review of this sort from year to year would be very useful. The illustrations, like the text, are clear and instructive.

LETTERS TO THE EDITOR.

THE WORTH OF THE ELECTRICAL ENGINEER.

I have read with great interest your excellent circular on "The Selection of an Electrical Paper for 1896." Your logic is irresistible. I hardly appreciated all the good things the ENGINEER brought to my table, until I read in condensed form the *résumé* of the menus you served in 1895! Truly you gave us palatable dishes, and the finishing touch was the advent of your Data Sheets.

I congratulate you upon the far-sightedness which led you to give these sheets to a hungry public almost "without money and without price."

I believe in THE ELECTRICAL ENGINEER, for I've tested its worth. To my mind, not the least of its advantages, is the fact that it stands as an apostle of high-toned journalism and does not traduce or malign competitors. It's clean and worthy of imitation.

You are at liberty to publish this if you see fit. Please renew my subscription and that of the Standard Air-Brake Company and the Moore Electrical Company for 1896.

VOL. XXI. NEW YORK, JANUARY 1, 1896. No. 400.

CONTENTS.

1895.

THE past year has been one in which electrical development was noteworthy chiefly in the field of power transmission. It saw the starting of the plant at Niagara Falls, an event of vast importance, and the work at Folsom and other places. Besides this, a large number of factories, iron works, docks, etc., have been equipped with individual power plants, and central stations have more than ever devoted their energies to building up a motor patronage.

The electric railway field has seen three striking advances in the equipment of the Nantasket Beach steam branch of the Consolidated Road; the Mt. Holly steam branch of the Pennsylvania Railroad and the Baltimore tunnel of the B. & O. In each instance, electricity has proved an emphatic success. During the year also, conduit street railways have come rapidly forward as mechanically and electrically operative; and even the storage battery has again been put forward as the best method of all. The Chicago Metropolitan Elevated also went into successful operation.

In lighting there has been little that is really new, but hope is hovering eagerly on the edge of the future when we are to have a light that is cold and lamps that never burn out. The growth of arc lighting has not been conspicuously large, but the dynamos are bigger than ever. Alternating arcs and constant potential arcs have been greatly improved, and some new constant current arcs of merit have made their way into the market. A bad feature has been the low price of incandescent lamps. Good lamps cannot be made and sold at the average quotations, and the customer will only get the poorer quality he is paying for. Another feature which has attached attention during the year is the advent of electrically produced acetylene, as a proposed competitor to the incandescent lamp. Nothing has been done towards its practical distribution thus far, though many appear anxious as to its possible influence on the industry.

The "boom" expected in telephony as a result of the disappearance of patent restraints has not been seen or felt. There has been a brisk outburst of competition and many places heretofore without exchange service now enjoy it; while private telephone lines have multiplied apace. But in many of the larger cities, the attempt at competition has brought rates to a level which will not support life in any system; while elsewhere the existing exchanges have done marvels in the way of bettering their service. New York City strikes us as an example of intelligent and progressive management, and the rates and inducements offered by the Metropolitan Co. are such that rivalry is rendered well-nigh impossible. Competing exchanges in any city have always appeared to us an example of two bodies occupying the same space; and it is certain that the public will reward with its exclusive patronage the service that is steadily the best.

Telegraphy during 1895 has been notable chiefly for the extension of the Postal Company's lines and the opening by it of several fine new offices with the latest modern equipment. The Western Union's business meantime has not shown any revival, although the introduction of copper circuits has gone on. This present year sees the expiration of the old Western Union-American Bell contract in November, and curiosity is aroused as to what may happen, for the experience of 1895 has shown that many things are possible.

OPERATION OF THE PENNSYLVANIA BURLINGTON BRANCH ELECTRICALLY.

THE Mt. Holly-Burlington branch of the Pennsylvania road, equipped with Westinghouse apparatus, appears to be yielding excellent results. With even the temporary apparatus, the railroad people have had a number of surprises, such as stopping with air brakes when going down a 2 per cent. grade on a rainy day at 48 miles an hour, in 300 ft. The train on that occasion consisted of one motor car and two trail cars, one of the latter being a regular P. R. R. passenger coach and the other a P. R. R. standard baggage car, altogether a train weighing 65 tons. The same train was started on a 2 per cent. grade (up grade) and acquired a speed of 45 miles an hour in a run of about one mile. These figures and data, as well as more of similar nature, would seem to indicate the entire practicability of supplanting steam by electricity on long as well as short hauls on steam roads, and the ease with which electricity could handle even the largest trains.

ARTIFICIAL LIGHT PROBLEMS.

ONE of the great problems of the age held up to courageous and farsighted inventors is the production of light without heat; and the light of the glow worm has become the standard of reference, as it were, by which the new light is to be judged. But it seems that this is wrong and that the public is destined to a rude awakening. We are now told that, after all, the glow worm light is not the one to be sought after, and indeed is not nearly as good as can be attained from the present type of incandescent lamp. This, of course, does not refer to the efficiency of the lamp, but to the character of the light from the purely physiological standpoint. It has long been known that the candle power of a source of light as measured in the photometer is no true index of its illuminating effect on surrounding objects of various colors. All reds and browns, for example, absorb the larger part, in fact nearly the whole of the blue, green and violet light which falls on them; consequently in a room finished in warm tones the wall absorbs a disproportionate amount of the light from the incandescent lamp and reflects only 15 per cent. of the light which falls on it, making the room look gray and gloomy. A scarlet is reduced to a crimson, and a mixed red to gray by the blue of the electrically heated carbon when the light falls directly on it.

Now, by studying the reflection spectrum of a colored room by daylight and determining its absorption area, and then obtaining the same area by tinting the glass of the globes, we may obtain an artificial light of ortho-chromatic scale. At the same time we bring down the over-reflection of violet from the whites, blues and blue-greens and consequently we relieve the eye strain, the pupil expands and more light is admitted

Based on this reasoning Dr. W. H. Birchmore, whose highly interesting contribution is printed elsewhere in this issue, claims that it is possible by means of certain combinations to alter the spectrum of transmission just as Abbe and Zeiss have altered that of refraction—by which they have perfected photograph and microscope objectives—and thus adapt the emitted spectrum to the room. This is not surrounding the filament by a ground-glass or colored bulb or globe making the light monochromatic, but it is equivalent to making an algebraic equation of certain wave lengths.

This can be done without seriously impeaching the candle power as measured by the Bunsen photometer, but on the other hand by increasing the amount of reflected light and relieving the eye strain at the same time, the amount of light entering the eye is vastly increased.

As it stands now, the reflection spectrum value of a 16 C. P. lamp upon reds, and browns, is not quite as much as that of a paraffin test candle, while from violet it is near 50 times. Thus violets are too bright and all bright colors are painful to the eyes, reducing the pupil. Dr. Birchmore has developed a simple method of tinting glass by which he claims that the color scheme of a room by incandescent lamp light can be made the same as by day, every color taking nearly or quite its true value. A room finished in warm tones can be habitable in the evening, and the ghostlike white rooms to which decorators are being driven as a last refuge from the violet light be avoided.

If Dr. Birchmore's principles shall prove to be well founded in fact, and experiments to that end indicate that they are,—the usefulness of the present sources of illumination will be largely increased, the incandescent lamp especially being specially adapted to the proposed method of bulb tinting.

LOWER STREET CAR FARES.

THE introduction of electricity on street railways has done much for the public, and one of the greatest boons has been the longer distances over which it has enabled passengers to travel for the same amount of money—usually the single nickel. At the present time, however, there are evidences of dissatisfaction in many cities, and a widespread agitation is in progress for lower fares. In fact, the reduction has already begun. In Detroit, on the new road, the average cost of a ride approximates to a three cent fare, and Dr Everett now offers a corresponding rate for his projected new system in Cleveland. In Detroit also, on the old Citizens' system, Mr. Tom L. Johnson is offering four tickets for 15 cents, and in Chicago the General Electric road is selling seven rides for 25 cents. The new Buffalo Traction Co. has just been given a franchise with a four cent fare clause in it, and so it goes all along the line. The signs of the times are unmistakable.

But there remains a good deal to be said on the side of a maintenance of the time-honored 5 cent fare, and not the least of the arguments is found in the necessity that many of the city roads may soon be under to adopt conduit or kindred methods of operation. The change will be costly, and it cannot be carried out unless the companies are able either to do the work out of revenue or can sell new stock. The income from 3 cent fares is inadequate and capital will not be readily elicited in face of diminished returns.

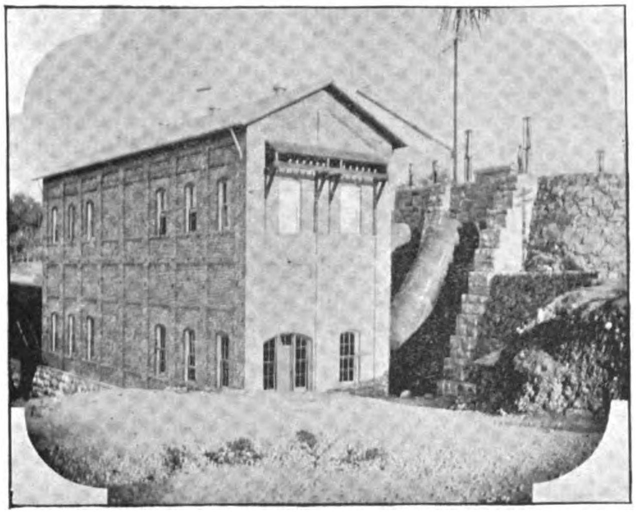
It seems to us that among the rational ways of dealing with the situation is that of making special rates for work people morning and evening; and that another proper and scientific way is to grade the length of travel by the fare. It is to be borne in mind also that a lower rate will not tend to make things more comfortable for passengers. On large lines at busy hours, the cars are already dangerously close, and any increase of travel cannot lessen the headway but must on the contrary intensify the crowding.

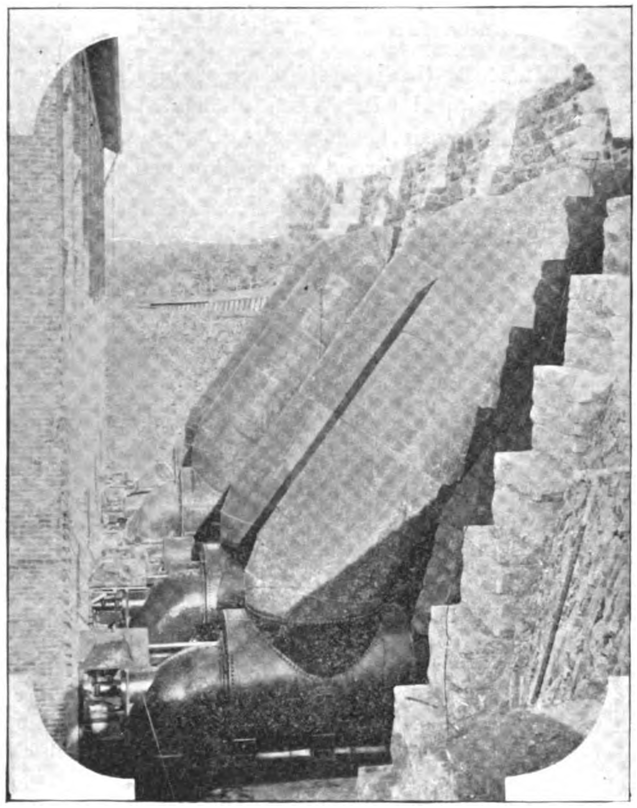
As a matter of fact, the chance of picking up extra nickels, has led the trolley companies frequently to extend their lines unduly, and to put down tracks which cannot earn a revenue. The lower fare will check this expansion to the detriment of modest house owners and will restrict the suburban growth which has been so notable during the last seven or eight years. A 3-cent fare is not much benefit to anybody who has to pay a higher rent or real estate value in consequence of its enforcement. So, too, with regard to general accommodations, it is obvious that so sharp a reduction in income will greatly lessen the ability of a corporation to improve its plant, renew its cars, or go on introducing the many little novelties that have made the trolley so beneficial an influence in city life.

POWER TRANSMISSION.

THE HYDRAULIC PLANT OF THE FOLSOM-SACRAMENTO TRANSMISSION.

One of the most successful long distance 3-phase transmission plants thus far put into operation in the United States is that between Folsom and Sacramento, California. By damming the American River a fall 70 feet has been made available, capable of delivering 10,000 H. P. The distance of transmission from the dam at Folsom to Sacramento is 23 miles and by employing a potential of 10,000 volts, 1,000 H. P. can be transmitted over three wires of No. 1 B. & S. gauge each, four such circuits being employed.





FIGS. 2 AND 3.—POWER HOUSE AND TURBINES, FOLSOM-SACRAMENTO POWER TRANSMISSION PLANT.

Our issues of Feb. 13 and July 31, 1895, gave full details of the electrical equipment of this plant At the latter date but one forebay was completed, but on Oct. 1, the remaining forebay was finished, giving the plant its full operating capacity.

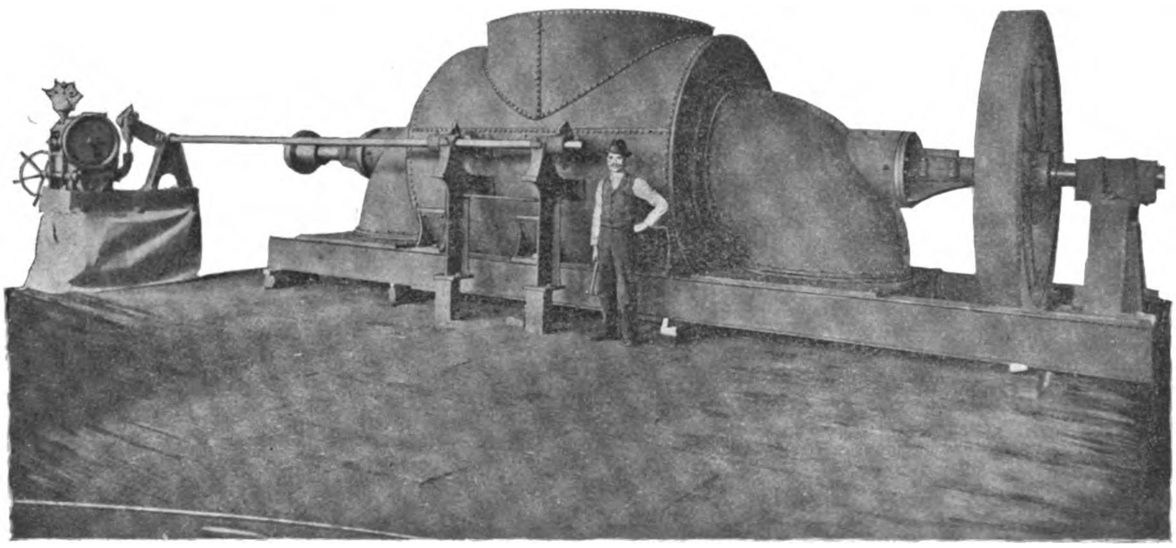


FIG. 1.—MCCORMICK TURBINES USED IN FOLSOM-SACRAMENTO TRANSMISSION PLANT.

The hydraulic plant consists of four pairs of phosphor bronze McCormick turbines, built by the S. Morgan-Smith Iron Works, of York, Pa., under contract with the Pelton Water Wheel Co. Each of these pairs, illustrated in the accompanying engraving, Fig. 1, has a capacity of 1260 H. P.

With an available head of 55 feet, the wheels make 300 revolutions per minute, the water being led to the turbines by 8 ft. inlet pipes made of $\frac{5}{8}$ inch steel.

An interesting feature in connection with these wheels is the addition of fly-wheels to assist in the governing. For this purpose each pair of wheels is provided with a 10-foot steel fly-wheel weighing 10,000 pounds and giving a peripheral speed of 9,425 feet per minute. Heavy steel tires shrunk on the rims provide for the centrifugal strain.

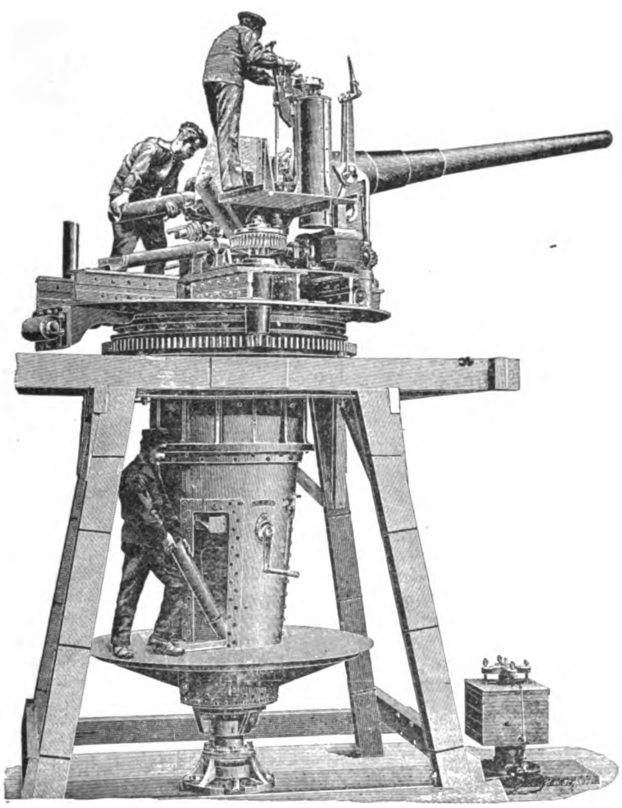
The exciting dynamos are run by two small special wheels. The Faesch-Picard governor, similar to that employed in connection with the Niagara 5,000 H. P. dynamos is here used.

Each of these turbines is coupled direct to a 750 K. W. General Electric 3-phase generator. These machines have 24 poles and at 60 cycles deliver current at 800 volts to the step-up transformers which transform it to 10,000 volts used on the line.

Our engraving Fig. 2, gives a view of the power house, showing the inlet tubes and cross-arm which carries the insulators for the main line wires.

CANET ELECTRICALLY WORKED TURRET.

SINCE less than a year ago, says *Engineering*, the progress made by Mr. Canet in the introduction of his system has been more rapid than might have been expected, not only with the French marine, but with foreign governments, and at the present time the Société des Forges et Chantiers de la Mediterranée has completed, or is completing, no less than 40 turrets of various sizes for different vessels; among these the most important are the Latouche-Tréville, the Jaureguiberry, the D'Entrecasteux, the Pothuan, the St. Louis, the Capitan Prat, the Skjold, and the Carlos V. The turrets most recently completed are intended for the armament of the coastguard ship Skjold, belonging to the Danish fleet. The installation consists of three turrets and the associated machinery; one of these is for carrying a 24-centimetre (9.45 in.) gun, and two turrets for guns of 12 centimetres (4. 72 in.). All of these are closed turrets, and as in other installations on the Canet system of the same class, they are provided with hand, as well as with electrical gear, so arranged that either can be employed by shifting a transmission clutch, so that it is possible to pass from one to the other method of driving, without any appreciable delay. Electrically worked gear has been applied, in the case of the larger turret, to the mechanism for training the 24-centimetre gun, as well as to the ammunition hoists; in the smaller turrets it is only used for training the 12 centimetre guns horizontally. Ammunition is raised to the gun platform by means of an endless chain and carriers worked by hand, a method which assures an ample supply for these lighter calibres. The device employed for the training of the guns is the "electrical cartridge.



CANET ELECTRICALLY WORKED TURRET.

The excellent results obtained on the Latouche-Tréville with this apparatus have been fully confirmed by the recent trials on board the Skjold that were carried out at Havre, in presence of the Danish Commission appointed to examine and receive the vessel. These trials have certainly demonstrated the reliability, under all conditions, of the Canet-Hillairet-Huguet "cartouche electrique." The man in charge of the turret is always enabled to hold it under complete control; not only is he able to arrest the movement of the platform suddenly at any desired moment, no matter what velocity is imparted to the turret, without creating any shock or reaction to the heavy moving mass, but he is able at will to make the fine adjustment in training with great facility and speed through distances less than one-fortieth of a degree. Tests of this class were repeatedly carried out at the trials in the presence of a large number of French and foreign naval officers. By the special arrangements introduced into the Canet turret, and the care with which all the parts making up the system are counterbalanced, the power required to revolve the moving parts is reduced to a minimum. The work of turning the turret of the 24-centimetre gun, with its heavy platform, armored protection, and the gun itself, is performed with a 15 horse-power electric motor, or rather that is the nominal power of the motor provided, but as a matter of fact only about two-thirds of this energy are required. A 8 horse-power electric motor is sufficient for effecting all the operations of training the 12-centimetre guns and their lighter turrets. The ammunition hoist of the 24-centimetre gun is driven by a separate electric motor of 8 horse-power; this motor is controlled by a special type of controller which imparts the intermittent motions required for charging the hoist and raising and delivering the ammunition on the gun platform; the action of the commutator is entirely automatic, and it is provided with a safety device. The illustration that we publish shows the arrangement of the turret, mountings, training gear, and ammunition hoist on board the Skjold; the smaller turrets are similar, with the exceptions already described.

POSSIBILITIES OF POWER DISTRIBUTION IN PITTSBURGH.[1]

A PAPER containing novel ideas was read last evening by L. B. Stillwell at the meeting of the engineers' society in Carnegie Hall, Allegheny. The paper went to prove the possibility of doing away, by the use of electricity, with the smoke and soot that hang like a pall over Pittsburgh. Although the author did not admit the justice of the claim that a good plan, to be adopted, must be more economical than methods already in use, he stood ready to prove that his proposition was actually cheaper. The paper was on the "Possibilities of Electrical Distribution of Power in Pittsburgh." Mr. Stillwell started out with the assumption that these three propositions are not necessary to demonstrate, but are already admitted—that Pittsburg is an exceptionally smoky city; that smoke is largely due to imperfect combustion in boiler fires, and that electricity is an efficient and convenient means of distributing power from a central station.

Imagining a committee of the engineers' society suspended in a balloon over the city, basking in the sunshine, while below lay the city, a spot of soot on the earth's surface; supposing the committee to be possessed of full information regarding the poor average economy in the use of fuel, the loss of coal by breakage and weathering, and the low percentage of power derived from the combustion of coal, and delivered to the steam engine from the boiler, Mr. Stillwell concluded that the committee would decide that no small-power plants producing smoke ought to be tolerated, and that every wheel of industry in Pittsburgh and Allegheny should be turned by energy developed in a central station, where the production of smoke could be absolutely avoided. The committee, he said, would not take the view that this plan ought not to be considered, unless its advocates could demonstrate that it would directly and immediately save money for those using the power, but would be inclined to think that a man does not, necessarily, possess the right to impose smoke and soot upon his neighbors merely because it has been his habit to do so.

From a series of calculations Mr. Stillwell deduced that in the central wards of Pittsburgh and Allegheny a marked saving for the users of power would result, in the case of all but very large steam plants, from the substitution of electric motors supplied with energy from a 20,000 horse-power central station. He suggested two plans, one a central station located 10 miles from the court house and one installed in the city, preferably on the banks of the Monongahela near the coal supply. He considered the second plan the better.

To install a 20,000 horse-power electric plant in the city would cost, Mr. Stillwell estimated, $3,000,000, and the total annual charges, including operating expenses, maintenance, taxes, insurance and interest on investment, would not exceed $600,000. Such a plant would be capable of delivering to the premises of the users of power 17,000 horse-power. Allowing for three per cent. for losses in the transformers and 15 per cent. for average losses in the motors installed by the users of power, the plant could deliver at the shafts of these motors 14,000 horse-power at any given time. As all the customers would not always be using the maximum of power which their motors could develop, it should be possible to supply from such a plant motors aggregating not less than 20,000 horse-power.

Allowing annual dividends of 10 per cent. on the $3,000,000

1. *Pittsburgh Post*, Dec. 20.

investment, to be added to the annual charges, making a total of $900,000 per annum, the cost per horse power, calculating that the plant would supply 20,000 horse-power, would be $45 a year. This figure, Mr. Stillwell said, is considerably under the average cost in Pittsburg, excluding from consideration plants using more than 2,000 horse-power.

THE NEW ELECTRICAL PLANT IN THE U. S. PRINTING OFFICE AT WASHINGTON, D. C.[1]

BY W. H. TAPLEY, CHIEF ELECTRICIAN.

THE plant consists of one 187½ K. W. direct-connected generator and three 80 K. W. belted generators, all of the most improved compound multipolar Westinghouse type. The 187½ K. W. generator is directly connected with a Westinghouse compound condensing engine of 250 horse power. The two machines occupy a floor space of 21 by 7½ feet. The 80 K. W. generators are driven from a line shaft, which is belted to a 250 horse power compound condensing engine of the marine type. Friction clutch pulleys are used for driving these generators, thus giving the greatest flexibility to the plant by allowing the stopping of any one of the three generators while the others are in use. These, independent of the direct-connected generator, are capable of furnishing all the necessary power as well as light needed in the office in case a total breakdown of the direct-connected unit occurs. The total capacity of the four generators is 8,500 50-watt 16-candle power incandescent lamps—more than sufficient for all lighting and power demands.

The peculiarities of the work of the office make necessary a sectional rather than a general system of electric lighting. With this end in view, the wiring has been done entirely on the "crib" system. This affords a uniform distribution of light throughout every division of the office, the rooms farthest away from the generator station being equally as well lighted as those near by. So perfect is this result that nowhere in the building does the variation from the switch board to lamp exceed 2½ volts, nor is the variation in any one room ever more than one-fourth to one-half volt, no matter how many or how few lamps may be burning on the circuit. The capacity of all main trunk lines and feeders is so large that circuit regulators on the switch board are not required.

To make up any loss from generator to lamp, the generators are overcompounded 1½ per cent., and their makers guarantee that no greater loss than 8 per cent. will occur from full to no load. Thus there will be a constant voltage at the lamps, whatever may be the existing conditions, insuring full candle power and the long life of the lamps. We are thus able to get full benefit of the current generated and not have a considerable portion of it consumed in rheostats that the system may be kept in balance.

The crib system has been extended to vertical mains as well, thus allowing the disconnecting of one side of the circuit without interrupting the service throughout that circuit while in use. The crib system of wiring not only increases the flexibility of the plant, but minimizes the possibilities of interruption of work, and also equalizes the distribution of current to the lighting mains.

In carrying out the instructions as to the application of electrical power, the office will use at present seventy Crocker-Wheeler electric motors of one-sixth horse power to 30 horse power, aggregating 225 horse power.

To secure full protection against any possible interruption of work, except through a total failure of steam power by accident, a suitable electrical switch board of special design became necessary. This board is one of the largest and most complete in the country. It presents many peculiar features and fully meets the exactions of the service here, which will not permit interruptions during the sessions of Congress. The switch board is divided into five panels—three for lighting and two for power. It is so constructed that an additional panel may be made without changing any of the connections. There are two sets of bus bars extending the entire length of the board—one for the use of the lighting circuits and the other for power circuits. By the use of a switch the two bus bars can be connected so as to make one continuous bus bar, and power and lighting circuits may be run together and from one generator should occasion therefor occur. Each generator is connected to the switch board by a double pole double-throw switch, thus allowing any generator to be used for power or lighting as occasion may require. Each feeder circuit is also controlled by a double-pole double-throw switch, giving every circuit throughout the building two sources of current and providing for an uninterrupted system either of light or power. Under normal conditions all lights will be run from one set of bus bars and the power circuits from the other, but when both power and lighting load become sufficiently small so that the combined demands of both are not in excess of the power of one 80 K. W. generator, all work will be so divided by the switch board as to make it possible to run everything from one generator. This board allows the changing from one generator to the other without any interruption to the service in the building or the running of the generators in multiple.

Each panel is provided with a standard Weston volt and ammeter. Each power circuit is supplied with a round pattern Weston ammeter. There is also connected to the lighting service a recording voltmeter. For testing insulation of each circuit there is a special reading in ohms marked on one of the voltmeters, thus enabling a daily log to be kept of the condition of each circuit of the plant. The measuring will be done by drop-of-potential method, and not only will each individual circuit be tested, but each leg of each circuit, a suitable switch being provided for the purpose.

More than 20 miles of wire of the best kind was used in the circuits, and during its erection full use was made of every precaution known that would render property and life more safe.

The insulation test of this entire system with all cut-outs in circuit will reach, under ordinary conditions, 8 megohms.

One of the special features of this electrical plant is the transmission of power by electricity. In all cases where it was possible so to do without interrupting work, we have connected motors direct to the machines themselves, doing away entirely with the use of belting and its attendant losses, disadvantages, and dangers. We find that the printing presses and some of the other large machines were never driven to their full capacity by belts, and that since they have been geared direct to the electric motors nearly double the amount of work has been done on some of them.

In gearing motors direct to printing presses we have not only secured the advantage of displacing belting, but enabled the pressman, by the use of a reversing regulator, to have absolute control of his press when making ready, and move the bed plate forward or backward, as desired, and without the help of a laborer. The speed of the press can also be regulated at will.

The two principal advantages of electric motive power over shafts and belts are the reduction of the friction load to a minimum and the independent working of each machine. Under the shaft-and-belt system the breaking of a belt often necessitated the shutting down of all the mechanical divisions.

To each motor is attached an automatic cut-off, so that accidents are not liable to occur through carelessness of employees. A still further safeguard is the automatic circuit breaker, which prevents the overloading of motors.

In the erection of the plant every approved electrical device has been used. The short period during which the new plant has been in operation prevents full statements as to the amount of current and power consumed by each division of the office and the actual amount of power saved, as compared with the old system.

1. Report to T. E. Benedict, Public Printer.

UTILIZING THE WATER POWER OF THE LAKE OF THE WOODS.

Among the water-power enterprises lately developed, one of the most noteworthy in many respects is the work of the Keewatin Power Company at the outlet of the Lake of the Woods, Canada. The company's constructions are of gigantic proportions, and are expected to supply a minimum of 40,000 horse-power in the dryest seasons. The Lake of the Woods covers an area of 3,000 square miles, is fed by the Rainy River and many small streams draining an area of about 30,000 square miles The ambitious design of converting this great lake into a mill pond and its outlet into power flumes by an enormous dam across the Winnipeg River has already been carried to a successful issue. This dam, with its long row of massive granite piers built on the solid rock of the river-bed, is a structure as permanent as the rocky shores of the river. It has been constructed with all the requisites for retaining and regulating the flow of water, and the head maintained for the flumes is about 21 feet. The commercial and industrial possibilities of this 40,000 horse power supplied by nature in a district surrounded by abundant wooded land, and in the excellent farming country between Winnipeg and Lake Superior, can scarcely be overestimated. The many inventions which have multiplied the uses of wood fibre will be advantageously turned to practical use in a district where cheap power and an abundance of the pulp woods are found together. The ever-increasing harvests of the Northwest will also, in the natural course of events call for increasing milling capacity, and cheap power will be a material factor in transferring to the western continent the work of grinding wheat for the European consumers.

ELECTRIC POWER AT JACKSONVILLE, FLA.

THE application of electricity to power purposes in Jacksonville is rapidly extending. During the last week Mr. Johnson Law has installed two Eddy motors, one for Dick Oldham and one for the Hilditch branch laundry on Bay street. The Cleveland Furniture company has also ordered from him a five horse-power Card multipolar slow-speed motor for the new factory in LaVilla.

THE CHICAGO GENERAL RAILWAY CO. has decided to sell seven tickets for 25 cents.

ELECTRIC TRANSPORTATION DEPARTMENT.

MR. YERKES ON MUNICIPAL OWNERSHIP OF STREET CAR SERVICE.[1]

"I DEEM municipal control of street car lines undesirable. It is not for the best interests of the people, and the operation of street car lines by public officials would be impracticable in this country. It is not a matter which admits of discussion. To contend any industry can be operated as well or as economically by public officials as by private corporations is ridiculous. The very fact the officials are continually changing would defeat any such plan. I know of no other business where education is so necessary as in that of street railroads. Few even of those people who have been connected with them for years, are thoroughly conversant with the requirements of their successful mangement. It is a business full of detail from the top to the bottom, and requires a lifetime of study and attention to fully understand. How, then, could it be expected a public official appointed, say, every two years, would be able to direct the operation of a system? It would take him that long to fully comprehend the duties of the employés.

"As for a proper understanding of the necessities, the economies, and the management of the roads, it can only be had by experience and a natural aptitude for the business.

"The great railway systems are successes only because they are intelligently managed. The net earnings divided among the stockholders is but a small portion of the gross receipts, and a little bad management could easily eat up that and more.

"But the City of Chicago manages its own water-works and electric light system," was suggested.

"Yes," said Mr. Yerkes, "and we all know there are no large industries in this city so poorly or extravagantly managed as those under the control of the city government. The cost of supplying the people with water is much greater than it would be if done by a private corporation, and while we have no data in this city with which to compare the work of the Water Department, yet when placed beside the cost to corporations supplying towns with water we see how much more economical the corporation management is. There is no doubt there is enough money wasted to make a good dividend for a private corporation."

"But the electric light system?"

"In our electric light department," Mr. Yerkes grimly replied, "the most absurd condition is shown. This is one place where we can make a comparison between the municipal and private operation of an article used by the public. The plant of the city electrical department cost much more than it could have been built for by private corporations. In fact, the prices paid were most extravagant.

"The operation of the electric plant is to-day a disgrace to this community. There is not another large city in the country, and I doubt if there is one in the world, where it costs so much for public lighting as in Chicago, and I know of no city where the prices are as low as those of our private corporations. Counting the interest on the plant, and the cost of operating the total cost to the city is the stupendous sum of $165 a lamp a year. There is but one thing in excuse of this extravagance, and that is the wires in the heart of the city are underground. But allowing for this, when we compare this cost with the prices charged by private corporations in other cities the result is startling. In St. Louis the city pays the local company $74.75 a lamp a year. In Cincinnati the price is $70, and in Indianapolis $85. I have no doubt the local company in this city would be glad to make a contract to supply our light at a reduction of fully 50 per cent., providing it could make a contract for such a length of time as would warrant it in putting in an underground system in the heart of the city."

Here Mr. Yerkes took up the political aspect of the question and continued: "If it is not economical or practicable to operate these industries by the municipality there can be only one reason why it should be done, and that is to support an army of politicians and their supporters, who, we all know, care little for work and who are of no service to the industry they may pretend to be engaged in. Suppose the street railway systems of Chicago were turned over to the city, who would operate them? Perhaps the Commissioner of Public Works or his Superintendent of Street Railways, a person who must have a political pull to be appointed to the position. He would, in all probability, be a man who knew but little if anything about the business.

"Then who would be his employés? The conductors, gripmen, and motormen would be the people who were valuable in the different wards in times of election. These thousands of conductors, who are really the cashiers for the railways, would be men who owed their position to the head of the department or the Alderman of their ward. The situation, while serious to contemplate, would be laughable.

"Then what a power it would give the political party in control! The North and West Side street car systems, together with the elevated and branch lines, employ 6,000 men. The other lines perhaps 4,000 more, making a total of 10,000 in the city. At election time every man would know a change of administration meant his probable discharge. Then, again, if it were necessary for the administration to have more votes, at least 50 per cent. more people could be placed in positions as extra men, and for other purposes.

"The best object lesson of this sort of thing," continued Mr. Yerkes, "I know of was given in Philadelphia when the municipality purchased and ran the gas works of that city. For twenty-five years the trustees of the city gas works practically ran the city. The law provided the Council should elect the trustees who managed the gas works. But the trustees nominated and elected the Council. It was a difficult matter for any one to be a member of the Council unless he had the approval of the gas trustees.

"In Europe, where there is a monarchical system of government, the plan of municipal control of corporations might succeed. The head of the department would be appointed by the ruler and be held strictly responsible for his acts. The best talent of the kingdom would, in all probability, be employed. In Europe, except in England, most of the railroads, both steam and street, are run under government supervision. But the conditions there and here are radically different. There it is necessary for the government to have constant control of the railroads. Hundreds of thousands of troops are constantly under arms. They are being constantly moved from post to post, always in readiness for what may happen. The street railways naturally come in for the same sort of treatment as the steam roads, but they are so insignificant in comparison they are not taken into consideration."

"But what of the socialistic contention for municipal ownership, regardless of whether it is practicable or not?"

"The establishment of corporations composed of the people to manage the business interests of this country was one of the first practical steps in establishing a free government—a government of the people, when they could band together to organize manufacturing concerns, transportation companies, and any industries which require large amounts of capital. As the country has grown, the demand and necessity for the enlargement of the powers of corporations has grown also. They are owned by the people, as they should be, and every man or woman who has the ability can be an owner in them.

"I believe there would be no worse blow that could be struck our liberty than to place under municipal or governmental control the transportation and other corporations of this country. It would soon build up a government based upon the tyranny, strength, avarice, and despotism of the head of that government, and the people themselves would have little or no voice in it."

1. Abstract of an interview with Mr. C. T. Yerkes, *Chicago Tribune*.

THE DANGERS OF GUARD WIRES.

IN a recent letter to Mayor Clarke, of Manchester, N. H., on the subject of guard wires, the local street railway having been ordered to string them wherever its trolley wires crossed others, Capt. Wm. Brophy, electrician of the Wire Department of Boston said: Guard wires, when properly installed, do, in a measure, prevent electrical contact between the trolley and other wires, thus preventing danger to fire alarm apparatus, telephones and other instruments, and in that way preventing injury to persons using them, and at the same time reducing the danger from fire. But they are not an absolute safeguard for the following reasons: (1), they are not always properly insulated from the pole and trolley wire; (2), there are not many hours in the day when the trolley does not come off the wire. In such cases, the trolley, span and guard wires are connected electrically through the medium of the trolley pole, thus making the guard wires as dangerous as the trolley itself.

One of the worst burnouts that ever befell the Boston fire alarm telegraph occurred in that way. One of the circuits came in contact with the guard wire at some point of the West End Railway system. The trolley left the wire at some other point, and the pole rested against the trolley and guard wires. As the latter is one continuous unbroken line, current was conveyed to the point where the fire alarm wire was resting on it, and destroyed every instrument on the circuit.

Accidents of this kind to telephone and other circuits are quite frequent.

It is often, as you know, necessary to cut the trolley and

guard wires when they are an obstruction to the fire department. In all such cases the span and guard wires become as dangerous as the trolley; and a very large number of the accidents that have occurred to the members of your department, when on duty, are, as you well know, due to this cause.

I think on the whole the guard wires, as erected at the present time, are often a real source of danger to the firemen and others.

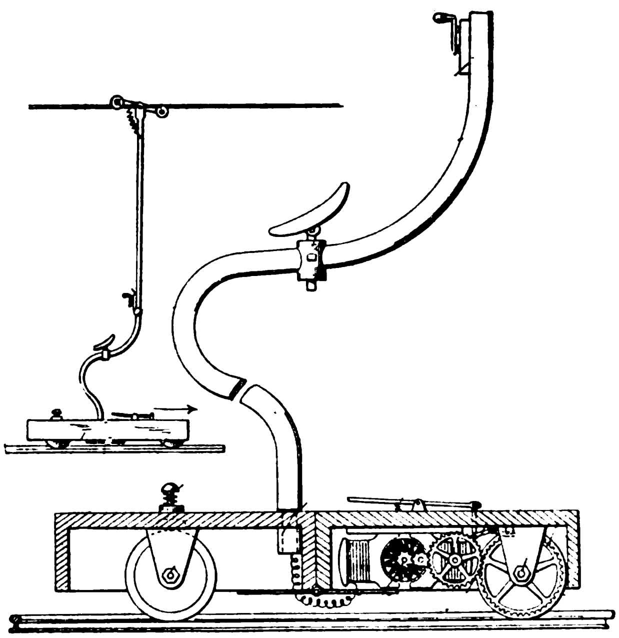
If they are erected, it should be in the following manner: They should be insulated thoroughly from the span wire that supports them, and if iron poles are used, insulated from them also in a most thorough manner. They should be divided up into sections or lengths of 500 or 1,000 feet, and an insulator or circuit-breaker placed between the different sections. These insulators will prevent the flow of current from one to the other.

The trolley wire should be divided up and the sections insulated from each other in the same manner, with a suitable switch at the junction of the connection to connect or separate them. In that case the current should be cut off from one or more sections, and the trolley, guard and span wires cut or handled with perfect safety. The location of these switches should be made known to the chief of the fire department and his assistants, and they should have access to them in case of fire. This will prevent accidents to firemen and others when it is necessary to cut the wires, when they are an obstruction.

Mr. J. H. Bickford, of Salem, Mass., also wrote that guard wires were generally as much a menace as a protection.

THE "PEDO-ELECTRIC" TROLLEY.

The "pedo-electric trolley," as it is called, which has been recently patented by Robert T. Oney of Charleston, West Virginia is designed to run on a single rail and furnish individual trans portation over a trolley line. The car, illustrated in the accompa nying engravings, is small, readily handled, and of single con



THE ONEY PEDO-TROLLEY.

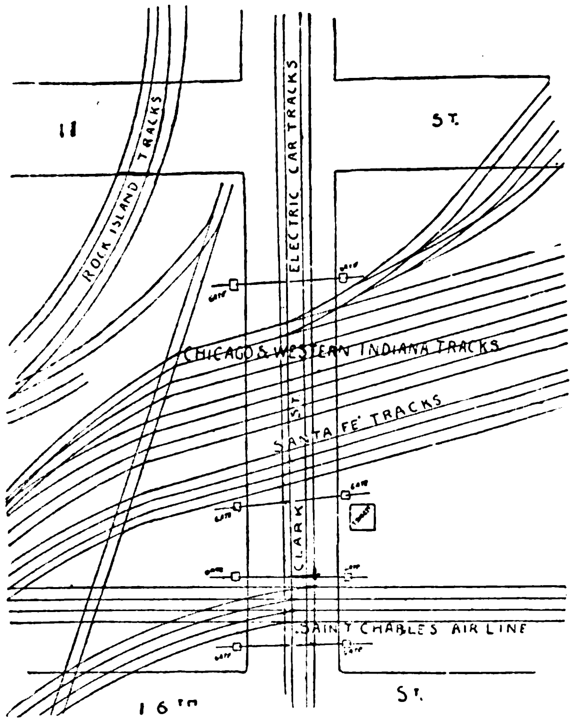
struction, is arranged to accommodate a single passenger, who stands in the rear of the trolley pole, and controls the machine, making it go fast or slow according to his requirements by means of the usual rheostat and a suitable switch and brake.

The carriage consists of two parts, hinged together and having a carrier-wheel on the front and rear axles. The axle of the front carrier-wheel has a gear to which motion is transmitted from the armature shaft of the motor, to which current is led in the ordinary way from the trolley wire. The trolley pole carries an insulated seat or rest for the passenger and insulated handle-bars, near which a rheostat is fixed. The two frame parts of the carriage are made of wood or other insulating material, and the passenger stands with one foot on the forward frame-section and one on the rear, a brake, adjacent to the rear foot being arranged to act on the rear carrier-wheel and a switch lever being so placed that it can be conveniently operated by the forward foot of the passenger, who thus has full control of the current and can regulate the speed of the carriage.

When the carriage is not in use and is to be removed from the rail, the two pivoted frame-sections are closed, and they form a complete inclosing case. The carriage can be so adjusted as to travel only a predetermined distance, and the passenger is thus prevented from riding further than the distance called for by his ticket.

A DANGEROUS TROLLEY CROSSING IN CHICAGO.

NOTE was made in a recent issue of THE ELECTRICAL ENGINEER, as to the intolerable delays experienced by street car lines crossing steam tracks in Chicago. The accompanying cut brings out very



CLARK STREET TROLLEY CROSSING, CHICAGO.

clearly the other element of danger. How it is possible to operate a trolley road in safety and on schedule, under such conditions, it is hard to imagine; and it would seem that every argument would demand a change. This is the crossing which was made the subject of a special message by Mayor Swift to the Chicago City Council recently, in which he recommended all trains be made to come to a full stop before crossing Clark street. It is by all odds the most dangerous crossing in the city. Railway men whose roads do not use it say they know of no other like it anywhere. Running diagonally across Clark street at the intersection of Sixteenth are two tracks of the Atchison, Topeka and Santa Fé and four of the Western Indiana. Over these every train running in and out of the Dearborn street passenger station must pass, and all the empty coaches, sleeping, dining, mail, baggage, and express cars must be switched, going to and coming from the yards. There is no yard room for their accommodation between Sixteenth street and the station.

THE TROLLEY AS A GARBAGE CART.

The idea advanced by Mr. Lewis Stockton that the new street railway company, if granted a franchise, give the city of Buffalo the privilege of using its tracks between midnight and 6 A. M. for transporting garbage and ashes is not a bad one. It has been urged before that it would be advantageous if the garbage and ashes could be brought to stations located in different parts of the city, and from them transported on cars over the trolley lines to the places where the city's refuse is disposed of. The collection of the garbage and ashes could be made much more quickly under such a system and with less annoyance to the public. Of course a considerable saving in the expense of collection could be effected if the city were to have the free use of tracks for this purpose. Traffic need not be in any way impeded if the garbage cars were operated only at the time of night when there is a long interval between the running of passenger cars.

THE "LITTLE CONSOLIDATED" RAILWAY CO., of Cleveland, is putting in a 1000 H. P. Elwell-Parker generator to be driven by a Globe Iron Works engine.

THE LOWELL & SUBURBAN STREET RAILWAY is preparing plans for an addition to its plant of 2000 H. P. in boilers, engines, and generators.

A 24-FT. PLATE-STEEL FLY-WHEEL.

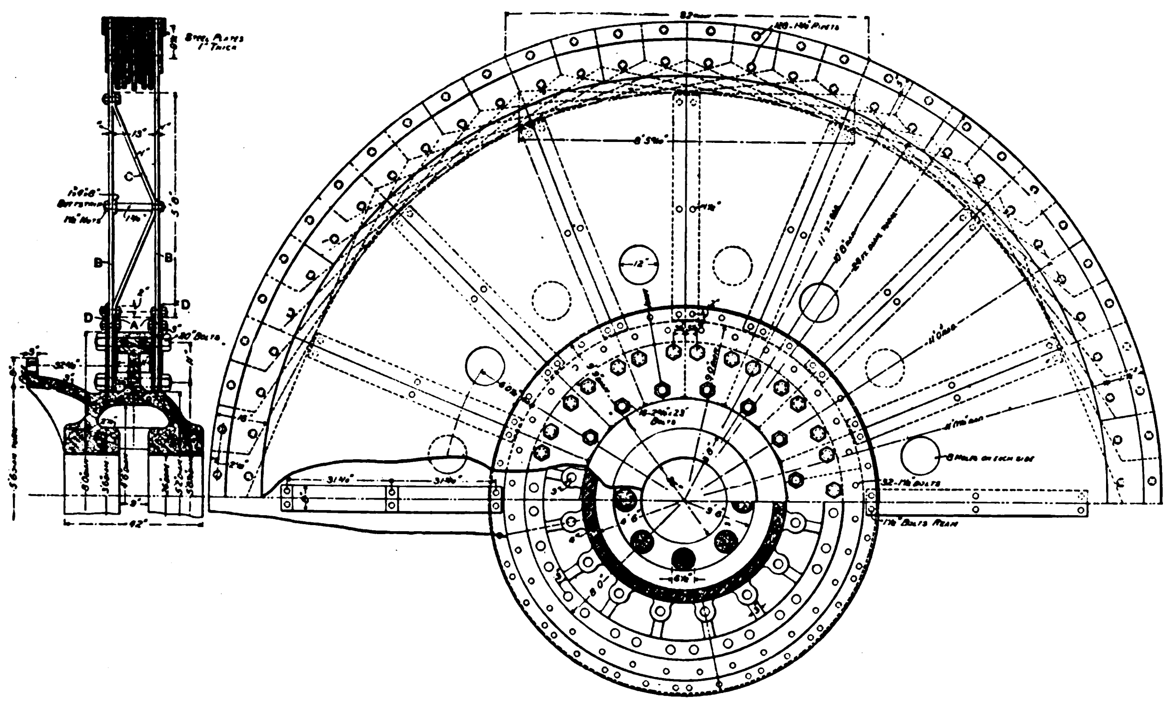
THE constantly recurring accidents with cast iron fly-wheels even when built up has led many engineers to seriously consider their abandonment for heavy work, and to substitute for them wheels built up entirely of wrought iron or steel. The latest example of this kind is a wheel built by the E. P. Allis Company, of Milwaukee, illustrated in the accompanying engravings, for which we are indebted to the *Railroad Gazette.* This wheel is built of plate-steel, 24 feet in diameter and is intended to be attached to a 32 x 62 x 60 in. cross-compound engine, directly connected to a General Electric generator, for the West End Street Railway Co., Boston.

This is a departure from the ordinary fly-wheel construction which consists in casting the wheels in segments and bolting these together. In this wheel there are no internal strains to weaken it such as might occur in cast wheels. This in connection with other features of construction will permit greater velocity of rim than in wheels built up of cast segments and spokes bolted together. The speed at which this wheel is intended to run is 75 revolutions a minute, giving a speed at the circumference of 90 ft. a second or a little over a mile a minute. The weight is distributed as follows:

Centre	33,000	pounds.
Web plates	47,700	"
Rim	69,300	"
Total	150,000	"

Fig. 1 is a side elevation of half the wheel and a longitudinal section through half the hub, while Fig. 2 is a transverse section of half the wheel. The hub is made of cast-iron, and is 8 ft. extreme diameter. Surrounding this hub are two plates, A, Fig. 2, which are split on the diameter as shown in Fig. 1. These plates are of steel 1 in. in thickness and 23 in. wide. From these plates extend the web plates, 16 in number, to the extreme outside diameter of the wheel. These plates, D, Fig. 2, are also 1 in. in thickness and are faced along the edges so as to form a good joint. Between those on the opposite sides of the hub are 1 in. by 8 in. truss pieces C, Fig. 2, bolted at the ends with two ⅞-in. bolts, and having at the centre two 1¾ in. bolts to act as struts. These bolts are turned down to 1⅛ in. on the ends. These truss pieces are put at the joints between the web plates. Outside of the web plates are two cover plates, D, Fig. 2, 1 in. in thickness and 27⅛ in. wide, which are also split on the diameter as plates marked *A*. Through the outside cover plates D, web plates B. and inside plates A, are 40, 2¾-in. bolts spaced so that three of them will come on each segmental web plate. Besides these bolts there are 48, 1⅛-in. bolts on each side through the cover and web plates. The section of the rim between the web plates consists of, 18 1-in. steel plates placed side by side and joining on the ends as shown in Fig. 1. The joints of these plates overlap as shown in Fig. 1, each plate covering seven joints of the others. Outside of the web plates on each side the rim are 1 in. x 12 in. plates forming a cover around the entire rim; this cover is made up of eight pieces. Still outside of this is another strip 1 in. x 5 in. also extending all the way round the wheel. 1¾-in. rivets hold the plates and the rim together. They are countersunk as shown in Fig. 2.

By this construction the increased strain on the rim between spokes is avoided, the web plates forming, as it were, an infinite number of spokes. Other details and dimensions are completely given in the accompanying engravings.



FIGS. 1 AND 2.—A 24-FT. PLATE-STEEL FLY-WHEEL.

THREE CENTS FOR STANDING UP.

According to recent announcement, there appears to be a compromise idea, says the *Jersey City Journal*, on the street car controversy in the city of Chicago, in which there is possibly a modicum of sense. The suggestion for this comes in the form of a proposition that the fares be reduced to three cents in cases where the passengers cannot get seats, and a resolution introduced at the city council's last meeting, provides that "all street railroad companies be required to charge not more than three cents fare when no seat is furnished, and in no case to charge more than five cents when a seat is furnished. It also provides that a passenger having paid a three-cent fare for standing room, can if a seat be subsequently vacated, occupy the same without paying additional fare." Now, while the first part of the proposition may have some measure of sense in it, the second part certainly has not, for the simple reason that it is not exactly fair that a man who has paid for a stand-up only, should receive a seat which is worth two cents more than the amount which he has paid. We very much doubt if the three-cent fare idea will actually prevail for many days yet to come. Certainly a mix-up of the kind proposed for Chicago will not be a smooth working arrangement. And yet there is force in the suggestion that a ride without a seat may reasonably be deemed worth less than a ride which includes one.

REWARDS FOR PHILADELPHIA TROLLEY MEN.

The Directors of the Hestonville, Mantua and Fairmount Passenger Railway Company gave $2,500 to its employés on Dec. 24, for the fidelity and ability displayed during the recent strike. The Hestonville Company is the only line in Philadelphia not embraced in the Union Traction system, and while the strike of the latter company's employés was in progress it was the only street-car line that was operated regularly. As a consequence, the traffic was very heavy. There are 300 men in the employ of the company.

THE LONG ISLAND TRACTION CO.'s properties were sold last week for $5,500,000 to John G. Jenkins, president of the First National Bank of Brooklyn, a member of the Reorganization Committee. The capital of the road is $30,000,000, which it is proposed to reduce to $20,000,000. The new company will be called the Brooklyn Rapid Transit Co.

STEAM AND TROLLEY IN CONNECTICUT.

An interesting situation which may soon develop some acute steam-trolley rivalries, exists between Hartford and New Britain, two cities eight miles apart, and the latter with a population of some 22,000. In Hartford and neighborhood are street railway trolley systems with some seventy miles of track to a considerable extent paralleling the New Haven and New England steam roads. New Britain has in the city and neighborhood about twenty miles of trolley track paralleling for about nine miles the New Haven and New England Roads and chiefly controlled by the New Britain Central Railway and Electric Company. The New Britain and Hartford trolley systems have, however, not thus far been connected, owing partly to an impeding decision of the courts, and partly to the refusal of the New Britain city government to allow a certain street to be used unless the local trolley company submits to city taxation. Pending further decisions of the court the New Britain Company has surveyed a line to Hartford, and, should it win in the legal contest, will immediately connect the two cities and compete between them with both the New Haven and New England steam companies.

Since the New Haven secured control of the New England, the interests of the two steam companies are practically identical. Starting at a point only about a mile from New Britain, they have four tracks running to Hartford side by side. A short double track spur will give them four tracks between the stations of the two cities. It is known that the New Haven Company contemplates, should the New Britain Trolley Company succeed in getting through its line, the equipment with electricity of two of the four tracks and putting on what would be in effect a trolley express service, operated at short intervals between the two cities. The legal questions involved must soon be settled by the Supreme Court of the state, and a decision of the local tax case is expected in a very few days. Should the trolley company win, prompt action by the New Haven Company to thwart, if possible, its trolley rival is almost certain to follow. Its contingent design of using two of the four tracks for trolley service is analogous to that heretofore planned in connection with its four tracks into Boston.

ELECTRICITY FOR A STEAM ROAD IN MAINE.

The Norway & South Paris Electric Street Railway Company, Maine, has chosen a committee consisting of Hon. H. L. Shepherd of Rockland and Gen. George L. Beal of Norway to confer with the officials of the Grand Trunk about operating the branch railroad from South Paris to Norway by electricity in the place of steam. The plan proposed is to run the cars on the branch with an electric motor and to dispense entirely with the steam engine now used. The company propose to haul the freight cars by electric power over the branch to the present station. A part of the passenger traffic may come the same way and the road be extended from the station through Cottage street to Main street where it will connect with the present electric railway forming a belt line between the two cities. The larger portion of the passenger traffic and the mail and express will be conveyed over the street route now running. This may be the first place in Maine to run freight and passenger cars by electricity over a road built for steam driven cars.

REWARDS AT WESTPORT, CONN.

Sixteen conductors and as many motormen have received cash prizes for good work, at Westport, Conn., the sums ranging from $5 up to $25. The men have won the prizes by freedom from accidents, excellent handling of cars, running on schedule time, neatness, cleanliness and courtesy to the public.

CAR GATES UNCONSTITUTIONAL IN MISSOURI.

Judge Burgess, of the Supreme Court of Missouri, has ruled that the State law requiring street railway companies to protect the front platforms of their cars with gates or guards, is unconstitutional. The decision is based upon a clause in the State Constitution requiring that all matter contained in the act itself must be embodied in the title to the act. The idea of this is that when a law is passed anyone may know by reading the title just what is contained in the act itself. It has been found that in the law requiring gates on the front platforms there were a number of things treated of in the body of the bill to which no reference was made in the title.

President Baumhoff of the Lindell railway says that the decision will not in any way affect the conduct of the companies.

"We have always had gates on the front platforms of our cars," he said, "and intend to have them right along for our own convenience and protection. We always held that the law did not apply to the front platforms of trail cars. Our claim was that the law referred only to the front platforms of motor cars. I think every railroad in this city so regarded it, but many of them voluntarily put gates on the front platforms of trailers. We are not anxious to injure people at all, as it is generally very expensive, but we did hold that the law referred to was unconstitutional and it was fought on that ground. All roads, I fancy, will go on just as they have. The only difference will be in our liability for injuries."

BUFFALO TRACTION CO.'S PLANS.

"If we get a franchise," says John K. Page of the Buffalo Traction Company, "we shall put on 200 trolley cars at the first crack. We shall order 125 closed cars and 75 open cars, and they'll be ready as soon as the road is ready to be operated. The cars will be similar to those on the Broadway line in New York City—the best type of the Stephenson make. We'd order more cars, but the builders told us they couldn't possibly supply us with more than 200 in one year."

"SMOKER" TROLLEY CARS IN JERSEY.

The Consolidated Traction Company, of Jersey City, is considering the plan of running combination express and smoking cars. The forward part of the new car will be for the smokers and the latter part for the conveyance of parcels. "Of course," said Mr. Young, recently, "we cannot carry big stuff, and even the question of freight carrying is being bitterly contested in Newark. But as soon as that trouble is settled, and we expect it will be adjusted soon, then we will run these combination cars. It will be a great convenience for business people if they want to —say, ship parcels from Jersey City to the Oranges or Bayonne. We, of course, cannot deliver the parcels from door to door, but some express company will doubtless take this in hand and ship their packages at our depot, and at the end of the line deliver them. Just as soon as we can settle this matter of running express cars we will accommodate the smokers at the same time."

STREET TROLLEY CARS PROPOSED ON BROOKLYN BRIDGE.

The Nassau Electric Railway Co. seeks to secure the exclusive privilege of running trolley cars over the bridge from Brooklyn to New York, and says it can handle 40,000 persons in this way in an hour, besides rendering the trip easy and comfortable.

TO SELL MILWAUKEE STREET LINES.

Judge Jenkins has signed a decree of sale in the foreclosure proceedings against the Milwaukee Street Railway Company. The plaintiffs to this action are the Central Trust Company, New York; the North American Company, Nelson Robinson, and the Milwaukee Street Railway Company of New Jersey. F. M. Hoyt is appointed special master to carry the decree into effect. The amount of the consolidated mortgage to be forclosed is $8,906,000 with interest due, and on which default was made, $9,425,292 64, bringing the amount down to Dec. 19, 1895. The road must be sold to the highest bidder in the hall of the courthouse, the date and hour to be fixed by the master.

PITTSBURGH STREET RAILWAY CONSOLIDATION.

The Pittsburgh Traction Company, the Duquesne Traction Company and the Central Traction Company are now practically part of the Consolidated Traction Company. The stockholders of the three corporations have voted to lease their properties to the Consolidated Company for a period of 950 years. The consideration aggregates an annual rental of $340,000. The total capitalization reaches about $20,000,000.

ELECTRIC RAILWAY WORK IN IOWA.

The Waterloo & Cedar Falls Rapid Transit Co., per J. H. Rafferty, writes:

We expect to be in a position to entertain propositions from electrical engineers and contractors within a short time. On account of the heavy snow during the winter in this section of the country, we think it advisable that engineers and contractors see this ground before snow falls. We expect to commence the construction of this work as early as the weather will permit us in the spring. We expect to construct about fifteen miles of road.

MR. LEVI PERKINS, president of the Holyoke, Mass., Street Railway Co. is dead, at the age 64.

MAYOR PINGREE of Detroit is proposed as head of a big national association "to fight the encroachment of street car corporations." This ought to be the kind of gubernatorial or presidential boom he is after.

LOWELL TO LYNN.—Trolley cars are now running on regular schedule between Lowell and Lynn, a distance of 26 miles making the trip in about $2\frac{1}{2}$ hours, and apparently finding plenty of patronage along the route.

TELEPHONY AND TELEGRAPHY.

LEGAL ASPECT OF THE TELEGRAPH AND TELEPHONE SERVICE.[1]

BY WALTER CLARK, Judge, Supreme Court of North Carolina.

THE author begins by asserting that it is unconstitutional for the telegraph and telephone services of the postal system to be operated by a private monopoly, or in any other manner than by the Government. He adds:

"When the Constitution placed the postoffice in the hands of the Government it conferred exclusive operation, and with it all means of operating it to the best advantage. The same clause of the constitution of the United States (Art. 1, sec. 8) which empowers Congress to declare war, raise and support armies and a navy, to coin money, regulate commerce, and borrow money on the credit of the United States, includes the provision to "establish postoffices and post roads." If the power of the Government is exclusive as to the other provisions it is so also as to the postoffice, for all these powers are conferred by the same clause and by the same words—in one breath as it were. The numerous decisions of the United States Supreme Court holding the power of Congress over the postoffice and the carrying of mails to be exclusive, render unnecessary any discussion of an undisputed point. It is interesting to note, however, that in 1886, the Hon. John C. Calhoun, the leader of the strictest constructionists, who denied to the general Government all powers not clearly granted, in a report made by him as chairman of a committee of the United States Senate, said: "It must be borne in mind that the power of Congress over the post-office and the mail is an exclusive power." These words have been cited and approved by the Supreme Court of the United States in the case of ex-parte Jackson so recently as the 96 United States Reports on page 734. The bestowal of the exclusive right and duty to operate the post-office carried with it the exclusive right and duty to use all the agencies that would make the post-office most highly efficient, as such agencies from time to time should be improved or invented. On this principle the first telegraph line was built by a Congressional appropriation under a "strict construction" administration (Polk's), and the telegraph belonged to the Government, 1844–47; and when under mistaken notions of economy it was then turned over to private ownership, Henry Clay, the great Whig leader, and Cave Johnson, the Democratic postmaster general, were among the public men who went on record as earnestly protesting against such a step. Indeed the Supreme Court of the United States in a unanimous opinion (Pensacola vs. Tel. Co. 96 U. S. 1) has held that the telegraph came within the grant of power to establish the postoffice."

Justice Clark holds that the postoffice is as exclusively a Governmental function as the army or navy, or the department of justice. Yet the Government operates only the slow, antiquated non-paying part of the postoffice, leaving the taxpayers to make up an annual deficit of six or eight millions; while the improved, up-to-date part of the postoffice, the rapid or electric mail (the telegraph) is operated by a private monopoly and pays a heavy dividend on its watered stock of one hundred and fifty millions—ten times the actual value of its plant. With wire costing less than $10 per mile there is no reason, he alleges, why the Government should not own a line to every postoffice in the Union.

1. *December "Arena."*

PAYING TAXES ON ERIE TELEPHONE SUB-CO. STOCK.

The commissioners have given their decision in the famous Erie telephone tax case which has been pending for five or six years. The petition was for abatement of taxes assessed on Messrs. Charles E. Adams, J. W. C. Pickering, Levi Sprague, A. C. Russell, Francis Jewett, Charles J. Glidden and J. W. Bennett, all of whom were Erie directors in 1889, the time to which the petition applies.

The commissioners' decision is against the petitioners and this means that they will each have to pay the sum of $2,576, making a total of $18,032, unless the superior court to which they will probably take the case decides otherwise. The petitioners held in trust the stock of the various sub-companies in which the Erie holds a controlling interest.

In 1889 the assessors decided to assess each of the seven directors for one-seventh of the stock held by them in trust. The amount of the tax thus assessed was $2,576 each, or a total of $18,032. The assessors at the same time refused to accept the stock in the Erie Company held by the men in question.

Thinking that the assessment upon the stock of the sub-companies was unjust, the seven directors refused to pay it. They contended that the stock assessed was of no value except that it served as the basis of the Erie Company; and also, as the plants of the various sub-companies were taxed in the state in which they are situated, that they should not be subjected to double taxation. As the directors refused to pay the tax, the assessors proceeded to attempt to collect it. Only the tax for 1889 is involved, as since that time the directors of the Erie have each paid a tax upon one share of the sub-companies and their Erie stock has been accepted for assessment.

TELEPHONES FOR THE BROOKLYN BRIDGE CARS.

TELEPHONES are already in use on many trolley lines and they are now proposed for the cars of the New York and Brooklyn Bridge as a means of preventing accidents, especially in foggy weather, such as that of Nov. 19, when two men were killed by the collision of two trains. Assistant Engineer Kingsley L. Martin, a son of Chief Engineer and Superintendent C. C. Martin, has been experimenting with the telephones on the cars, and has come to the conclusion that the idea is feasible. Mr. Martin will experiment hereafter with a metallic circuit, which he thinks will give much better results than a circuit grounded on the trucks of the cars.

The plan Mr. Martin expects to make perfect will keep the train dispatcher in constant communication with the conductors of all trains on the bridge, and make a collision almost an impossibility. The train dispatcher will sit in his office and will have fastened to his ear at all times a telephone receiver. This will leave him the free use of his hands with which to operate the bells, &c. In front of him will be a switchboard, with signal bells, and a long-distance transmitter. There will also be in front of him the starter's gong, engine-room signals, and call bells.

On the end of the trains will be placed a head telephone and transmitter. The transmitter will be arranged directly in front of the brake-wheel, so that the conductor may use the brake and talk through the transmitter at the same time. In case anything goes wrong, the conductor will simply have to speak into the transmitter and the train dispatcher, wearing the head telephone, will know instantly what is wrong, and will be able to communicate to the trains in the rear.

When the dispatcher wishes to talk to a conductor he will ring the bell, the conductor will pick up the receiver which will be at hand, and then the dispatcher will call the name of the trainman that he has in view, and the others will simply hang up their transmitters for future use.

The benefit of the telephone in foggy weather is apparent, and at such times, in order not to lose a second's time, the conductors will all wear head telephones, so that the train dispatcher will not have to ring. He will simply give his instructions through the transmitter, and every conductor at work will hear what he has to say.

Mr. Martin, in his experiments, has used the long-distance wall telephones, and the current was obtained from the electric trolley wires now in use. While the car was standing in the station, a communication was easily obtained, and when in motion conversation could be conducted on the way to New York.

TELEPHONE POLE RIGHTS IN DAYTON, O.

A special dispatch from Dayton of Dec. 22 says:—The Central Union Telephone Company received a severe blow here yesterday, when the Circuit Court decided that it had no right in the streets or alleys with its poles and wires, and issued an order of ouster. The company had a franchise for ten years, and neglected to have the franchise renewed. For two years it had no franchise, but no one molested or disputed its right to the streets until a rival company came here and applied for a franchise.

THE NEW PACIFIC CABLE PLANS.

With regard to the plans of the new Pacific Cable Co., already noted, ex-mayor Hewitt, one of the largest shareholders says:—"The Government of Hawaii has granted to Col. Spaulding, a well-known planter of the Hawaiian Island, a concession for a cable to the United States, with a subsidy of $40,000 a year. Col. Spaulding came to New York for the purpose of forming a company to lay the cable, but a subsidy of $40,000 a year is certainly inadequate to pay the interest on the outlay and expense for maintenance, which it is estimated will be about $800,000 a year. In the last Congress a bill was introduced and passed by the Senate, authorizing the President to contract for a cable to the Hawaiian Islands at a cost not to exceed three millions of dollars. The bill failed in the House, where it was thought that a corporation would be a better agency for securing a cable, because for commercial and general purposes Government ownership and general management are not desirable.

"Col. Spaulding's idea is to apply to the Government of the United States for a sufficient subsidy to warrant the laying of the cable and for its maintenance. As the enterprise is of great public and commercial importance, several prominent gentlemen have agreed to co-operate with Col. Spaulding and to furnish the money required, provided the subsidy is secured. Their object, however, is not to make any money out of the enterprise, and hence, in the bill which will be presented to Congress, provision is made that the United States Government may at any time

release itself from the subsidy by taking the cable from the company at the actual cost of construction.

"In other words, the object of these gentlemen is to secure to the United States the advantages of cable communication with the Hawaiian Islands, in the hope that the cable at some future time may be extended to Australia and China, with which countries we have large and growing commercial relations."

WESTERN UNION CONDUITS FOR KANSAS CITY, MO.

The Western Union Telegraph Company's Manager, at Kansas City, Mo., Mr. M. D. Wood, has asked that the public improvements committee of the lower house act on a separate ordinance introduced for the Western Union over a year ago.

The Western Union wires are concentrated in a small portion of the city and the company does not wish to build over two miles of conduit. It asks, however, that it be given a separate conduit. The substitute for the Western Union company's old conduit ordinance provides that the company can be compelled by the city to rent portions of its conduit to other telegraph companies, and reserve one duct for the city. Of the money derived from rentals, 10 per cent. is to go to the city, which is also to receive twenty cents a year for every yard of conduit as rental. There has never yet been offered to the council a valid reason why all electric wires of the same class should not use the same conduit. Separate manholes are given in some places, so that workmen of one company cannot disturb what belongs to another company.

PROBABLE SALE OF THE B. & O. WESTERN UNION STOCK.

When Mr. Jay Gould absorbed the Baltimore & Ohio Telegraph service, a large amount of Western Union stock was issued for the purchase. It is now said that there is a likelihood of the stock coming on the market, the condition of the B. & O. being said to require a realization upon the property, as it can use the money to advantage for extensions of its railway lines and the lifting of debt. Last week, the general uneasiness caused by Mr. Cleveland's Venezuelan pronunciamento, was added to by sharp declines in Western Union and Baltimore and Ohio. Officers of the latter company attributed the decline in its stock to a bear attack, but as there were only 1,870 shares traded this seems hardly probable. The stock broke from 40½ to 33, a net loss of 7½ points Being without support, the attempt of a few individual holders to liquidate in view of the very bearish rumors concerning the financial condition of the property, is quite sufficient explanation of the decline. Western Union's decline of 3⅝ points was accompanied by a rumor that the Baltimore and Ohio was marketing some of its holdings of 40,000 shares. Officers of the Baltimore and Ohio were emphatic in denying the rumor, adding that not a single share had been disposed of. At the same time, reports of an impending default by the Baltimore and Ohio were denied.

NEWS AND NOTES.

THE NATIONAL ELECTRICAL EXPOSITION.

Mr. Clarence E. Stump, who is so well known in the electrical field, has been appointed General Manager of the Electrical Exposition which is to be held in New York City, beginning May 4th and continuing until the first of June.

Numerous inquiries for information regarding space and other details are being daily received by the management, and a large number of prominent manufacturers have already closed contracts, while many additional firms have signified their intention to make extensive exhibits. The success of the enterprise is assured, and all indications point to the largest and most interesting display of electrical apparatus and supplies ever made in this country.

ELECTRICAL WORK AT PEORIA, ILL.

The directors of the Central Ry. Co. held an important meeting and decided to increase the capital stock from $600,000 to $750,000. The increase is to be divided pro rata among the stockholders if they so desire it. It has also been decided to issue bonds to the amount of $750,000, of which $500,000 will be disposed of immediately and the remainder sold as occasion may require for the betterment of the road.

The system is now bonded to the extent of $300,000, the first mortgage bonds being for $200,000 and the second for $100,000, both bearing 5 per cent. interest.

The new bonds will draw 6 per cent. interest and it is thought that the stockholders will take them pro rata. The first and second mortgages can be taken up at any time and it is the purpose to take them up and wipe out the old indebtedness and leave the balance for improvements.

The old Fort Clarke power house has been abandoned and the boilers and machinery removed to the Central Ry. Co.'s power house, which is now furnishing power for all the lines.

The Board of Park Commissioners have decided to put an electric light plant of their own in Glen Oak Park, as they find it will be much cheaper than to rent the lights from the Péoria General Electric Co.

MATERIAL FOR INCANDESCENT CONDUCTORS.

A recent invention of Dr. Ludwig K. Böhm, of New York, N. Y., has for its object the improvement of filaments for incandescent lamps. Heretofore the material generally used for filaments has been carbon, usually of the highest degree of purity obtainable. In Dr. Böhm's invention, the carbon instead of being pure is combined with calcium. The resultant carbide of calcium has sufficient electrical conductivity to render it a suitable and efficient material for incandescent conductors, and furthermore possesses the advantage of higher specific resistance than pure carbon.

HONEY IN AN ELECTRIC LIGHT GLOBE.

For some time the electric light globe in Monument Square, New Brunswick, N. J., has been in disuse, and on Dec. 24, Frank Boudinot, a lineman, went to repair it. When he got up to remove the globe he was attacked by a swarm of bees that had taken possession of the globe as a hive, and was severly stung before he could escape. Afterward the bees were smoked out, and the globe was found to be more than half full of honey.

CLEAN RECORDS FOR MOTORMEN.

One year ago the Steinway Trolley Company of Long Island City, posted a notice stating that any man running his car for one year without an accident would receive $25 as a Christmas present. Dec. 24 was the time for making the presents, and ninety-eight men received the full amount. There were ninety-four men who had not been in the employ of the company for a year, and they recived amounts in proportion to their term of service. It took over $4,000 to make the presents, but the officers of the company feel fully repaid for their gifts to their employees.

HOLLIS PREFERS THE CURFEW.

The other day a proposal was made at a parish meeting for the lighting of the village of Godshill, Isle of Wight, with eight lamps, which, it seems, could be maintained at the modest cost of a halfpenny rate once every three years. Up rose a farmer named Hollis to oppose the revolutionary scheme. To the mind of this worthy English rustic, its authors were "wanting to turn night into day." "It would set a bad example to the young," he continued, "keeping them out all hours of the night. What they ought to do was to set a good example by going to bed early and getting up early, and he would like to hear the curfew rung again."

THE CHRISTMAS STORM IN INDIANAPOLIS.

A special dispatch of Dec. 26 from Indianapolis, Ind., says: A blizzard has prevailed in this city from early this morning. The streets at noon were almost impassible, and the telephone and electric light wires were in a tangled mass. Not a telephone is in working order. One horse was killed, and several persons rendered insensible by coming in contact with "live" electric wires. Gangs of men are at work trying to get the wires off the streets, but the storm is increasing in force, and work progresses slowly.

ELECTRICAL PROVIDENCE.

The Providence, R. I., *Telegram* has just issued a very handsome Christmas week edition. Part of its space is devoted to an account of the leading industries of the city, and we are glad to note that the American Electrical Works and the Armington & Sims Engine Co. come in for very full treatment, as they deserve. The growth of such notable industries has done much to assist in the promotion of the prosperity of Providence, as well as to render electrical work safer and more efficient. There are illustrated articles also on the Providence Telephone Exchange and the Pawtucket and Narragansett Electric Light Companies, and the Union Traction Company. The *Telegram* is to be congratulated upon its success and upon the energy that characterizes its management.

THE VANITY OF CONGRESSMEN.

Some of the Congressmen do not like the new electric method of calling pages by pressing a button; the old way of clapping hands attracts more attention from the galleries.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED DEC. 17, 1895.

Accumulators :—

Process for Renovating Storage Batteries, J. Trowbridge, Cambridge, Mass., 551,565. Filed Oct. 1, 1895.
To reduce the sulphate the negatives are temporarily removed and zinc plates substituted.

Conductors, Conduits and Insulators :—

Cable Hanger, S. S. Leonard, Chicago, Ill., 551,504. Filed Aug. 8, 1895.

Dynamos and Motors :—

Electric Motor, M. J. Wightman and O. C. G. Urban, Cleveland, O., 551,567. Filed May 16, 1895.
An electric motor having a pole piece constructed in two sections; the rearward or outer section is removable whereby the inner section is capable of being moved outwardly or backwardly from the armature.
Dynamo Electric Machine, A. B. Blackburn and W. Buchanan, Wolverhampton, Eng., 551,712. Filed Oct. 1, 1895.
Details relating to construction of laminated fields of a self exciting alternating machine of the inductor type.

Electrometallurgy :—

Apparatus for Manufacturing White Lead by Electrolysis, A. B. Browne, Cambridge, and E. D. Chaplin, Natick, Mass., 551,361. Filed July 2, 1894.
Details of construction for electrolyzing lead in nitrate of soda.
Art of Producing Carbide of Calcium, W. C. Clarke, New York, 551,461. Filed Apl. 29, 1895.
Arranged so that at the end of the process the body of carbide is surrounded by an undecomposed mass of the mixture of lime and carbon.
Electrolytic Process of Obtaining Precious Metals, L. Pelatan, Paris, France, and F. Clerici, Milan, Italy, 551,648. Filed June 25, 1895.
The cathodes rest on the bottom of the vat. The anodes are revolving cylinders with anode plates between each group.

Lamps and Appurtenances :—

Incandescent Electric Lamp, C. A. Beal, Abington, Mass., 551,357. Filed Feb. 28, 1895.
Relates to the construction of socket for a double filament lamp.
Magnetic Electric Lamp Holder, M. H. Collom, Denver, Colo., 551,364. Filed June 12, 1895.
A magnet is attached to the socket so that the lamp can be suspended from any part of an iron structure.
Electric Light, D. Misell, New York, 551,394. Filed Apl. 5, 1895.
A table lamp with battery, and mechanism for breaking the circuit intermittently.

Measurement :—

Electric Meter, T. Duncan, Ft. Wayne, Ind., 551,486. Filed July 11, 1895.
An improved induction motor meter in which the losses due to the series coil is reduced, the torque increased and the humming noise avoided.

Miscellaneous :—

Heat Regulator, W. W. Wilcox, Westerly, R. I., 551,497. Filed April 6, 1895.
A damper regulator operated by a thermostat. The movements of the damper are effected by water acting upon a tipping pan, and the flow is controlled by a valve operated by the thermostat and a magnet in its circuit.
Electric Lighter, H. E. Rider and J. Hencken, New York, 551,451. Filed Nov. 10, 1894.
A torch is lighted by a spark from induction coils, by the act of removing the torch.
Electric Lock, P. and J. A. Meyer, Newark, N. J., 551,682. Filed Feb. 23, 1895.

Railways and Appliances :—

Closed Conduit Electric Railway System, F. C. Esmond, Brooklyn, N. Y., 551,584. Filed April 12, 1895.
Details referring to a system in which the live conductor is switched into the car current by electro-magnetic switches as the car passes over each section.
Closed Conduit Railway System, F. C. Esmond, Brooklyn, N. Y., 551,585. Filed Apl. 12, 1895.
Similar above.
Closed Conduit Electric Railway System, F. C. Esmond, Brooklyn, N. Y., 551,586. Filed Apl. 26, 1895.
Similar to above.
Closed Conduit System for Electric Railways, F. E. Esmond, Brooklyn, N. Y., 551,587. Filed Sept. 11, 1895.
Similar to above.
Electric Railway, R. M. Hunter, Philadelphia, Pa., 551,587. Filed Feb. 23, 1887.
Relates to a construction in which the armature is mounted directly on the axle.
Electric Railway Motor Shield, I. F. Baker, W. R. McLain, Lynn, Mass., 551,664. Filed Nov. 25, 1889.
A shield interposed between the motor and the ground for the purpose of intercepting bits of magnetic material attracted from the ground.
Transmission of Electricity to Moving Cars, T. Nesom, Indianapolis, Ind., 551,784. Filed Sept. 21, 1894.
A surface conduit system in which contact is made by magnets attracting the conductor.

Regulation :—

Means for Operating and Regulating Speed of Electric Motors, R. Eickemeyer, Yonkers, N. Y., 551,371. Filed Dec. 31, 1892.
The independent exciting current is generated by a governing dynamo, which is driven by a reversible motor in either direction, and a switching mechanism provides for not only controlling the motor circuit but also for appropriately controlling separate divisions of the field in the governing dynamo, and also controlling its armature circuit, which includes the governing field coils in the motor.
Controlling Electric Motors, D. Mason, Schenectady, N. Y., 551,470. Filed Apl. 22, 1892.
A method of connecting several motors, using one as a starter.
Electric Motor, F. E. Herdman, Winnetka, Ill., 551,633. Filed Aug. 6, 1894.
Device for increasing or decreasing the field current.
Mechanism for Admission and Regulation of Currents to Motors, F. E. Herdman, Winnetka, Ill., 551,634. Filed Mch. 29, 1895.
Similar to above.
Mechanism for Admission of Currents to Motors and Regulation of Currents in Same, F. E. Herdman, Winnetka, Ill., 551,685. Filed June 28, 1895.
Similar to above.
System for Regulating Effective Tension of Electrical Circuits, H. O. W. J. Breul, Berlin, Germany, 551,743. Filed Nov. 17, 1893.
Means for increasing or decreasing the electromotive force impressed upon the several feeding conductors, and a device responsive to the reversal of current in a feeding conductor.

Switches, Cut-Outs, etc.:—

Strong Current Protector, A. L. Joynes, Paducah, Ky., 551,388. Filed Jan. 9, 1895.
The device opens the line wire and ground return in telephone exchanges.

Telegraphs :—

Teletyper, C. Spiro, New York, 551,515. Filed Aug. 14, 1895.
The improvement is in the form of an attachment, which may be readily applied to any type-writers already in use.

Telephones :—

Automatic Telephone Exchange System, W. F. Lounsbury, Oswego, N. Y., 551,391. Filed April 23, 1895.
The connections are effected by magnets which shift from one subscriber to the other.
Holder for Telephone Receivers, F. W. Martland, Fall River, Mass., 551,551. Filed June 10, 1895.
Telephone Transmitter, T. Grissinger, Mechanicsburg, Pa., 551,674. Filed Oct. 18, 1894.
A granulated carbon transmitter provided with a vibrator to prevent the granules from packing.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED DEC. 24, 1895.

Alarms and Signals :—

Electric Latch Apparatus for Semi-Automatic Operation of Railroad Signals, H. C. Barnes, and W. W. Slater, Oakland, Cal., 551,942. Filed March 21, 1895.
Electric Signal, E. M. Phelps and A. T. Sampson, Lynn, Mass., 551,998. Filed Oct. 8, 1891.
The combination of a trolley wire and electromagnet in circuit therewith, an armature arranged to be moved within the field of the magnet by the trolley and to close the circuit through the magnet to hold it attracted, a signal in circuit with the magnet and a circuit breaker for breaking the circuit.
Electrical Switch Operating and Signal Apparatus, J. Dutrey, New Orleans, La., 552,053. Filed May 25, 1895.
Circuit Closer and Breaker, J. R. Farmer, St. Louis, Mo., 552,057. Filed Jan. 25, 1895.
Relates to a means for introducing a current of electricity through a lamp, said lamp adapted to serve as a danger or other signal on electric car lines, and operated by the trolley-wheel of a passing car.

Conductors, Conduits and Insulators :—

Art of Making Armored or Compound Tubes, E. T. Greenfield, New York, 552,059. Filed May 16, 1895.
Armored Tube of Conduit, E. T. Greenfield, New York, 552,060. Filed May 16, 1895.
Above two patents describe method and apparatus for manufacturing insulated iron armored conduit. The inner treated paper tube is inserted in the exterior heated iron pipe with a cementing material between. The iron pipe on cooling contracts and grips the interior tube.

Distribution :—

System of Electrical Distribution, T. F. Mullaney, Worcester, Mass., 551,781. Filed Sept. 24, 1895.
When a ground is indicated, on the positive side, and there is already a ground on the negative side, the circuits can be so changed by means of switches that the grounds will both be on the same side of the system; and vice versa.
Converting Simple into Polyphase Alternating Currents, C. S. Bradley, Avon, N. Y., 551,809. Filed June 11, 1892.
Relates to the system described in the paper on "Phasing Transformers." See THE ELECTRICAL ENGINEER, Oct. 2, 1895.

Dynamos and Motors :—

Alternating Current Motor, C. S. Bradley, Avon, N. Y., 551,810. Filed Sept. 12, 1893.
Relates to a self starting alternating motor described by same inventor in THE ELECTRICAL ENGINEER Oct 2, 1895, page 324.
Commutator Brush, C. C. Dusenbury, Lake Mahopac, N. Y., 551,856. Filed June 10, 1895.
The arms are made integral with the end frame or permanently connected thereto.
Alternating Current Machine, M. Hutin & M. Leblanc, Paris, France, 551,-868. Filed May 1, 1895.
Improvement upon a like invention, patent No. 539,272. A synchronous alternating current motor of low resistance and self induction and having a constant field of force, and an asynchronous alternating current motor of comparatively high self induction, both simultaneously fed from the same alternating source and having their rotating elements mechanically coupled.

Lamps and Appurtenances:—

Electric Arc Lamp, E. Thomson and C. E. Harthan, Swampscott, Mass., 551,-799. Filed May 9, 1895.
Improvements relating to the manipulation of the carbons.
Material for Incandescent Conductors, L. K. Böhm, New York, 552,086. Filed Nov. 5, 1891.
Employs carbide of calcium.

Measurement :—

Station Potential Indicator, R. D. Mershon, Pittsburg, Pa., 551,982. Filed Apl. 29, 1895.
A station potential indicator for alternating current systems comprising a local circuit in which the inductive and non-inductive counter electromotive forces and the impressed electromotive force of the main line are reproduced in miniature, and a voltmeter for indicating the value of the resultant of these electromotive forces.

Miscellaneous :—

Electrogalvanic Belt, S. J. Spalding, Canton, O., 551,795. Filed May 9, 1895.
Electrical Eye Cup, T. B. Wilcox, Newark, N. J., 551,880. Filed Jan. 10, 1895.
A cup for application to the eye or other part of the body.
Art of Recording and Reproducing Impulses, W. H. Cooley, Brockport, N. Y., 551,946. Filed Apl. 16, 1889.
The object of the invention is recording of impulses capable of actuating a diaphragm and recording stylus, or equivalent device, in such a manner that such impulses may be reproduced from such record.
Automatic Temperature Regulating Apparatus, C. L. Fortier, Milwaukee, Wis., 551,951. Filed May 8, 1893.
Consists essentially of the combination, with means for operating a heat

controlling valve or damper including an electromagnet and electric generator connected by a circuit provided with a thermostat, of a motor arranged to operate said generator intermittently and automatically at stated intervals.
Thermostatic Regulating Device, C. A. Hale, Cleveland, O., 551,959. Filed Jan. 8, 1894.

Motor Regulation and Control;—

Electrically Operated Elevator, F. B. Corey, Boston, Mass., 551,757. Filed May 13, 1895.
The movement of the elevator may be controlled from several points either within or without the car, by means of simple switches or push buttons.
Mechanism for Operating Elevator Controlling Mechanism, F. E. Herdman, Winnetka, Ill., 551,820. Filed July 10, 1895.
Consists in operating the elevator controlling mechanism by means of an auxiliary motor.

Railways and Appliances:—

Electric Railway Train Signaling, W. S. Greene, Covington, Ky., 551,930. Filed Sept. 3, 1895.
Relates to a form of coupling for connection between cars.
Pedo-Electric Trolley, R. T. Oney, Charleston, W. Va., 551,996. Filed Mch. 27, 1895.
For description see page 16, this issue.
Underground Current Supply for Electric Railways, A. Rast, Nuremburg, Germany, 552,001. Filed Mch. 29, 1894.
Contact is made with the working conductors by electromagnetic switches enclosed in watertight boxes, and actuated by an attracting magnet carried on the car.

Switches, Cut-Outs, Lightning Arresters, etc.:—

Lightning Arrester, W. B. Potter, Schenectady, N. Y., 551,786. Filed Aug. 31, 1895.
Consists in an arrester provided with a plurality of spark-gaps arranged in series. Each of the spark-gaps is placed in an insulating-chute and separated from the others.

Telegraphs:—

Electric Telegraph, W. H. Cooley, Brockport, N. Y., 551,947. Filed March 23, 1889.
At any transmitting station, the operator, by pressing any one of a certain number of keys, can energize the corresponding electro-magnet at the receiving station. Each one of such electro-magnets at the receiving station can of course be used to actuate a different key of a typewriter or other similar instrument.
Electric Telegraph, W. H. Cooley, Brockport, N. Y., 551,948. Filed April 18, 1893.
Object of the invention is the lengthening of the time allowed at the receiving station for the printing of a character without diminishing the speed of transmission and receiving.

LEGAL NOTES.

THE RIGHT TO FIX TELEPHONE RATES.

S. STERNE VS. MET. TEL. & TEL. CO.

THE temporary injunction which Simon Sterne obtained a year ago preventing the New York Metropolitan Telephone and Telegraph Company from removing the telephone from his office at 56 Beaver street has been made permanent by Justice Ingraham of the Supreme Court, pending the action brought by Sterne for the same relief. He is required to give a bond to secure the company from loss of rents and damage, if it should ultimately be decided in the action that he was not entitled to the injunction.

The case is a test case, and turned mainly on the question whether the company has the right to fix rates arbitrarily, or whether it is a common carrier which must take business at such rates as the courts, in the absence of legislative direction, shall hold to be reasonable. Until October, 1894, Sterne had a telephone service at $125 a year, but in that month he and other subscribers were notified that owing to improvements in the service they must call and make new contracts for $240 a year. It was urged that the underground wiring had cost the company $3,000,000, and that it had resulted in better service. The company contended that its new rates were reasonable, and that in any event the courts could not say what it should charge its own customers, as it was a matter of private contract.

Mr. Sterne disregarded the threats of the company to remove his old telephone unless he signed a contract for the higher rates. He said that his old telephone was good enough for him. When the company finally set a day for him to sign or have the telephone removed, he procured the temporary injunction from Justice O'Brien. Owing to the importance of the case it was argued very fully last February, and Justice Ingraham had since then reserved decision, having to wait a large part of the time for briefs of the counsel.

Mr. Sterne submitted affidavits the aim of which was to show that excellent service was given in most of the large cities of Europe for from $100 to $125 a year, and that the defendant made large profits under the old rates.

An affidavit of President Charles P. Cutler stated that the service in London and Berlin was much inferior to that in this city.

Justice Ingraham said on the argument that he had no doubt that the Legislature had the right to supervise the rates charged, but the right of the Court in the matter was uncertain. In the decision handed down last week Justice Ingraham says:

"There can be no doubt whatever but that the Legislature could regulate the business of this defendant. I think it is clear that at common law, in the absence of legislative enactment, a common carrier is bound to furnish transportation to the public for a reasonable charge, and the courts, upon a proper application made, may determine in each case what is the proper and reasonable compensation to be paid to the corporation and compel the corporation to furnish transportation on the payment of such reasonable compensation. I am inclined to think that this duty of the courts extends to a business carried on under the authority of law which is in its nature a public business 'affected with a public interest,' and that the transmission of intelligence by electricity is a business of such a public character that it is to be exercised under public control.

"If this view of the law is correct, the question then arises as to whether or not the rate charged by the defendant for the services rendered is a reasonable charge under all the circumstances. I do not think that that question can be fairly determined upon affidavits. A much more satisfactory method of determining questions of this character is upon the trial of the issues where the witnesses can be cross-examined. The defendant should, however, be placed in such a position that if the plaintiff fails to establish upon the trial that he is entitled to a judgment he will pay upon such final determination the rate fixed by them."

DECISION IN CONNECTICUT ON ADJACENT LANDOWNERS RIGHTS.

In the Superior Court of Hartford County, Connecticut, Judge Ralph Wheeler has handed down a decision in which he says that a real estate owner claiming damages against a trolley company must prove unreasonable occupation of land by such corporation and must prove also for himself special and not general damages. Should this case be appealed it will raise in the Supreme Court of the state the whole question of the right of adjacent landowners to compensation from trolley companies.

The same question is to be raised soon in the Superior Court of New Haven in a case of the New Haven Steam Railroad Company against the Fairhaven and Westville Trolley Company, but Judge Wheeler's decision apparently anticipates it and is the first ruling on the subject in a lower court of the state.

SOCIETY AND CLUB NOTES.

HENRY ELECTRICAL CLUB.

AT the meeting of the Henry Electrical Club, on Dec. 20, Mr. Geo. F. Sever read a paper on "Testing of Dynamos and Motors."

He treated dynamo and motor testing as the determination of their electrical and commercial efficiency, and showed how the measure of the efficiency depended on the values of the various losses in the machines. These were divided as follows: Friction of bearings; brush friction; resistance of the air to the motion of the armature; Foucault currents; hysteresis in the armature iron; and the C^2R loss in armature and field coils.

In the case of the dynamo, the commercial efficiency was equal to the E. M. F. multiplied by the current delivered, divided by the total power supplied at the belt. In the motor it was the mechanical power delivered at the belt, divided by the product of the E. M. F. and the current supplied to the machine. The electrical efficiency was the counter E. M. F. divided by the impressed E. M. F.

With the aid of an extensive series of lantern views Mr. Sever described the steam-engine indicator; Emerson power scale; Weber power transmission dynamometer; Brackett cradle dynamometer, rope and Prony brakes, or absorption dynamometers; and electrical methods of the Hopkinson and allied types.

On Dec. 27 no regular paper was read. The evening was devoted to a general discussion of the subjects taken up in the course of the quarter.

REPORTS OF COMPANIES.

OKONITE CO.

The annual general meeting of the Okonite Company, Limited, was held at the office of the Company, 13 Park Row, New York City, on Wednesday, December 18, 1895. A number of matters of interest to the Company were discussed. The accounts were also presented and passed.

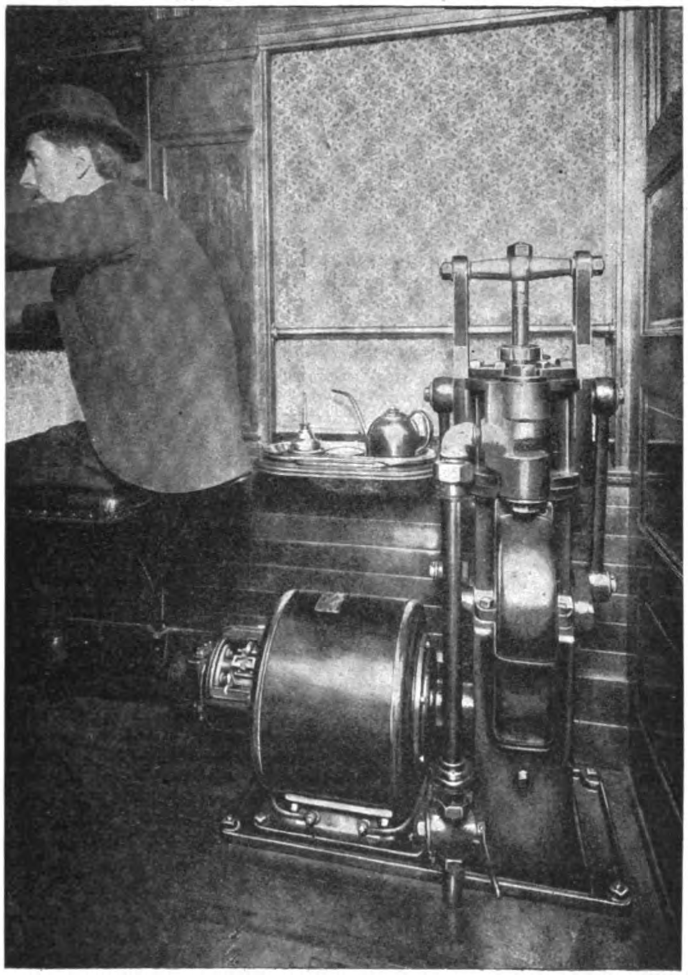
THE WESTINGHOUSE ELECTRIC & MFG. CO. have declared a quarterly dividend of 1¾ per cent. on the preferred stock, payable Jan. 2.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

STOREY MOTORS ON THE CHICAGO METROPOLITAN.

Without doubt one of the finest equipments of its kind that can be found is that of the Metropolitan West Side Elevated Railroad of Chicago, Ill. Elevated railroads in many respects far exceed all other means of transportation within city limits,—yet when operated by steam there are numerous features about them that are objectionable ;—thus the public are quick to appreciate a road which is operated by electricity. A very important feature in the smooth operation of a road lies in the system of braking. In this respect as in several others the equipment on the above system is second to none and this one feature presents several points of interest. The air-compressors, which were furnished by the New York Air-Brake Co., are placed in the cab set apart for the use of the motorman. These compressors are operated by motors directly connected and as will be seen by the accompanying illustration the equipment is very compact. The motors are



STOREY MOTOR ON THE CHICAGO METROPOLITAN ELEVATED.

completely enclosed, are dust and moisture proof, and were furnished by the Storey Motor and Tool Co. of Philadelphia, who also supply equipments of a similar kind for lighter work and for use on ordinary trolley cars as well as motors for all kinds of pneumatic equipments.

These machines run at a speed of 650 revolutions at 450 volts and develop 3½ H. P. They are constructed to stand an increase of voltage to 700 and occupy a space over all of 15⅛ by 30½". They weigh 400 pounds and there are at present 61 of them in operation.

It would be an agreeable surprise for some of our New York friends if they could take a ride on this road ;—they would surely be astonished to see the difference between an elevated road operated by electricity and one where steam is the motive power.

BARNEGAT LIGHTHOUSE, New Jersey, is to have one of the 3,500,000 C. P. search lights shown at the World's Fair.

THE "ENTERPRISE" LAMP GUARD.

THE incandescent lamp guard shown herewith, called the "Enterprise" and put on the market by Edward Darby & Sons, of the Pennsylvania Wire Works, Philadelphia, is, as will be seen, a very neat and handy contrivance. It needs no holder to fasten it to the socket, and constitutes an attachment easy to manipulate. Opening in the middle, it permits prompt and easy renewal of lamps. The wire is tinned, and the guard presents a light and graceful appearance.

GENERAL ELECTRIC BUSINESS.

THE Boston News Bureau says :—The General Electric Co. is doing a little better than $1,000,000 of gross business per month, and is striving for a fair manufacturing profit, but is not getting it on all lines. It is probable that the gross business for the fiscal year will foot up slightly above $13,000,000 which at prevailing prices means a very large tonnage of electric goods. There ought to be $2,500,000 manufacturing profit in this, but it is doubtful if such will be found when inventories are taken at the close of the year. However, it is expected that 8 per cent. will have been earned upon the common stock this year besides interest and full dividend on the preferred. Nothing, however, will be done this year toward the payment of any dividend on the preferred stock. They will be allowed to accumulate thereon for some time. It is felt that the matter can be better adjusted when the company has clearer views as to dividend policies than at present.

APPARATUS WANTED.

Mr. Ernest Gonzenbach, E. E., Supt., Electric Light & Power Co., Barton, Vt., writes us :

I have two or three contracts for isolated plants on hand and am in the market for direct current dynamos up to 60 kilowatt, also one new or second-hand 15-light arc machine and lamps. I would invite quotations with lowest net prices from your advertisers on the above apparatus, as well as on induction motors and wiring material.

BAXTER MOTOR CO.

The sale of the Baxter Electric Motor Company property to Benjamin Deford for $25,000 was finally ratified last week, by Judge Wickes in Circuit Court No. 2, Baltimore, the exceptions to the ratification being dismissed. Mr. Deford purchased the property in the interest of certain bondholders. It was claimed in the exceptions that the price was inadequate.

SIEMENS & HALSKE ELECTRIC CO.

The Siemens & Halske Electric Company of America have opened new offices in the American Surety Building, 100 Broadway, New York. This will be the General Eastern Office, and will be in charge of C. E. Yerkes, Vice-President.

F. N. Armour, recently of the Chicago Office, will be the General Sales Agent.

Chas. D. Shain still retains the Agency for New York City and the immediate vicinity.

THE WALKER CO. OF CLEVELAND.

The Walker Company, of Cleveland, has been incorporated under the laws of New Jersey, to manufacture electric generators and motors and other kinds of electrical apparatus. The capital stock is $2,500,000. John Ludwig, of Brooklyn ; Charles N. King and Martin W. Dixon, of Jersey City, are the incorporators.

DECORATIONS OF A PHILADELPHIA WEDDING FEAST.

MR. F. B. MASSEY, of Francis Bros. & Jellett, Incorp., did some elaborate special decorative work at the Mercantile Club, Philadelphia, recently for a wedding banquet. He used some 600 miniature lamps of various colors, and about 200 16-candle power colored lamps. The decoration comprised the placing of various colored lamps on the columns through the room, with banks of white lamps in side brackets along the sides. The tables were in the form of a hollow square, broken at either end ; with a massive heart-shaped table in the centre of the square. Decorations for the long tables were umbrella-shaped wire stands, having 18 miniature lamps each, and having in all some twenty stands. The lamps on each stand were different in color. The heart-shaped table was decorated with varied colors of stalactite lamps of

entirely new design. In the centre of the heart upon a raised platform, was a lion made from yellow chrysanthemums. The eyes of this animal were two red miniature lamps; around the lion was a massive bank of white chrysanthemums. Under the chrysanthemums were some 40 or 50 16-candle power lamps. The effect of these various colors showing through the flowers was very beautiful.

ADVERTISERS' HINTS.

A. O. SCHOONMAKER is again advertising his commutator segments.

THE "ENTERPRISE" LAMP GUARD requires no holder to fasten it to the socket. It is made of tinned wire by Edward Darby & Sons, Philadelphia.

GLASS AND PORCELAIN insulators, cleats, tubes, knobs, etc., are stocked in great variety and quantity by the Electric Appliance Co. who are quoting manufacturer's prices on all orders.

THE STANDARD AIR-BRAKE Co. claim to have been the first in the world to build air brakes for street railway service and to have received the only award for such brakes at the Columbian Exposition.

THE MICA INSULATOR Co. in their "ad" this week, publish some very interesting information regarding the electrical equipment of the "St. Louis" and the "St. Paul," the new steamers of the American Line. Micanite was the insulation used on all the dynamos and motors.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING Co. begin the year by wishing all their friends a happy one and suggest that to use well insulated wires and cables means to avoid trouble and expense. They mention the Habirshaw products as meeting this requirement.

THE WESTERN ELECTRIC Co. call attention to a combination bridge, rheostat and galvanometer. This instrument consists of a sensitive detector galvanometer and an improved form of Wheatstone bridge, with rheostat, all arranged in one case so as to form a complete and perfect portable apparatus for measuring resistance.

NEW YORK NOTES.

THE J. E. PUTNAM Co. has been formed at Rochester, N. Y., to manufacture electrical appliances. The capital is $15,000. The directors are S. A. Ellis, J. E. Putnam and W. B. Hale.

A HUGE CHRISTMAS TREE, standing 40 feet high was one of the holiday sights in the store of Hilton & Hughes. There were 600 incandescent lamps on the tree and 400 in a bell and star above it.

MR. CHARLES COOPER, once so well known in electric lighting circles in Brooklyn, is returning to the field and is one of the prime movers in the new Kings County Electric Light Co., which is bidding at 32 cents a night for city arcs.

BROOKLYN EDISON.—The Edison Electric Illuminating Company of Brooklyn reports a net income for the month of November of $36,960, an increase of $6,831 over the corresponding period last year, and for eleven months of $314,878, an increase of $32,-999.

MR. L. J. HIRT, assistant chief engineer of the Metropolitan Traction Co., gave a lecture recently to about two hundred gripmen, on the mechanism employed on the road. President Vreeland introduced the speaker, and Supt. Newell of the Twenty-third street road presided. Mr. Hirt is not less well acquainted with the Metropolitan conduit trolley system than with the cable, and may presently give a talk on that.

MAGUIRE & BACKUS, LTD., of New York city, has been incorporated to purchase and sell or otherwise dispose of patents, licenses, contract rights, powers, privileges, etc., relating to inventions, machines and processes, electrical or otherwise. The capital is $250,000; and the Directors are Wm. H. Paxton, Jr., Walter B. Howe, M. C. Fleming, Dr. H. Clark and A. E. Miller, of New York.

MR. RALPH L. SHAINWALD, president of the Standard Paint Co., of New York, has just returned from an extensive trip in Europe, and says that he was much gratified to find that the famous P. & B. paint was just about as well known in Europe as in the United States. Even as far East as Egypt the magic initials are quite familiar, and the streets of Cairo are no strangers to the great and popular United States product.

THE NEW YORK CARBIDE AND ACETYLENE COMPANY has been formed to manufacture and sell gas-producing materials and acetylene gas and to distribute and deal in gas apparatus in Millbrook, Dutchess County; capital $7,000,000, divided into 70,000 shares, and the company begins business with its full capital; Directors—E. C. Benedict, Anthony N. Brady, Edwin N. Dickerson, J. Bertschmann, Charles F. Dietrich, Walton Ferguson, John Fox, R. Somers Hayes, Erasmus J. Jersnanowski, Frederick P. Olcott, Arthur B. Proal, John Sloane and Samuel Thorne of New York City. Julius J. Suckert of New York City subscribes for 69,988 shares of the capital stock of the company.

MR. W. R. BRIXEY, proprietor of Day's Kerite wires and cables, has very kindly complimented the editorial staff of THE ELECTRICAL ENGINEER with a Christmas present in the shape of a handsome Waterman stylographic pen. Such generous thoughtfulness is deeply appreciated, and it is hoped that many an occasion will present itself through the coming years to use the pen in extolling the virtues and victories of the donor's manufactures.

WESTERN NOTES.

GRANVILLE, O.—The Denison University have recently added to their electric light plant a 70 H. P. Ball engine, from the Ball Engine Co. of Erie, direct connected to a Thresher dynamo.

THE WESTINGHOUSE Co., through Mr. George Evans, has been looking for sites for a factory in the neighborhood of Toronto, Ont.

THE ELLIPTICAL CARBON Co. has been organized in Chicago by Fred DeLand, D. T. Foley and F. E. Drake with a capital stock of $100,000.

INSURANCE INSPECTION in Iowa of 890 risks showed 2,045 defects and 2,840 requests for improvements. Mr. W. C. Stewart, electrical inspector of the Iowa Alliance of Insurance Companies is making a complete canvass of the State.

MR. MARCELLUS HOPKINS, receiver of the Alley Elevated road in Chicago, says that the service costs $175 per day more with steam locomotives than it would with electric. "This is not a question of theory but has been fully demonstrated."

THE KANSAS CITY COMMERCIAL CLUB has approved a committee report strongly favoring underground wires, each company to lay its own conduits under exclusive control, but high voltage wires not to be buried.

"THE DANCING GIRL" of Chicago, graces with her beauty and agility the announcement of the Metropolitan Electric Co., who wish to intimate in this way the excellence of their goods and the celerity with which orders are executed.

THE AMERICAN ELEC. MFG. Co., St. Louis, have issued a 4-page circular as to the merits of their various incandescent lamps. Mr. A. L. Reinmann, formerly of the Sawyer-Man Co., is now their superintendent of factory, who is introducing many improvements he has effected in the last two years.

MR. THOS. I. STACEY, Secretary and Treasurer of the Electric Appliance Co., Chicago, has recently returned from a six weeks' visit to the South. Mr. Stacey was very pleased with his trip, and reports that the prospects for good times were very apparent in all the places he visited.

THE GATES ELECTRIC MANUFACTURING Co., of Chicago are making a specialty of direct connected dynamos in the smaller sizes particularly, the demand for which has not hitherto been supplied. They make dynamos from 5 K. W. and 400 revolutions upwards for connection to the engine without couplings or other space taking devices. The armature of large diameter is mounted directly on the engine shaft. The Gates dynamos are highly spoken of for their finish and smooth operation. They are now building a line of small multipolar motors and dynamos for belting.

THE SUNBEAM INCANDESCENT LAMP Co., Chicago, have recently commenced the manufacture of 2 C. P., 10 watt, and 4 C. P., 20 watt, incandescent lamps. These lamps have a small round bulb and are fitted with regular standard sockets. It is stated that the Sunbeam is the first lamp company to make lamps of such low candle power and wattage that can be connected in multiple. The principal use for these lamps will be in sign and decorative work. In sign work especially a lamp of low candle power is preferable, even without considering the saving in energy, as with the glow of the small incandescent lamp the sign is clearer than with the glare of the larger lamp.

NEW ENGLAND NOTES.

MR. G. D. BURTON, inventor and electrician, has filed a petition in insolvency in Boston. He owes $115,000 but holds assets of enormous nominal value, though in many cases of highly problematical future.

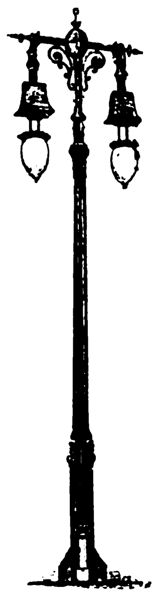
THE EDISON ELECTRIC ILLUMINATING CO. OF NEW YORK.

BY

Jos. Wetzler.

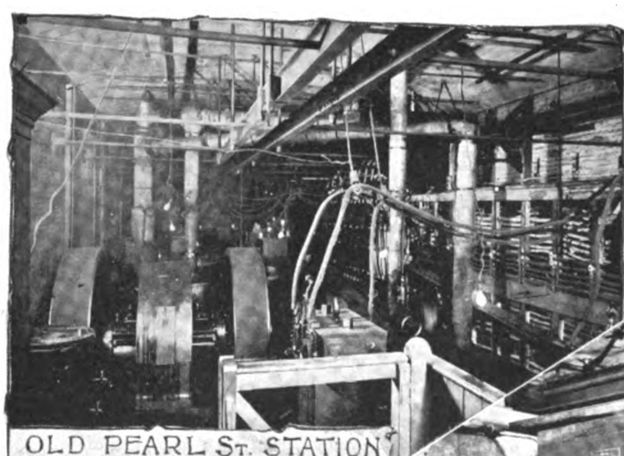
HISTORICAL.



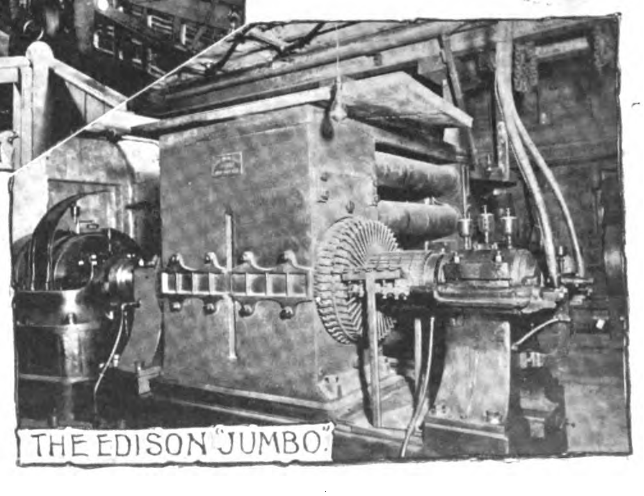
5th Ave Arc Lamp Post, Edison-Bowker System.

THE history and growth of an organization which stands as the pioneer of one of the greatest of modern industries, has not merely a value viewed from the academic standpoint, but carries with it lessons of practical import; and the more so when that history is one of continuous progress both technically and commercially. Perhaps no more conspicuous example of this kind could be found than that exhibited in the record of The Edison Electric Illuminating Co., of New York, which from its inception has been in the vanguard of progress in everything relating to low-tension generating apparatus and underground electric distribution; which has, at no small cost necessarily done much of the experimental work which has accrued to the benefit of all electric companies, and which remains the largest electric light and power supply corporation in the world.

Mr. Edison had barely finished his historical experiments when enterprising capitalists decided to introduce the new light in New York City. They proceeded at once to carry out their designs by the purchase in May, 1881, of two buildings on Pearl St., near Fulton, and shortly after began the laying of underground tubing and the wiring of houses. The conductors consisted of the familiar, but now obsolete "half-moon," type, made to conform to the outline of the iron tubing, and its installation occupied the personal attention of Mr. Edison, who for months frequently worked in the trenches and whose bed often consisted of a pile of tubing with a few overcoats thrown over it in the old construction office in Ann St. At the same time the construction of the—for those days—mammoth Edison "Jumbos" was proceeding apace, so that on July 5, 1882, the dynamos were run for testing purposes, and on Sept. 4, 1882, the Pearl St. station was regularly started with six Jumbo Edison steam dynamos of 125 H. P. each, direct coupled to Porter-Allen engines, lighting during the first month 85 houses, wired for 2,323 lamps.



OLD PEARL ST. STATION



THE EDISON "JUMBO."

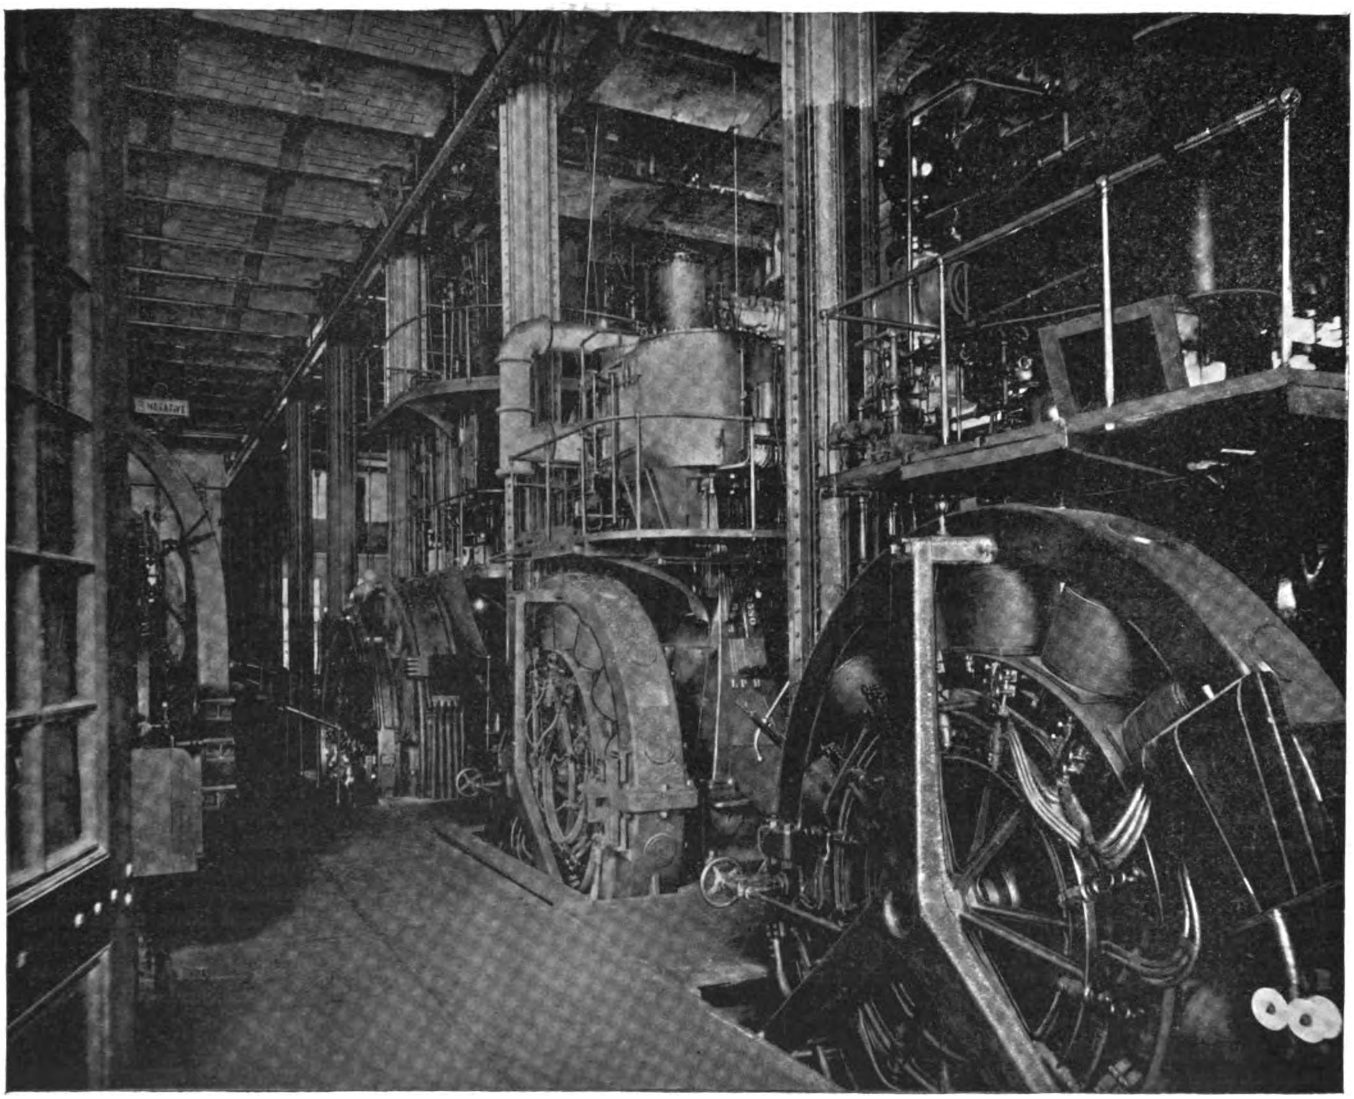
Among those who were with Mr. Edison in this epochal work were John Kruesi, afterward Manager of the Schenectady Works of the General Electric Co., who was developing the underground system; Sigmund Bergmann, who manufactured the electrical supplies; Charles L. Clarke, the well-known electrical patent expert; Julius Hornig, mechanical engineer; H. M. Byllesby, afterward General Manager of the Westinghouse Company; John W. Lieb, Jr., for many years Technical Director of the Italian Edison Company and now returned to the New York Company as its Assistant General Manager; H. C. Patterson, afterward Chief Engineer of the Thomson-Houston Company; Charles S. Bradley, now of the Fort Wayne Electric Corporation; Dr. S. S. Wheeler, afterward Electrical Expert of the Board of Electrical Control and now President of the Crocker-Wheeler Electric Motor Company; E. T. Greenfield; Harrison J. Smith, now General Operating Superintendent, and H. A. Campbell, now Uptown District Superintendent of the New York Company; and others, all men whose names have become well-known in the profession. In fact "Old Pearl Street" was an electrical university in its day, whence Mr. Edison's pupils literally went out into all lands.

The first president of the N. Y. Edison Co., was the late Dr. Norvin Green, Major S. B. Eaton, still of counsel for the Company, being the vice-president and working executive and later succeeding Dr. Green as President. The first superintendent was Mr. Joseph Casho, and his suc-

cessor was Mr. C. E. Chinnock. The original underground two-wire system connected to the Pearl St. Station included 4 miles of feeders and 9½ miles of mains, covering about a square mile of territory, extending from Wall St. to Spruce and Ferry streets, and from Nassau St. to the East River, the farthest point of extension being about 3,000 feet from the station.

Five years' practical operation of the Company had sufficed to demonstrate the success of the undertaking and to justify its extension to the uptown districts. Mr. E. H. Johnson had been a leading spirit from the start and his strong belief in the future of the Company enlisted the support for its further plans of development General Manager during the earlier development and until August, 1890. Mr. R. R. Bowker, then new to the electrical profession, became First Vice-President in February, 1890, and the later development of the Company has been under his direct administration as the active Executive.

There were not wanting the croakers to predict failure of the service when the current was first switched into the mains, but it stands to the credit of the Company that from the very first day of its operation the current has been uninterrupted save for a space of about three hours at the time that the historical old Pearl Street station was visited by fire. The appearance of this station as it was reconstructed after that unfortunate occurrence will be



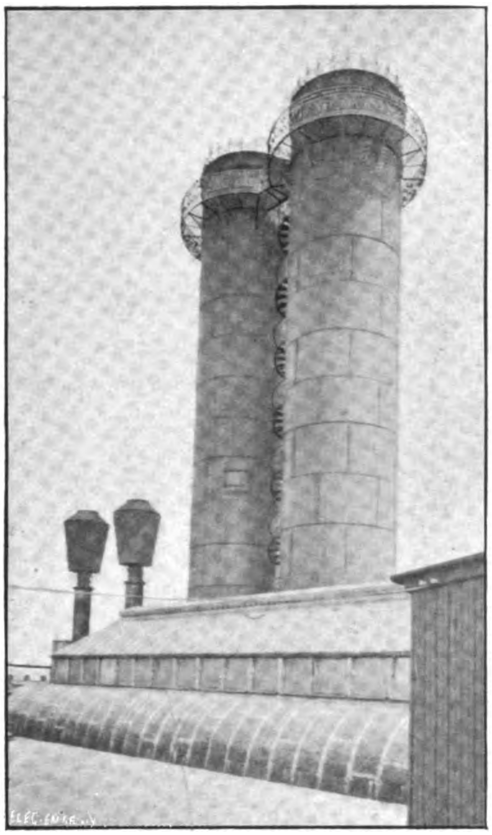
OPERATING ROOM, DUANE ST. STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.

of Mr. J. Pierpont Morgan, whose firm, still represented in the Board by Mr. C. H. Coster, has been one of the guiding factors in its success; and with Mr. Spencer Trask, of the banking firm bearing his name, as President, the 26th and 39th Street stations were built, starting into operation late in 1888, and the beginning of an underground system was made uptown. Mr. Trask has continued in the Presidency till this time except during an absence in Europe, when that post was occupied by his partner, Mr. Geo. Foster Peabody. Mr. F. S. Smithers, another well-known banker, still in the Board, was for some time First Vice-President. Mr. John I. Beggs, now of the Cincinnati Edison Company, was Vice-President and gathered from a glance at the engravings on page 25, which also show one of the Edison Jumbos.

FINANCIAL AND STATISTICAL.

The growth of this Company, especially of late years, has been a striking illustration of the rapidity and extent of electrical development. Its service was at first exclusively for incandescent lighting; motor supply was begun in 1884, and arc lighting in 1889. At the beginning of 1890, the Company counted 1213 customers, 39,815 incandescent lamps, 77 arc lights and 470 horse power in motors on its system. At the end of 1895, it counted 6,675 customers, 271,123 incandescent lamps, 3,424 arc lights, 12,046

Facade of The Duane Street Station, Edison Electric Illuminating Co., New York.



THE "HEAVENLY TWINS."

horse power in motors, or at the rating now adopted by the large Edison companies of 10 16 C. P. incandescent lamps to the standard arc light and 15 to the horse power in motors, an equivalent of 486,060 16 C. P. incandescent lamps.

Current is supplied from six stations, the great Duane St. central station (started 1891), and its annex in the Produce Exchange (1890); the 12th St. station (1894–5); the 26th St. central station (1888); the 39th St. station (1888); and the 53rd St. station (1892). These stations feed current into 203 miles of underground tubing, requiring 608 miles of conductors for feeders and mains.

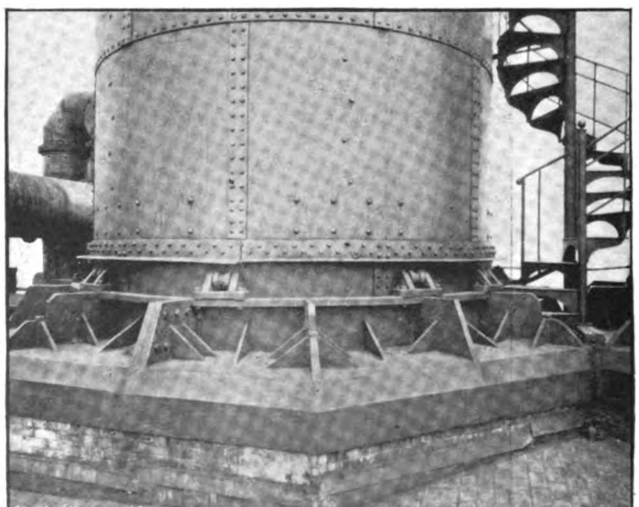
The capital stock of the Company is approximately $8,000,000 and the bond issues $6,500,000, making an investment of $14,500,000, less $500,000 in bank yet to be expended. The gross income in 1895 was over $1,560,000 and the net income approximately $800,000, yielding 2 per cent. above the 6 per cent. dividend. This investment includes, however, the purchase of all the securities (except $64,000 bonds) of the Manhattan, Harlem and Madison Square Companies, now virtually consolidated as a high tension division of the Edison Company. Their 27,800 incandescent and 2060 arc lights bring the Edison totals to an equivalent of 534,460 16 C. P. lamps, and their earnings bring the aggregate income to approximately $2,000,000 gross and $930,000 net. The Edison system proper now extends from the Battery to 79th St., a distance of 5½ miles; with these high tension additions, all now underground, to 125th St., nearly 8 miles. And all this is the development of but 15 years!

DUANE STREET STATION.

As originally planned by Mr. Edison, New York below the Central Park was divided into thirty-eight lighting districts, the old Pearl street station being in the centre of the first district and that part of the City south of Wall street constituting the second district. His "three-wire" development made low-tension distribution practicable commercially more than a mile away and as the richest lighting territory, along the backbone of the island, has been specially cultivated by the Edison Company, it has come about that the successive stations have been built in almost a direct line, nearly north and south. When the permanent central station to replace "Old Pearl street" was to be located, a site was found at Duane, Elm and Pearl streets which was half a mile from either river, one mile from the Battery, and from which could be supplied the whole lower part of the City as far north as Eighth street, a mile and a quarter away, or even 14th street, a mile and a half away. The central location of this site more than compensated, by its economy of copper and prevention of loss in feeders, for the advantage of being at the water side where water could be had for condensing purposes and coal could be delivered directly. Moreover, it was found that the site was above a water-bearing stratum about sixty feet below the street level, which might possibly be utilized for condensing purposes if an artificial water-cooling system were not developed. A plot 100 x 200 feet was therefore purchased from the A. T. Stewart Estate in July, 1890, at a cost of about $280,000.

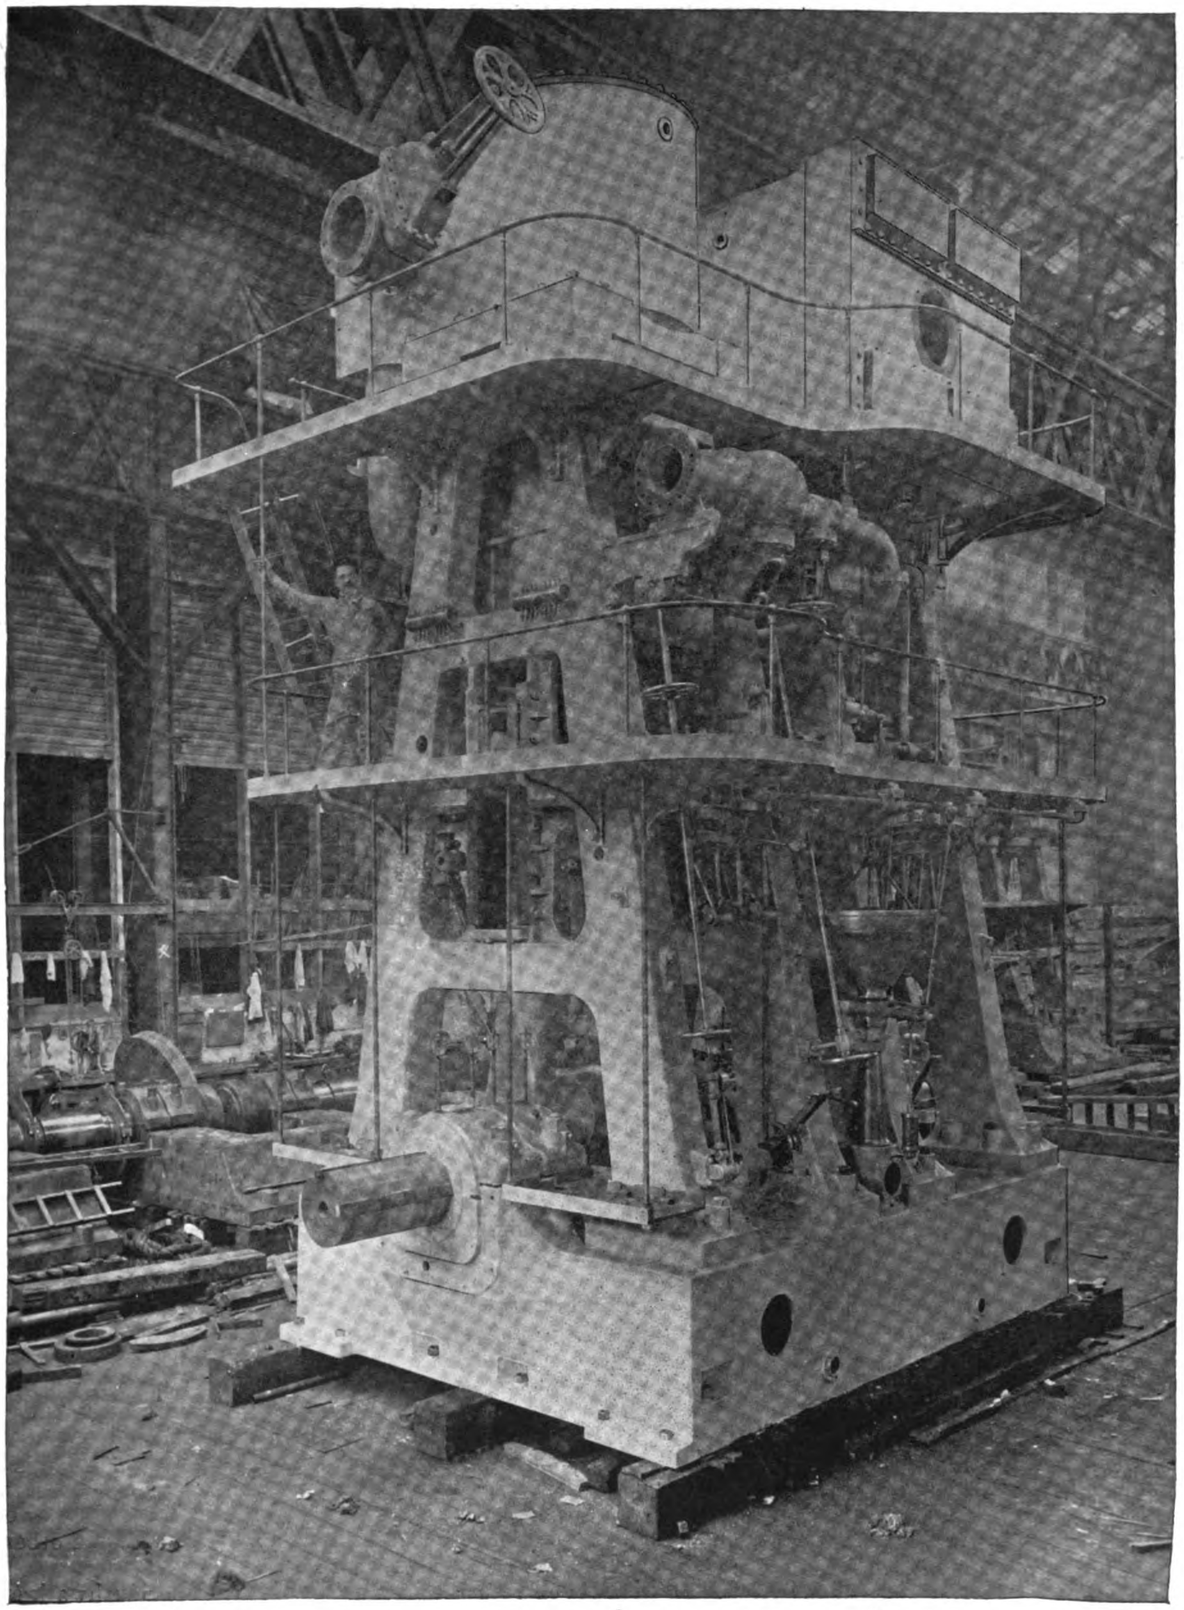
As it was at that time planned to extend Elm street along its present line, space was allowed for that purpose to the west, and the station was confined to a plot 74 feet on Pearl and Duane streets and 200 feet between streets. The change in the plans of the Elm street extension brings the new street to the east of the station and leaves its north façade or station-entrance fronting on an open space. Ground was broken in August, 1890, and by May 1, 1891, when the annex in a basement on Liberty street, with which the old Pearl street station had been supplemented, was given up, its machinery had been moved to the concrete floor on the new site, so that the station was put into commission on that day. The building was, in fact, erected on the old Scotch plan of "building the new church while the old was in use and using for it the materials of the old." As soon as the building reached the second story, all the administrative offices of the Company, which had hitherto had headquarters at 432 Fifth Avenue, fiscal offices at 16 Broad street and other administrative divisions elsewhere, were concentrated in General Offices in the Pearl street end, where they remained until the building was sufficiently completed, in April, 1894, to permit of their removal to the permanent place on the 7th and 8th floors of the new building, which is now at once the largest lighting station of the Company—and the permanent headquarters of all its departments.

The front of this magnificent edifice, designed by the company's architects, Buchman & Deisler, is shown on page 27. The first three floors are built of granite and above this buff colored brick has been employed, giving to the



FOUNDATION OF SMOKE STACKS SHOWING ROLLER BEARINGS.

whole a light and graceful appearance. The edifice is planned from within outward, as all good architectural work should be, and the characteristic features of its which was to be confined within the proper limits of an industrial building, the characteristic industrial application of the structure should be symbolized.



2,500 H. P. SOUTHWARK QUADRUPLE EXPANSION ENGINE IN DUANE STREET STATION. (VIEW TAKEN IN ERECTING SHOP.)

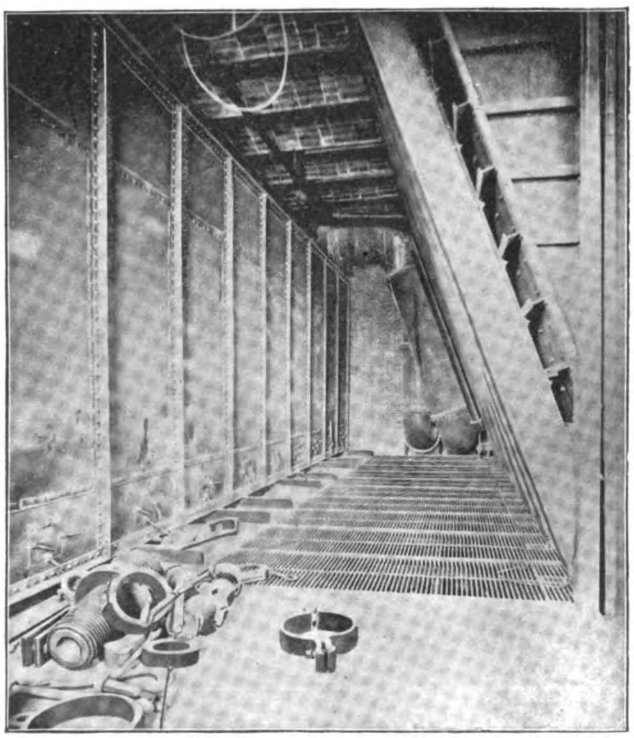
façades indicate the use of the story within, the flat space with a central doorway and balcony representing, for instance, the boiler floor. The directions to the architect were that throughout the ornamentation.

Accordingly, above the broad station entrance, bearing the name of the Company, on the Pearl Street or north side, are four decorated panels which will eventually bear the profile or names of the four celebrities,

Volta, Ohm, Ampère and Watt; the four corresponding panels on the Duane Street side will bear the names of four American electrical worthies. The panels between the hinged windows on the floor immediately below the balcony, as well as in the panels under the eaves of the roof, bear symbolical representations of the multipolar dynamo, while the incandescent lamp has been appropriately embodied in the designs for the string courses and like ornamentation.

THE POWER EQUIPMENT.

As it first presented itself it appeared possible to put down only fourteen 600 H. P. engines, giving a total of 8,400 H. P. The low ratio of power to area at once became apparent and an effort was made to increase the power capacity by the construction of an engine more economical of space. This was done and 1,250 H. P. engines were then considered, raising the station capacity to 17,500 horse power. Nevertheless it was considered desirable to have a number of small units, and two 600 H. P. engines were installed, and a third 600 H. P. engine together with two 1,250 H. P. engines were added. Further study of the problem made it apparent, however, that the available area could be still further economized by the employment of two-crank four-cylinder engines and that by the installation of this type the power could be still further augmented by the placing of nine 2,500 H. P. engines in addition to the smaller ones above cited. This arrangement, as now adopted, is shown in the engraving on the accompanying insert, which shows a plan view of the operating room of the station, the present engines installed being shown in full lines and those contemplated for future installation being shown in dotted lines. When all these engines shall be in place the station will have a total capacity of 26,800 H. P., or, if the third 600 H. P. engine is replaced by one of 2,500 H. P., 28,700 H. P., that is, a horse power for each half square foot of real estate. This is a most remarkable achievement and one which is probably not exceeded in economy of space anywhere in the world.



View of Smoke Flue Under The Coal Bunkers.

A very clear idea of the manner in which it was possible to concentrate steam and electrical apparatus of such capacity on such a small superficial area will be gathered from an inspection of the cross-section of the station illustrated on the inserted supplement sheet. In its main lines the station follows the construction adopted in the older 26th and 39th Street stations erected in 1887-88, and illustrated on later pages. In these instances the placing of the boilers above the engines doubled the power area of the station with a slight additional expense. The principal variation in the design of the Duane Street station consists in concentrating the engines and dynamos on one floor, made possible by the adoption of direct-coupled multipolar generators; in the location of the smoke flue above the boilers instead of below them, this space in the Duane Street station being occupied by steam piping; and in the insertion of two separate floors between the boiler and engine rooms, one floor for heaters, separators, store room, machine shops, etc., while the floor directly under the boilers is occupied by pumps, blow-off tanks, water pipes, ash tramways, etc. It was also decided to make this station the headquarters for the administrative and technical staff of the Company, and with that end in view two floors were added above the coal bunker stories.

With this general description of the station and the causes which led to its present construction, we now propose to enter into the details of the methods of construction and of the apparatus adopted.

THE ENGINES.

The economy in space which has been effected by the practice adopted by the New York Edison Company is due to the adoption of a type of engine design due to Mr. J. Van Vleck, the Company's chief electrician and constructing engineer. This design consists essentially in placing the steam chests in front of and not between the cylinders, and in using radial valve gear, which permit the engines to occupy two-thirds the length which they otherwise would. A distinctive feature of the 2,500 H. P. engines employed is, that they are built on the two-crank four-cylinder type principle which made it practicable to employ quadruple expansion instead of triple expansion. In this connection it might be interesting to note that the New York Edison Company was the pioneer in the introduction of vertical engines of the marine type for driving electric generators, being, as a matter of fact, the first in this country to build an engine of this type of the present sizes.

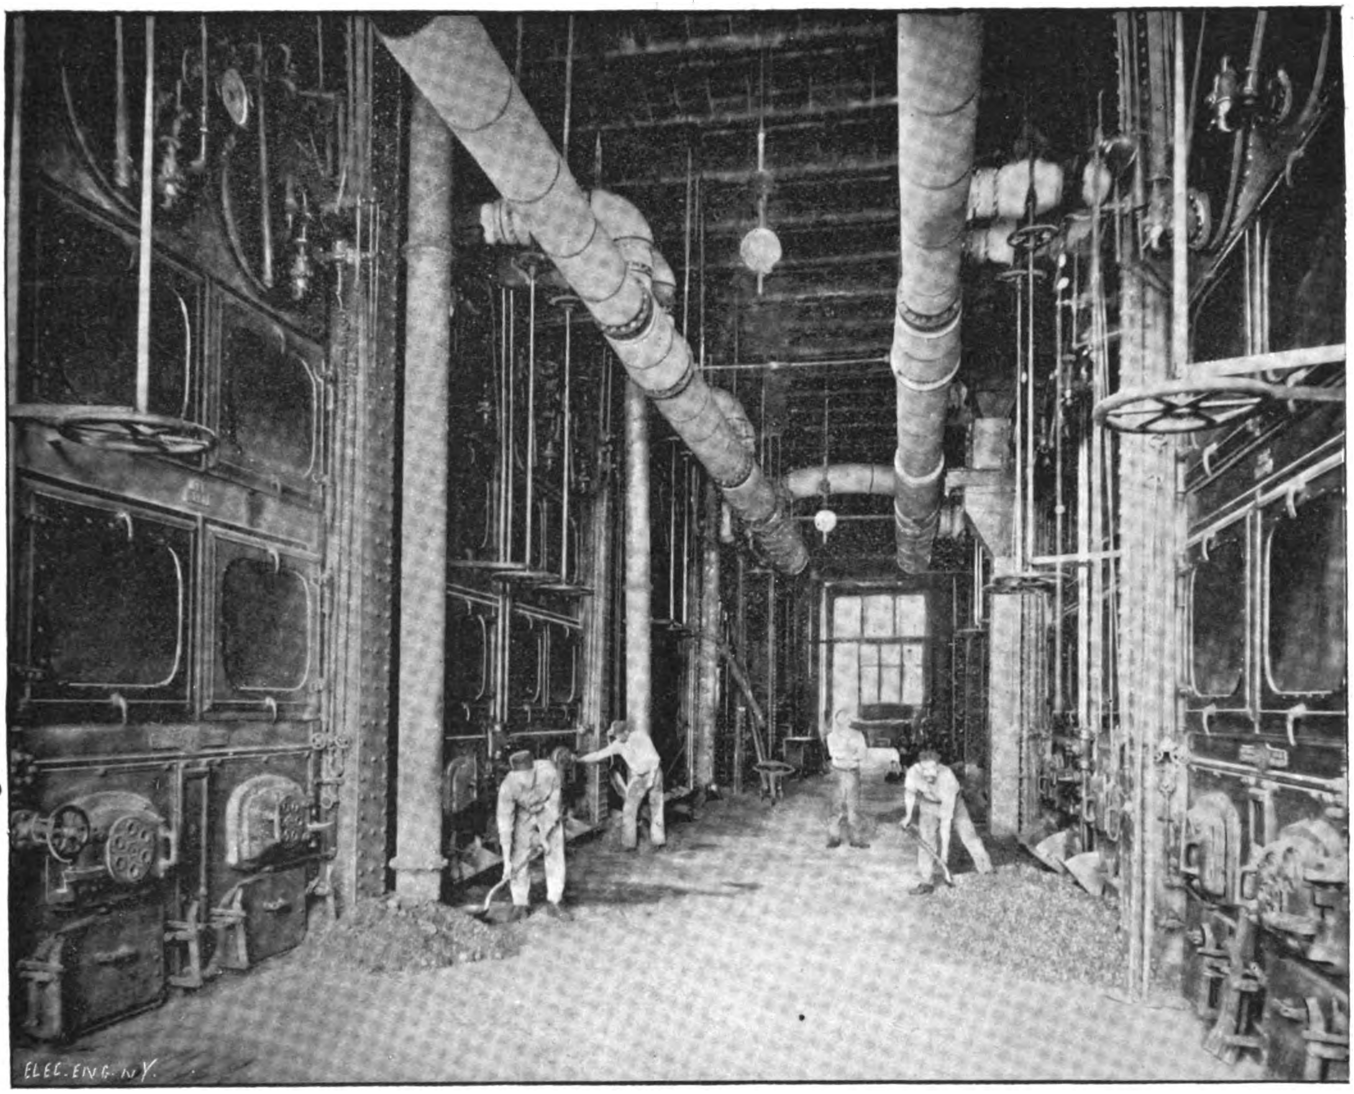
The operating room, a perspective view of which is given on page 26, occupies the full width of the station, the engines, all direct-connected to General Electric dynamos, two to each engine, being arranged in two rows with an aisle through the centre. This room is 29 feet high, 65 feet wide between walls and 160 feet long. At the present time the station contains one quadruple expansion engine of 2,500 H. P., two engines of 1,250 H. P., and three engines of 600 H. P., all built by the Dickson Mfg. Co., of Scranton, Pa.; and a second 2,500 H. P. quadruple expansion engine, built by the Southwark Foundry & Machine Co., of Philadelphia, which has just been put in commission. In addition to the engines above mentioned there has been temporarily placed a McIntosh & Seymour horizontal engine of 250 H. P. The details of the sizes of these various engines are given in a table elsewhere, which also gives the number and power of the engines, boilers and dynamos located in the other stations of the company.

A view is given of the magnificent Southwark engine, on page 29, as it appeared in the erecting shops before shipment. On this engine two 800 K. W. generators are carried directly on the ends of the crank shaft, and run at 90 revolutions per minute. At this speed, and with 200 pounds initial steam pressure, the engine will develop, with maximum economy, 2250 indicated horse power; and a maximum power of 2,800 H. P.

The steam cylinders were so proportioned as to make

the engine most economical both with or without condenser, and are 29", 38", 54", and 72" x 39" stroke. The high and second intermediate pressure cylinders are placed tandem, and work on one crank, while the first intermediate and low pressure cylinders are tandem and work on a second crank, set 90 degrees from the first.

The larger cylinders are placed above and are bolted to the tops of the housings, of which there are four, all of the regular cast iron "A" box type. The lower cylinders are bolted to the upper cylinders in such a way that the bottom head of the upper cylinder forms the top head of the lower cylinder. The top heads of the top cylinders and the bottom heads of the bottom cylinders may be removed to permit examination of the piston packing, the pistons being so constructed as to allow the packing to be replaced from the open ends of the cylinders. All the cylinders are steam jacketed. The high and low pressure cylinders are each fitted with four independent valves of the Porter-Allen type, while the two intermediate cylinders each have a single, double-ported, flat, balanced valve. A radial valve gear is used, the motion being taken from a point on the connecting rods, the steam and exhaust valves receiving motion independently of each other. The cut-off on the high pressure side is controlled by a Porter governor, while, in the other cylinders, it may be adjusted by hand while the engine is running. By a system of disconnective piping, either side of the engine may be run alone in the event of accident, and provision is made to connect the governor to the valve gear on the low pressure side, should the high pressure side be disabled.



View in Boiler Room, Duane Street Station, Edison Electric Illuminating Co., New York.

THE MULTIPOLAR GENERATORS.

A prominent feature of the Duane St. station is the large multipolar generators direct coupled to the vertical compound engines. Though now a familiar sight in central stations, the adoption of this type of machine in the United States is due to the initiative of the New York Edison Co. As a result of their independent investigations, they became convinced that the belt driven dynamo ought to find no place in their new stations and as a result placed an initial order with the General Electric Co., for two 200 K. W. machines; this was followed by the construction of 400 K. W., and led finally to the 800 K. W. machines now used as the standard in connection with the 2,500 H. P. quadruple expansion engines. These dynamos are the largest of their kind employed in this country for electric lighting. The field rings of these machines are of cast steel and it is interesting to note that the present 800 K. W. machines are no larger than the first 400 K. W. machines which had cast iron field rings. The armatures of all these machines have the Gramme ring winding and no separate commutator is employed, the brushes bearing directly on the periphery of the winding which is bared for that purpose. It is worthy of note that the wear on the surface under the brushes is almost inappreciable and

that the design of the machines is such that no sparking or excessive heating occurs even on heavy overload.

THE ELECTRICAL CONTROLLING PLATFORM.

Perhaps the most original and distinctive feature of the operating room is the controlling platform, raised about four feet from the floor, and situated, as shown by the plan on the insert, in the central part of the room, which provides for controlling apparatus to handle 28 dynamos and 132 thousand-ampere feeders within a length of 20 feet. To accomplish this Mr. Van Vleck devised his "Edgewise System," by which, instead of moving field-regulating switches and meter index-hands around the flat face of a circle, these are handled or read on the edge of the quarter-circle.

At the front of the platform, as shown in the left-hand cut on page 33, are the dynamo-controlling devices, so compact that each 800 K. W. dynamo is handled within a six-inch space. Nearest the floor are the controlling switches, by raising the handles of which, each dynamo is thrown on the system. Next above are the regulating quadrants; by raising their handles the field resistances are successively cut out and the power and output of the dynamos increased. Above this is the voltmeter, its index rising as the pressure rises, and above all is the ammeter, its index rising as the quantity of current is increased. Every motion "throwing on," or showing increase of energy, is upward; every motion "throwing off," or showing decrease, is downward; and the attendant has only to glance upward from his switch-handles to see the effect of each act indicated directly above.

At the back of the platform, as shown in the right-hand engraving on page 33, are the feeder-controlling devices, so compact that each thousand-ampere feeder is handled within a three-inch space. Nearest the floor are the connecting switches; by raising their handles each feeder is thrown on the system. Next above are the safety-catches, preventing an excessive rush of current over any one feeder; above these a neat label indicates the location of the feeder-end in the street. Above this again is the ammeter, whose index rises as the feeder carries out more and more current. Above all is the voltmeter showing the pressure at the feeder-end as indicated through the pressure-wires. These instruments are all of Weston make.

The up-and-down feature has an incidental usefulness in the fact that on the row of voltmeters, the pointers, when the voltage of the system is uniform, are in a straight horizontal line, while any variation from standard is emphasized by a deviation from this line.

All apparatus for the positive side of dynamos or feeders is painted red; for the negative, blue, a picturesque as well as practical feature, especially as all positive feeder-connections are grouped at the right and negative at the left end of the feeder switch-board.

Below each vertical rheostat quadrant is a small galvanometer switch which connects the dynamo with a potential indicator. When the proper potential is indicated, the main dynamo switch is thrown up from below and automatically opens the circuit to the instrument.

Situated between each of the main dynamo switches is a single bar knife switch which controls the field-exciting circuit in a manner intended to obviate the difficulties and dangers due to the sudden rupture of a field circuit, on an ingenious method devised by Mr. W. I. Donshea of the Company's staff.

For the charging of the fields, a separate bus is employed so that in case the necessity should arise, the dynamos can be charged from an independent dynamo not connected to the distributing system.

In the arrangement of the station circuits the two outside poles of the dynamos go to a set of positive and negative dynamo switches placed on a switchboard at the back of the feeder switches, as shown in the plan view on the insert.

The current is led to this board from the dynamo terminals by lead-covered stranded cables, which pass under the floor and are brought up to a lug at the back of each switch. The circuit then passes down through the front of the switch, which is mounted on slate blocks six inches thick. After passing through the switch blade it reaches a terminal on the lower part of the board, then passes through laminated strips of copper five inches wide leading to the bus bars to which the laminated strips are clamped. The bus bars consist of two rolled copper bars, one inch thick and fourteen inches wide. If the carrying capacity of the bar, owing to increase of output, becomes too low it can readily be increased by sliding in an additional copper strip without disturbing any connection.

Mounted above, but insulated from the main busses, are the low auxiliary and the high auxiliary busses, to which the short and long feeders respectively can be connected.

The feeder switches, one section of which is shown on page 33, are built up in sections intended eventually to control sixty-six feeders on both the positive and negative sides. At present, forty switches with their corresponding edgewise ammeters above them are in position and occupy a space no greater than ten feet. Each feeder has two switches so as to connect to either the main or auxiliary busses.

LOAD AND PRESSURE RECORDS.

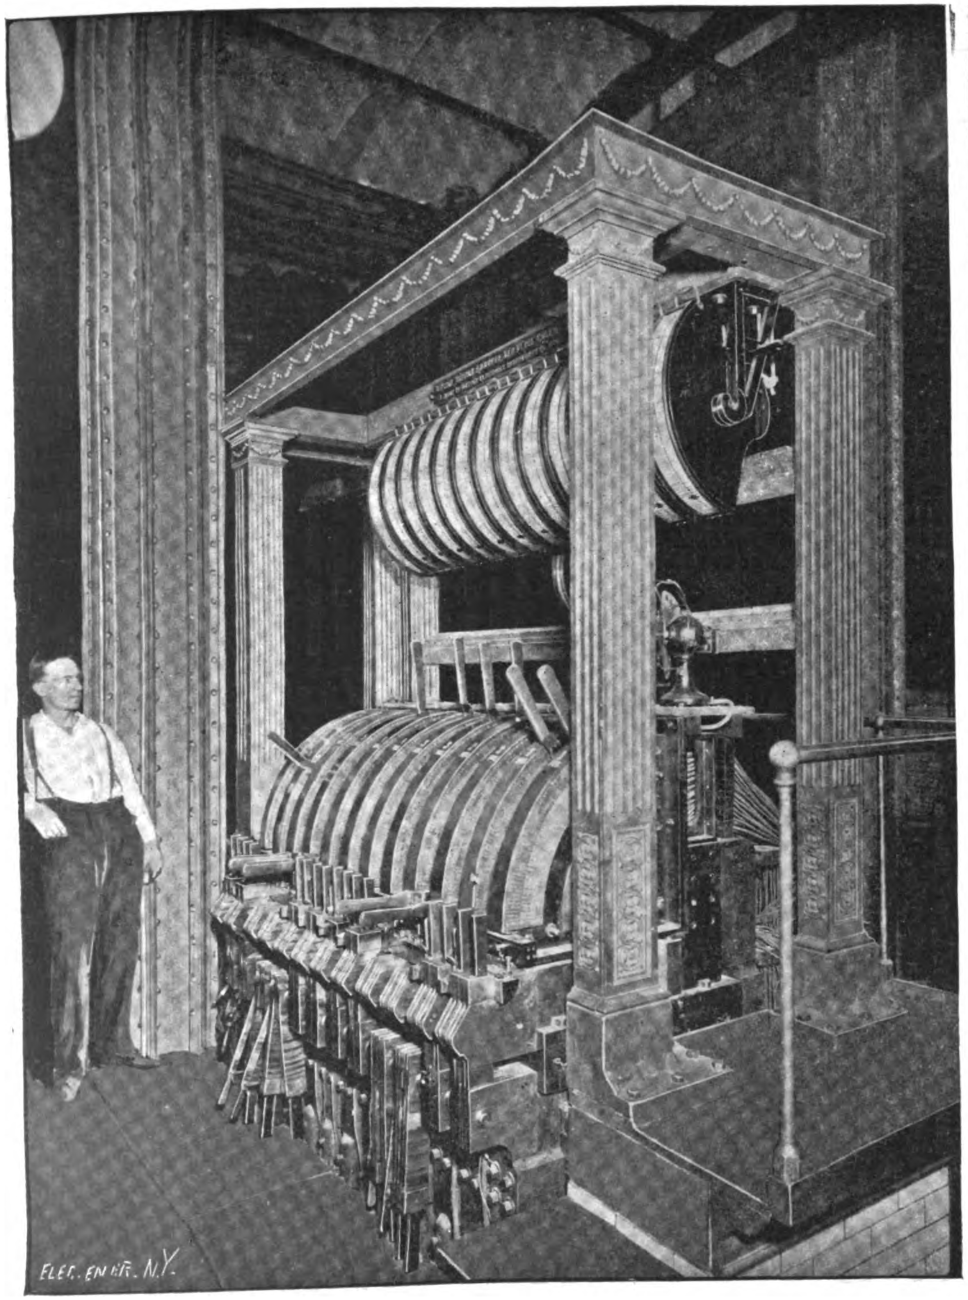
At a convenient point in the electrical regulating gallery a desk is located to which the pressure wires from the feeders are brought, and tests are taken at regular intervals so as to determine the distribution of the pressure on the various parts of the system, while the most important feeders are permanently connected to the main regulating indicators. In addition to this, Bristol recording voltmeters record the pressure on the standard feeder which goes to the most important centre of the district. A load record is taken every fifteen minutes and plotted on tracing section paper. On this chart is also noted the time that each engine is started. From these charts blue prints are made which go to the heads of departments for their inspection.

At regular intervals the indications on the various charts are summated and that shown on page 34, gives the record for the entire system on Dec. 13th last. From this it will be seen that the maximum load on the whole system was attained between 5 and 6 P. M., and reached the enormous total of 63,140 amperes,—a truly remarkable result. This chart also shows the individual record of the uptown and the downtown districts. This record, representing, as it does, the work of the largest electric lighting system in the world, presents a number of interesting features. On Dec. 23, the maximum load reached 66,800 amperes.

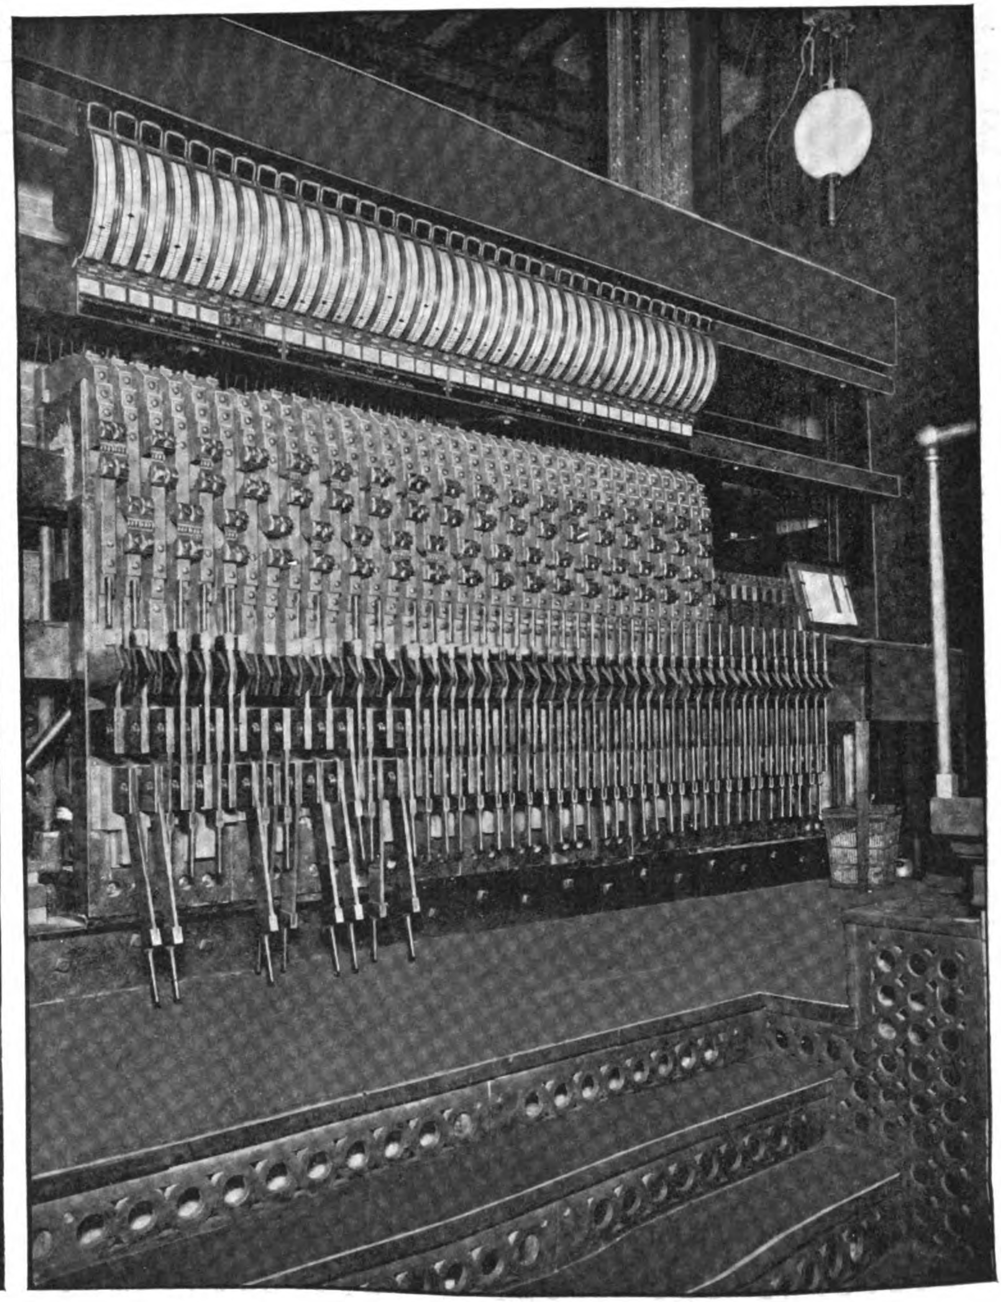
HEATERS, SEPARATORS AND PIPING.

Immediately above the engine room and on each side, are constructed the heater and pipe rooms in which a large portion of the station steam piping equipment is placed. This piping connects directly from the engine room through the open-work ceiling. Through the openings thus made, the hot air from the engine room finds its way into the heater room and finally passes through the blower into the boilers. Thus ventilation of the engine room is assisted and the hot air at the same time economically employed.

The steam pressure carried in the station is 200 pounds to the square inch. The piping, from boilers placed on the fourth floor to the engine below, at such great pressure and for such large powers, presented a most serious problem, and therefore had great care bestowed upon it. The present arrangement embraces two main lines of pipe in the boiler room on each side of the central aisle which is clearly shown in the sectional view and in the perspective of the boiler room shown on page 31. These pipes range from ten to eighteen inches in diameter. From each one of these mains eight 14-inch pipes run down to main lines in the engine room. Into each downtake there are inserted two 14-inch water separators; one of the Company's own design and one of the Stratton



The Dynamo Controlling Section.



The Feeder Controlling Section.

The Van Vleck "Edgewise" System of Electrical Controlling Apparatus, Duane Street Station.

type, making sixteen separators in all. The down-take from each separator leads directly into a 14-inch steam trunk main placed on each side of the engine room, supported directly by the wall. From the top of these mains, steam lines are carried to the engine throttles with the additional insertion of a Stratton separator in some cases and a Climax separator in others.

In order to allow for expansion and contraction in the steam piping, it has been necessary to employ a large amount of copper pipe. This pipe is peculiar in that in connection therewith there has been adopted the foreign practice of banding it, in some cases with copper bands, and in other cases with steel wire. Other portions of the piping are made up of cast iron fittings and double extra heavy wrought iron pipe.

Some idea of the substantial character of this work may be gathered from the statement that the flanges for the 18-inch pipe are four inches thick.

But probably the most striking feature in connection with this piping is the absence of all gaskets. Every steam joint in the station is a ground joint and the claim is well founded that there is not a leaky joint anywhere about the plant. Experience has shown that the engineers of the station were justified in their views, that though the cost of grinding a joint is somewhat in excess of that made with a gasket, as to the durability of the two types there can be no comparison. Every engineer appreciates the constant attention required by joints, and to have this practically eliminated from the station duties is a matter of no small moment, not to speak of the constant loss due to leakage of steam.

Much attention has also been given in this station to the drip pipe system and it is claimed that the steam entering the engine is unusually dry. Certain it is that little trouble from wet steam has thus far been experienced.

Inasmuch as the engines are at present run non-condensing, the exhaust steam is first carried through feed water heaters, of which there are installed four 2,000 H. P. Goubert heaters and one 2,000 H. P. Wheeler heater. These heaters are probably the strongest thus far constructed. After passing through them the exhaust is carried into the main 32-inch exhaust pipes through which the steam finds its way to the roof by three 32-inch exhaust risers which are capped by large exhaust heads.

THE BOILERS.

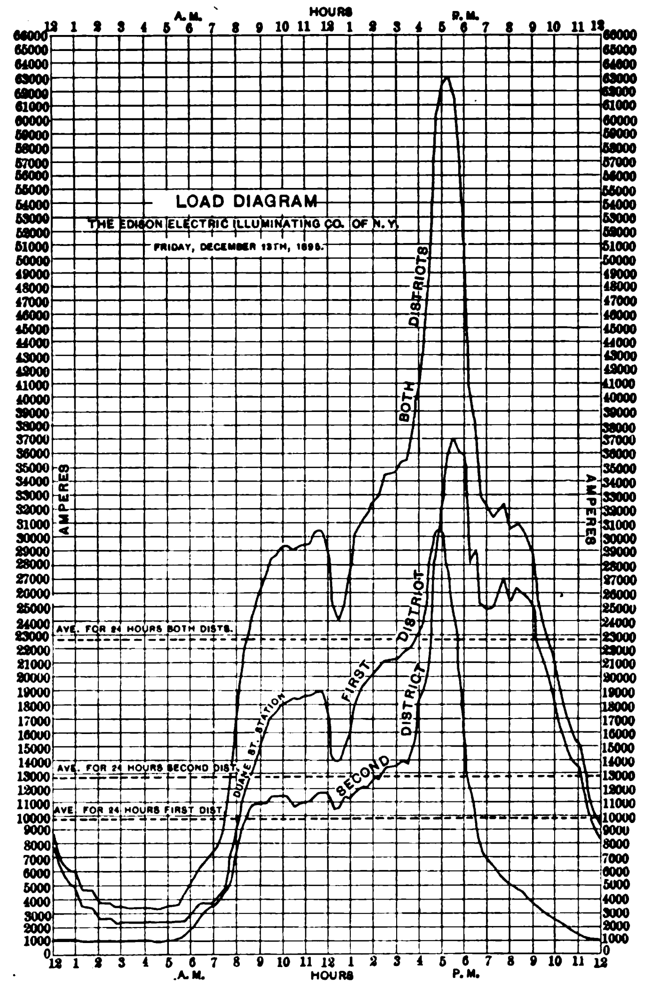
The boiler room, on the fourth story of the building, is a magnificently spacious room, extending from end to end of the building, 200 feet, and ventilated from both streets through the enormous central windows, shown in the view of the façade. A like condensation of power, to correspond with that in the operating room, has been accomplished by the use of huge "double-deck" Babcock & Wilcox water-tube boilers, some ten, and the latest twelve, rows of tubes high, built throughout of steel, designed to carry 200 pounds steam pressure and tested under hydraulic pressure to 300 pounds.

The boiler room, a view of which is given on page 31, contains at the present time twelve of these boilers having an aggregate of 47,472 sq. ft. of heating surface, which is about one-third the heating surface to be installed in the completed plant. All of the boilers are fitted so as to be used under forced draft when desired; and tests have shown that the boilers can safely be forced to over 100 per cent. of their normal capacity without serious loss in economy. It may be added that all the Company's stations are provided with Babcock & Wilcox boilers, aggregating in rated capacity 9,051 H. P.

COAL AND ASH HANDLING MACHINERY AND WATER SUPPLY.

The boilers are fed with coal—through weighing chutes, registering each hundred pounds delivered—from the enormous coal bunkers, occupying the fifth and sixth floors, and capable of carrying over 2,000 tons of coal at a height 96 feet above the street level. Here, as at other stations, several weeks' supply of coal is thus stored, to provide against emergencies arising from snow-blockades, miners' strikes or other difficulties, so that nothing may "freeze out" the customers' supply of light and power. The coal is raised from the street without manual labor, by the Link Belt Co.'s conveying machinery, operated by an electric motor.

With this system the coal is dumped from the street level



Load Diagram for the entire Edison System in New York, for Dec. 13, 1895.

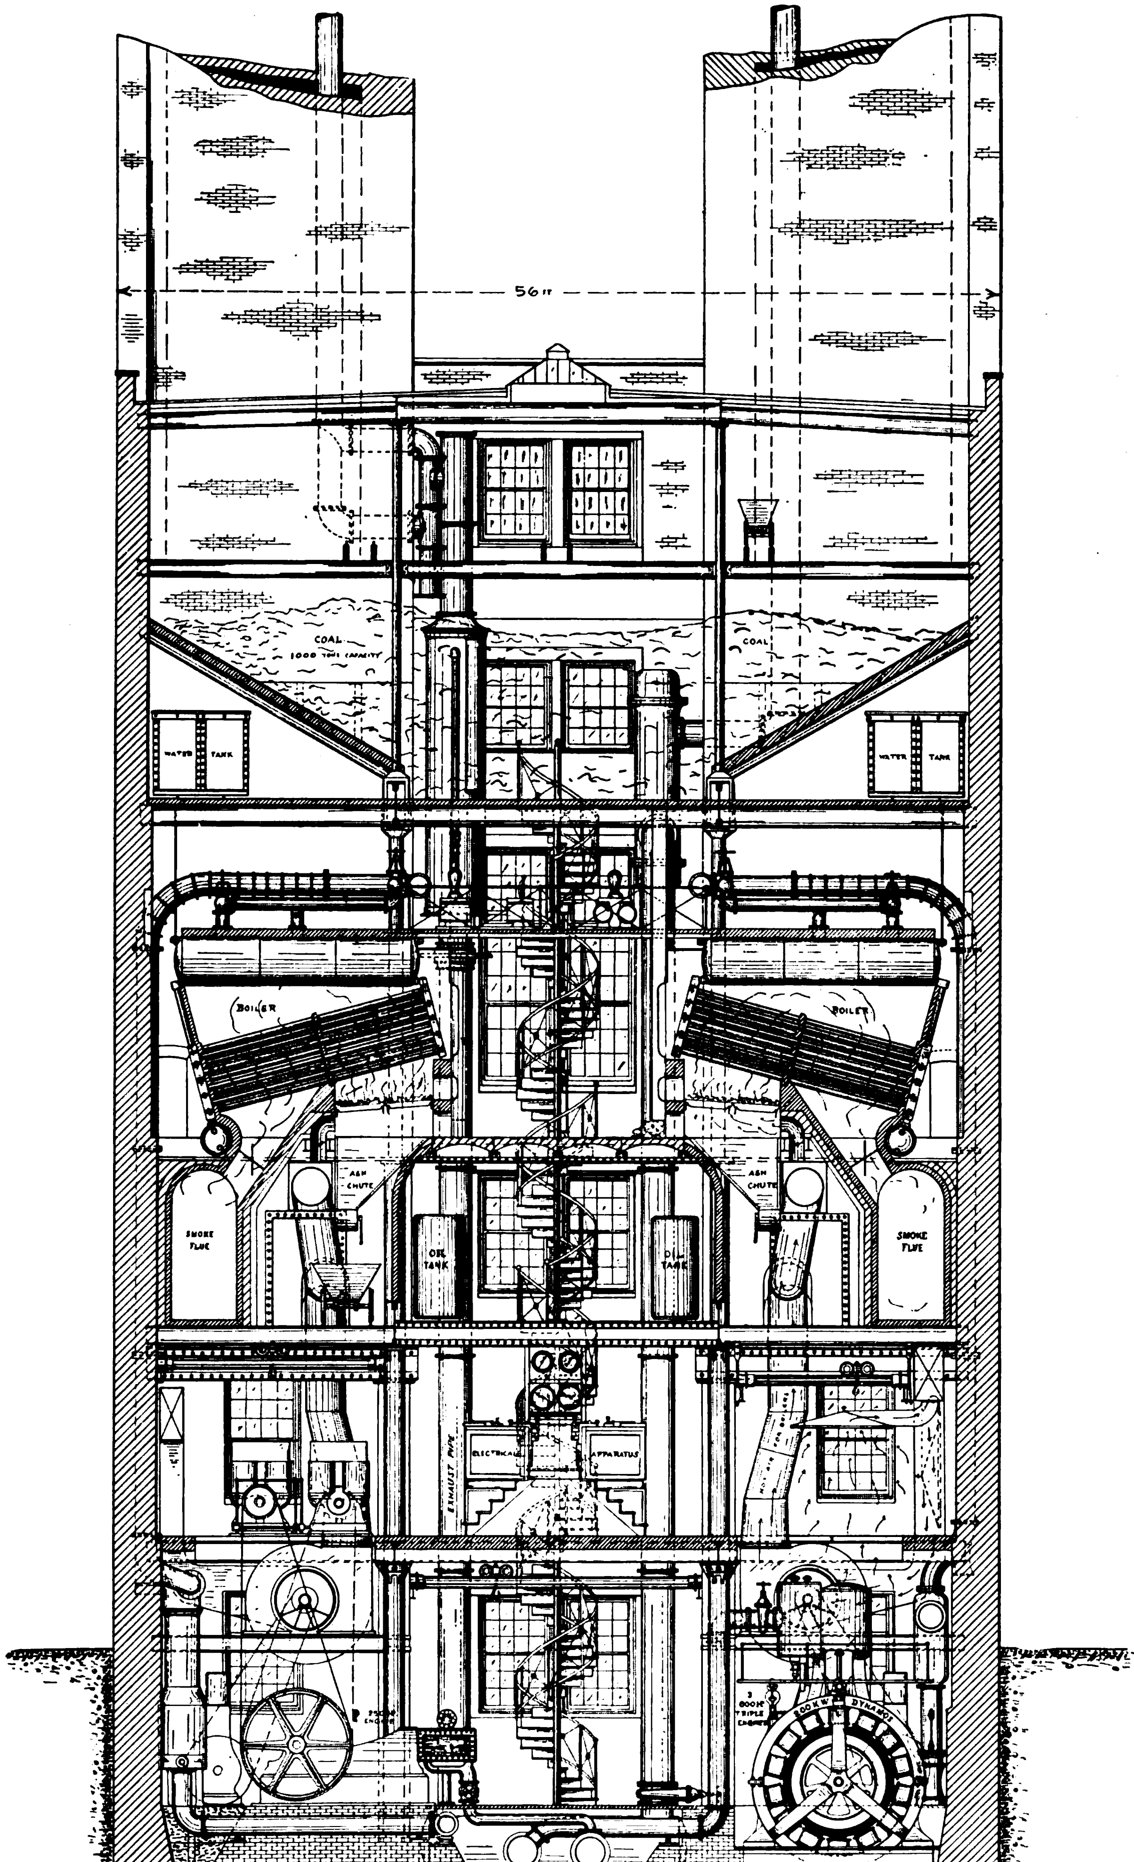
into a hopper suspended on scales, and after being weighed, is allowed to fall on to a screw conveyor which raises the coal to a series of buckets which carry it to the sixth floor and distribute it along the bunkers. Thence everything is done by gravity.

Directly under the boilers, and at the front end, are placed the ash hoppers, which discharge their ashes into ash cars on a tram-way below them. The cars are then wheeled to the end of the building and dumped into main chutes, which discharge directly into ash carts backed in from the street.

Provision has also been made for any sudden interruption of the water supply. For this purpose a series of large water tanks which are always kept filled for storage purposes, are placed on the same floor as the coal bunker. Besides being connected to the city water supply, the Company has wells of its own which can be drawn on for auxiliary or emergency uses.

THE SMOKESTACKS.

The construction of the smokestacks, by which the waste gases from the boilers are carried off, embody a number of unique features which have, indeed, attracted



THE 26TH STREET STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.—SECTION.

attention among engineers abroad as well as in this country Two stacks are employed, built of steel shells 14 feet in diameter, 140 feet long from end to end, 75 feet of this length projecting above the roof. Steel construction was adopted in view of the liability of brick chimneys to crack, especially under forced draft.

The peculiarity of the construction lies in the fact that the foundation, instead of being placed beneath the bottom flange of the steel stack, is placed on top of the bottom flange. This was done in order to save space below the chimney. The steel chimney projects up through the brick foundation and extends through a cap plate on top, around which are arranged a series of roller bearings which permit the steel shell to expand and contract independently of the foundation. This construction is illustrated in the engraving on page 28.

The steel shell is lined with fire brick, which is put on the shell in sections of about 14 feet in height. Each section of brick rests on a cast iron ring riveted to the shell of the stack. Each ring supports the section of brick directly above it, thus enabling any one section of brick to be taken out and replaced without interfering with the section above. This is a most valuable feature, permitting, as it does, of the lining at the bottom of the stack being repaired without interfering with that of the top. The entire chimney structure which begins at the floor above the boilers is supported by the side walls of the building and partly by the steel columns. The appearance of the stacks above the roof is shown in the engraving on page 28, and their close juxtaposition and elevated situation have gained for them the sobriquet of the "Heavenly Twins."

THE UP-TOWN STATIONS.

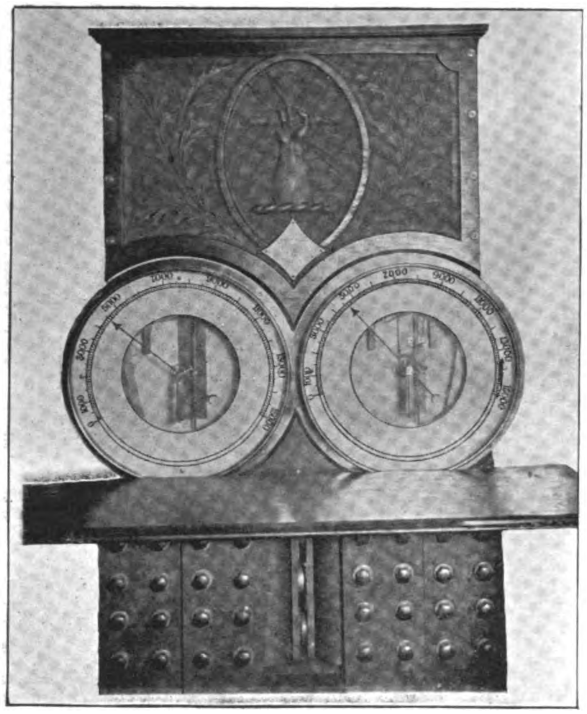
The down-town or first district is supplied now entirely from the great Duane street station, ("Old Pearl street" having been discontinued in 1894), except for occasional reinforcement on dark days or special emergencies by the "annex" for the Produce Exchange neighborhood. The line between the two districts is drawn nominally at 8th street, although the influence of the down-town station extends up-town and that of the up-town stations down-town, so that each part of the system supplements the other at the time of maximum load, which is a little later up-town than down-town.

The up-town or second district is supplied from the large central station in 26th street, which is now used to its full capacity and which like the Duane street station runs throughout the twenty-four hours, and also from stations in 12th, 39th and 53rd streets, which run for one watch of eight hours, or for two watches, varying with the station and with the season. In summer the 39th street station is now discontinued altogether.

All the stations from Duane street to 53rd street are connected by tie-feeders for the purpose of re-inforcing each station from the others and of supplying any local district when the immediate station is not in operation. By the use of a system of controllable disjunctive boxes, on a method planned by Mr. Bowker and worked out in detail by Mr. Van Vleck, these tie-feeders can be separated halfway between stations and thrown on to the mains by motors within the street boxes, operated through the pressure wires in the feeders from the station switchboards. This device permits the use of the tie-feeders for charging during the hours of minimum demand the storage batteries installed at the 53rd street and 12th street stations, and at the hours of maximum demand utilizes the feeders for direct local supply, almost quadrupling the current-carrying capacity of each feeder by thus shortening its length. The saving of investment in copper thus made possible is very large.

The 26th Street and 39th Street stations, completed in 1888–9, have often been described; the section plan is shown on page 35. It should be noted that many improvements have recently been made or are in progress at the 26th Street station, among which are the installation on the roof of a water-cooling tower of Worthington type and manufacture, in which condensing water is cooled by being dripped through thin iron tubes against a current of air which is forced upward by an electrically driven fan, thus enabling the triple-expansion engines to be run condensing, at greatly increased economy; the reconstruction and simplifying of the electrical controlling gallery, in the course of which the original "feeder equalizers" have been almost entirely discarded; and the use of the large Kelvin double ampere gauge, illustrated on this page, which measures the total current output of that station.

This instrument is probably the largest ampere-indicator ever constructed; it was built by James White, of Glasgow, and measures 15,000 amperes on each side of the system. It is worthy of note here that it is mainly due to the New York Edison Company that Lord Kelvin took up the large-dial volt- and ampere-gauges which are now being largely used abroad, especially in England. The instrument consists of a solenoid within which plays a soft iron core supersaturated magnetically by a coil of fine wire



THE KELVIN AMPERE-GAUGES, 26TH STREET STATION.

wound upon it. The opposing force is a spring whichh as been properly aged.

The 53rd Street station is not yet in its permanent form, but has been used to utilize the machinery transferred from the old Pearl Street station and elsewhere. It contains, however, the first storage battery employed in American electric light stations since the unfortunate experiences with storage battery systems some years ago. This is an English battery of the Crompton-Howell type, which has been found useful both as a reserve for use at the maximum period and as a regulator in continuous use to a small extent on the system.

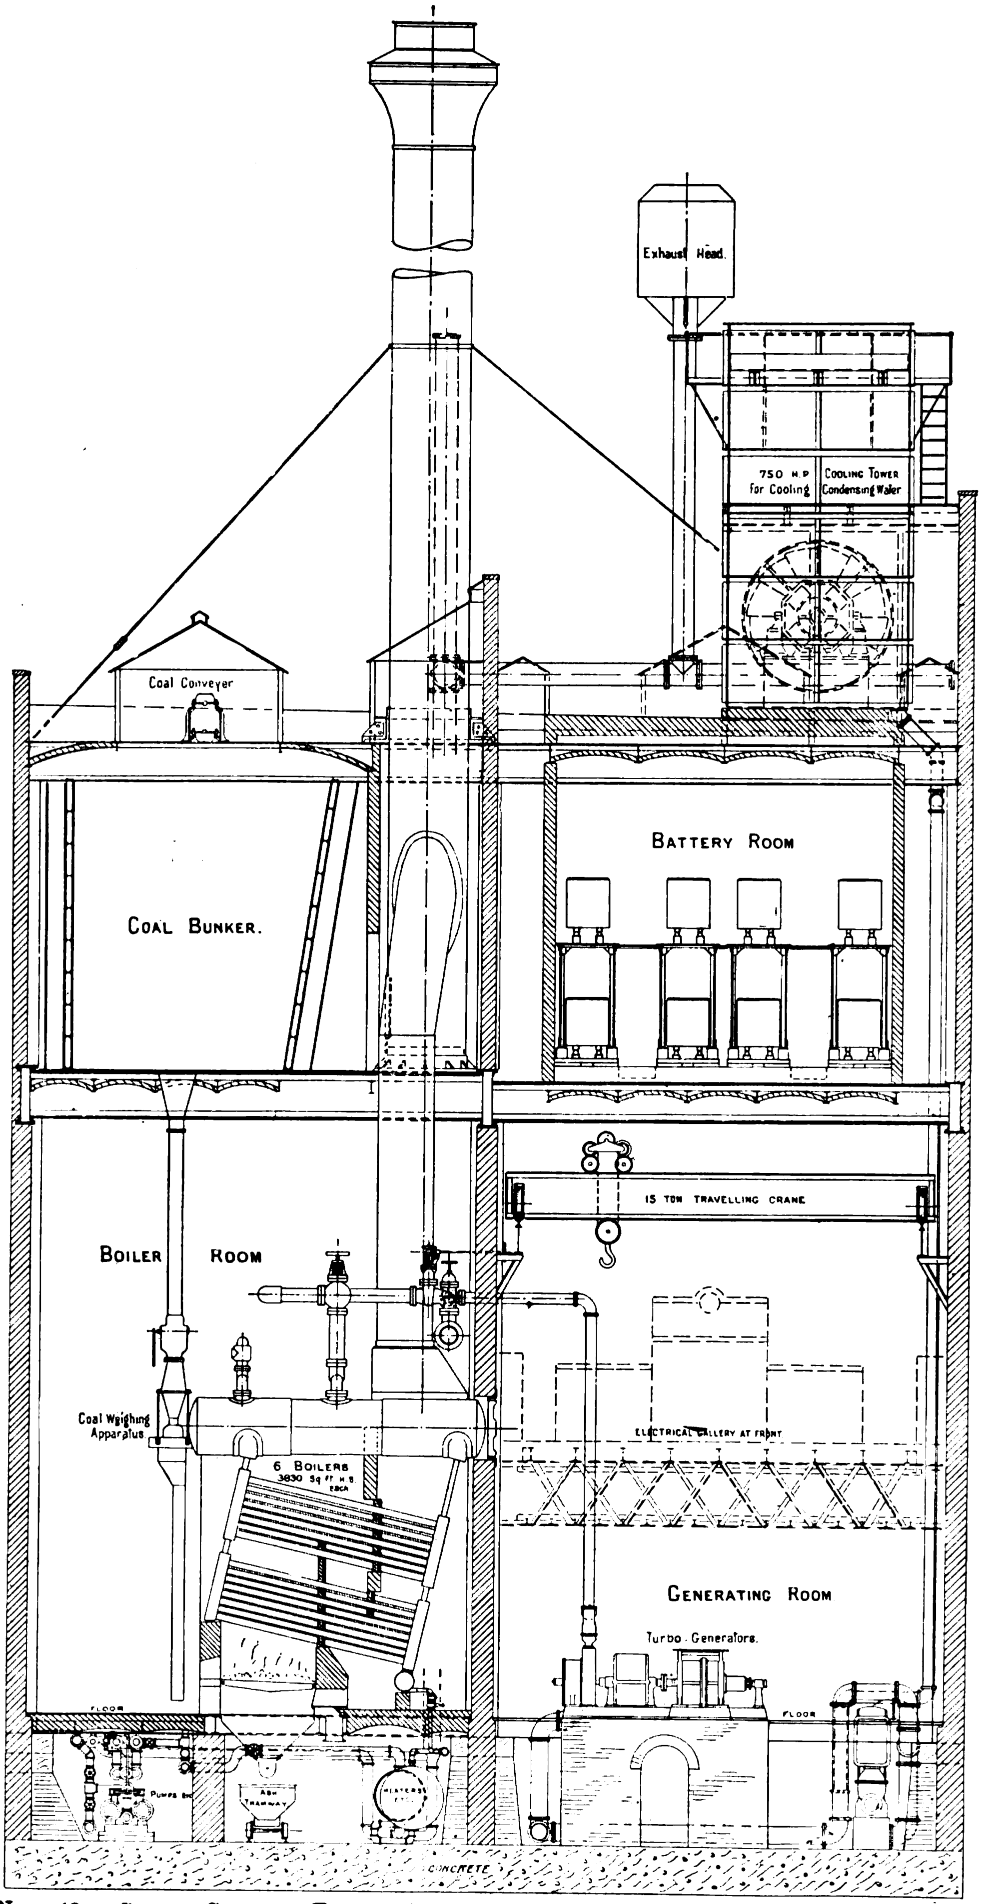
THE TWELFTH STREET STATION.

The 12th Street station, the building for which was completed with the close of 1895, is in many respects a new departure in station construction and therefore calls for special description It has been built, in preference to an extension of the 26th Street station, to supply especially the Union Square neighborhood and that part of the city a mile north of the Duane Street station, which is showing so much business growth.

FAÇADE OF THE NEW 12TH STREET STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.

It is planned to combine the advantages of a horizontal station—the preferable type where land is not too expensive—with certain features of the Company's vertical stations. The boiler room and the engine room are therefore both on the ground floor, dividing the ground space between them, and there is but one additional story, which over the boiler room is devoted chiefly to the coal bunkers and over the engine room provides for a storage battery of large size. The constructive feature of the station is the use of a skeleton or Chicago method of construction, the entire support being of Phoenix wrought iron columns, masonry being used only as curtain-walls. This construction, as utilized in this station, permits its extension either on the boiler room or on the engine room side by simply taking down the curtain wall and adding another row of structural columns on an adjoining lot. The façade is illustrated, from the architects' drawing, on this page.

The station occupies a plot of ground 60 by 100 feet



New 12th Street Station, Edison Electric Illuminating Co., New York.—Section.

and, as shown in the sectional view on this page, is divided, as stated, into equal parts which are taken up respectively by the boiler and engine room. Although all the apparatus is placed on the same floor level, it is planned nevertheless to get one H. P. on one square foot of real estate.

The boiler room will contain six specially designed Babcock & Wilcox boilers, having a total of 23,000 square feet of heating surface. These boilers are unusually high and short; they are of the high pressure type, of steel, and will carry 200 pounds pressure. The steam piping is designed to effect the shortest possible connection between boilers and engines. Over the boiler room are placed the coal bunkers and coal elevating machinery of the Jeffrey type.

The three smoke-stacks are of characteristic construction, being built of sheet steel, 90 feet high, erected without brick lining, each stack to furnish draught for one pair of boilers, thus avoiding horizontal smoke flues. The stacks are prominent features of the neighborhood, and have been nicknamed the "Three Graces."

The generating room, immediately adjoining the boiler room, is designed to have an ultimate capacity of about 6,000 H. P. A radical departure in the engine equipment will be inaugurated by the installation, as the first permanent unit, of a 300 H. P. De-Laval steam turbine which will drive two multipolar dynamos. The illustrations on page 40, show this turbo-generator in plan and side view.

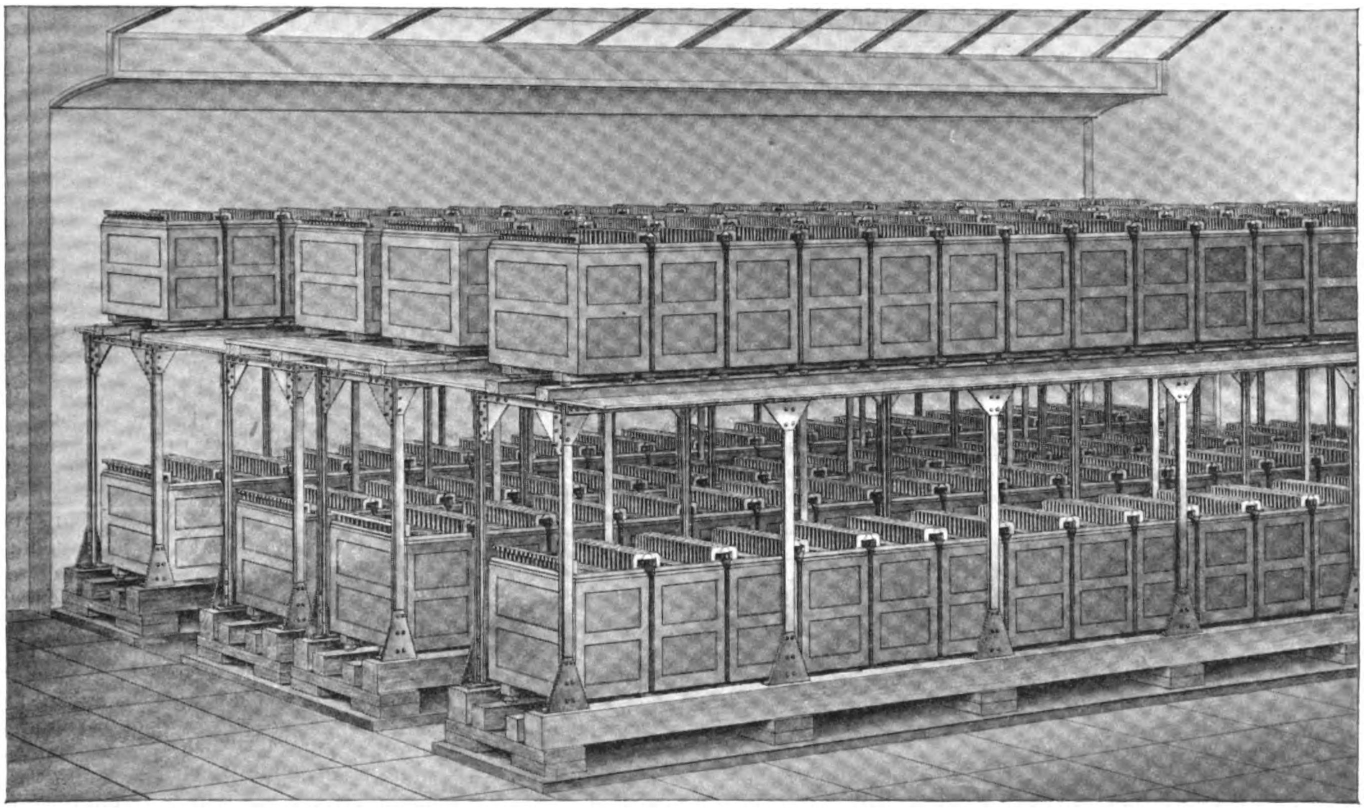
In thus installing a new type of generator, never before commercially used in this country, the Company has again shown its enterprise and the progressive spirit of its management, and thus added another to the many obligations under which the electric lighting fraternity of this country rests to the New York Edison Co.

This station will be run chiefly with engines condensing, and the water for that purpose will be cooled in a Barnard water cooling tower placed on the roof. One of these cooling towers has a capacity of 750 H. P. and space is available for 3,750 H. P. additional. The cooling of the water is effected by blowing air through a series of wire mats down which the condensing water is allowed to trickle. The blower for this purpose will be operated by an electric motor, direct connected to its shaft.

At the south end of the station extending over the front entrance is the gallery for the electric controlling apparatus. The Van Vleck edgewise system, similar to that employed at Duane Street, will be used with the addition of the necessary equipment for operating the storage batteries.

THE STORAGE BATTERY AT 12TH STREET.

Above the electrical gallery and directly handled from it, is the controlling board for the storage battery, separating the battery room proper from the booster room. The battery room at this station, which is shown in the illustration on this page, contains, arranged in two tiers, upon a floor space of 22 x 42, 150 cells of a capacity of 8,000 ampere hours, when discharged at the ordinary voltage, or 4,000 amperes at the double voltage across the system. This has required the use of unusually large cells, each of which contains 19 positive and 20 negative plates, the positive plates being of the pasted grid (Tudor) type and the negative plates of the Chloride type. The entire installation is supplied by the Electric Storage Battery Co. of Philadelphia.



STORAGE BATTERY ROOM IN 12TH STREET STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.

The installation of this storage battery, at this nearly central point of the system, is part of an interesting general plan, which may ultimately include also storage batteries in annex stations near the extreme ends of the system.

The tie-feeders are arranged, as explained, so that the 12th Street station may be connected directly with the Duane Street station or the 26th Street station, and the battery can thus be charged from either of those points at ordinary voltage, by help of the "booster" located in front of the battery room, the direct current Edison system enabling the Company to avail itself of this method of accumulating reserve. This enables the Company to utilize its generating machinery at either of these stations during the minimum hours and at times when engines are running with but partial load, with great increase of economy in operation. It is intended to run the generating machinery at the 12th street station only during one watch of maximum demand, and to supplement this supply during maximum hours with current from the battery. The battery will also supply this part of the city, during hours when the 12th street station machinery is not run.

It is also useful as a reserve for the entire system, and it may help to make possible the shutting down of the Duane Street station from Saturday night to Monday morning, and perhaps limiting its operation to two watches instead of three. The possible uses of a storage battery, it will be seen, will be thoroughly worked out in this interesting installation.

THE UNDERGROUND SYSTEM.

Mr. Edison, with wise prevision, early foresaw that the great cities must ultimately require all electric conductors to be laid, like the gas and water systems, underground. Accordingly, with the co-operation of Mr. John Kruesi, he worked out a complete underground system, so that when the inevitable controversy came in New York the Edison Company was safely beyond criticism from the city authorities. His plan, as is well known, was to lay mains in front of the houses on each block, joined at the street corners into a crib or network, and to supply current to this system of mains by feeders running from the central station to different points on the network. Of his original "two-wire system" 4½ miles of feeders and 10½ miles of mains were laid altogether, in the down-town district.

After the "two-wire system" had been laid, Mr. Edison invented his "three-wire system" of distribution, one of the most important developments in the electrical industry, which, by introducing a third wire, made it possible to double the working pressure, to greatly decrease the copper necessary for a given output of current and, by lessening the "drop" or energy losses, to greatly extend the area of supply. All the up-town district, as it was developed, was installed on the three-wire system, which is carried not only throughout the street system but also through house installations, incandescent lamps being nearly evenly

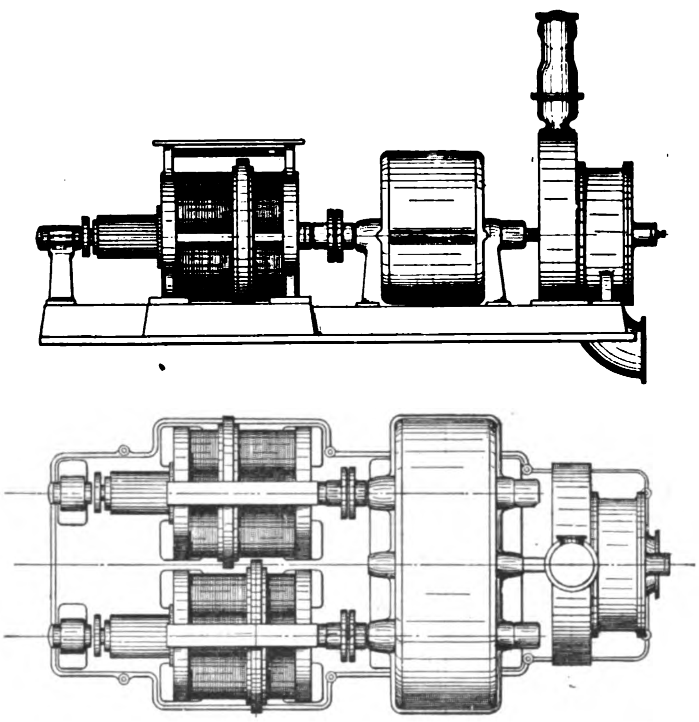
"balanced" on the positive and on the negative sides. The two-wire system has been almost entirely re-laid and the three-wire system has been extended till the Company to-day has, as already stated, over 203 miles of ducts, containing 608 miles of copper conductors, under the pavements of New York City. A map of its system of mains is given with this article, in the supplement.

The standard sizes employed for mains are 150,000 C. M., 200,000 C. M. and 350,000 C. M. in area. In the mains the neutral wire is of the same cross-section as the outside wires, while in the feeders, running from 400,000 to 1,000,000 C. M., the neutral wire is one-third the area of the other two.

Edison tubing is the standard type of underground conductor employed, but a small quantity of Siemens iron armored cable, made by the General Electric Co., at Schenectady, has also been laid down as feeders radiating from the Company's 53d St. station.

On the New York Edison system the voltage is approximately 120 volts on either side, or 240 volts between the outside conductors, incandescent and arc lamps being placed on the lower voltage and motors usually on the higher voltage. But one system of conductors is used for incandescent and arc lighting, for power and for heating and kindred purposes—an advantage which has gained for the Edison system much of its commercial success.

The Company brings its service inside the front wall of a customer's house, protecting it at the end by a service-end box designed by Mr. Van Vleck, or by the Van Vleck cut-out, either of which is so arranged as to make it easy to shut off all electrical connection between the house and



Dynamos. *Reducing Gear.* *Steam Turbine.*

THE DELAVAL STEAM TURBINE, 12TH STREET STATION.

the street system, when desired; and it furnishes also, to be set by the wiring contractor, an Edison meter for measuring the amount of current used by the consumer. An illustration of the most modern devices for service connection is shown on this page.

The consumer is protected against abnormal flow of current not only within his house, by means of the fusible safety-catches invented by Mr. Edison as a part of his original system, but by successive safety-catches throughout the street system. There is one set between the house and the street service; another set between the mains and the junction boxes at the street corner, into which, when they are "feeder-end boxes," the feeders run from the station; another set at the feeder-ends, and finally there is a set within the station itself. In this important feature electric supply has a decided advantage over gas supply, which has no such automatic cut-out.

Another advantage of the Edison underground system

SERVICE CONNECTIONS ON CUSTOMER'S PREMISES.

to the consumer in New York is that the system of network gives usually a double supply from either end of the street as well as a supply originating from several stations. Thus, if anything happens to one main, or to any one feeder, or indeed to any individual station, the consumer does not lose his supply as he would on the ordinary single loop system.

The feeders enter the station from below the surface of the street, coming through the wall of the vault, taking the Duane St. station as an example, in pipes 6 inches in diameter, as shown in the engraving on the opposite page. Passing upwards they are run along the ceiling supported between porcelain knob insulators, after the manner shown, and are then led through the cable runway, shown in the sectional view, which runs the entire length of the station. These runways consist of piers built up of brick in which earthenware pipes are laid in cement. Through these the stranded cables connected to the feeder ends are led to a point directly below the electrical gallery, and in these runways also are carried the cables connecting the various machines with the electrical gallery. Stranded cables insulated with rubber are used for this purpose. A cable vault is located at each end of the station, that on the Duane street side for the feeders running south, and that on the Pearl street side for those running north.

THE METER SYSTEM.

One of the fundamental principles laid down by Mr. Edison governing central station work, was that the customer should be charged for the exact amount of current used, and that the method of charging by contract ought to find little place in a properly managed current distributing establishment.

When Mr. Edison began the development of his system, there was no commercial method of measuring, at the consumer's premises, the current supplied for his use. His

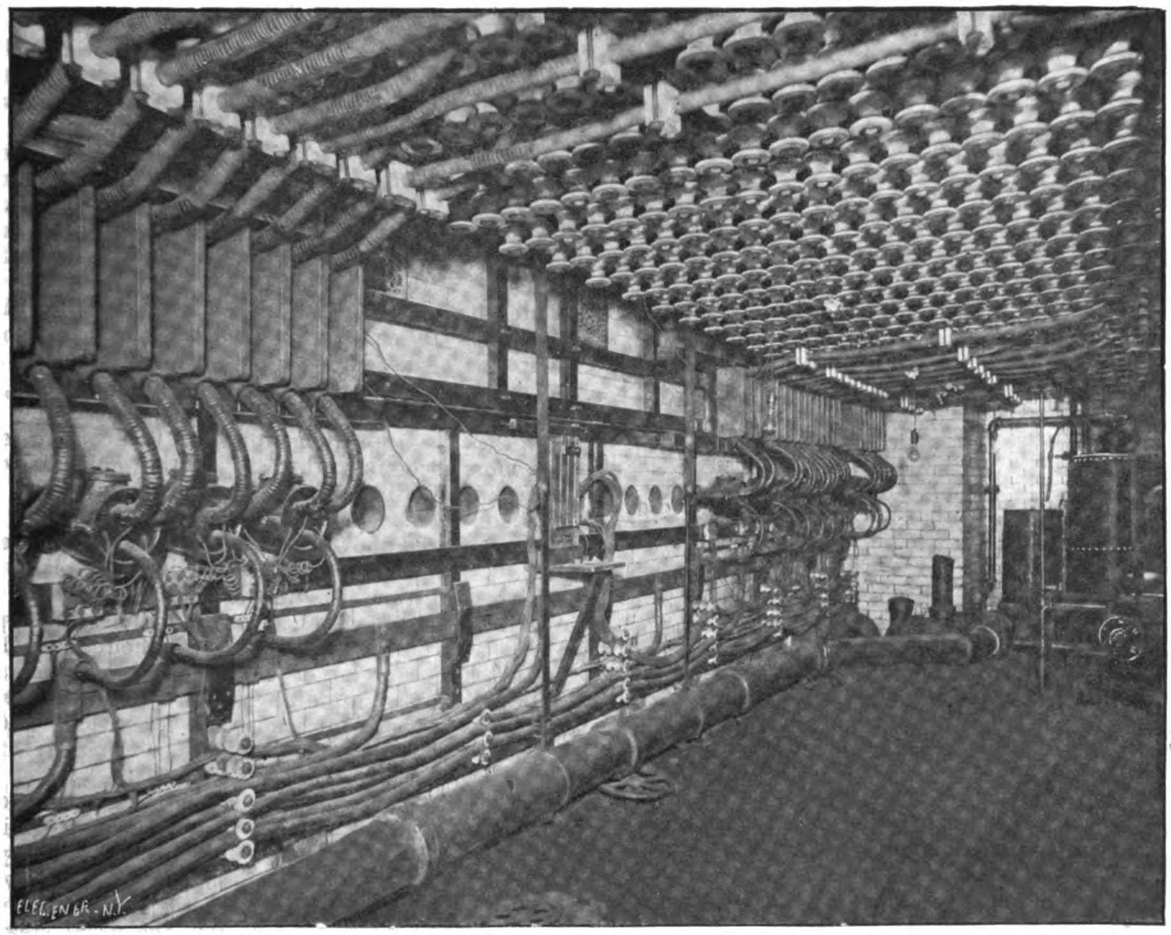
fertile brain promptly devised several practicable meters, mechanical and chemical, from which he selected his well-known electrolytic ("chemical") meter as meeting with accuracy both scientific and commercial requirements. It had the one disadvantage that it could not be read directly by the consumer, but necessitated the weighing of the plates. The New York Company has recognized the desirability of this feature of an ideal meter, but has not yet found any type combining direct reading with the accuracy and simplicity of the Edison "chemical" meter; so that all current delivered on its system is still measured by this means.

A glance at the engraving on page 42 will illustrate the simplicity of the principle of Mr. Edison's well-known meter. A glass bottle contains two zinc plates, immersed in a standardized solution of sulphate of zinc. The electric current enters the bottle from the terminal of one plate, passes through the solution and goes out through the terminal of the other plate. In so doing it disintegrates from the "losing plate" particles of zinc and deposits on the "gaining plate" their exact equivalent. The amount thus transferred is in exact proportion to the amount of current passing through the bottle, according to a well-known physical law. The quantity of current shunted through the bottle is a definite proportion of the quantity going directly into the house, "resistances" within the meter fixing the exact proportions. The exactness of this proportion is verified before the meter is placed on the system, and can be checked at any time by electrical tests on the consumer's premises.

Each three-wire meter contains two pairs of bottles, one pair on the positive, the other on the negative side of the system. The same amount of current passes through each bottle of the pair and by weighing the "gaining plate" in one bottle and the "losing plate" in the other, a double check is obtained.

After a meter is installed on a customer's premises it is then sealed until the next round of the "meter-wagon." The Company's representative unseals the meter, removes the bottles, replacing them by others whose plate-weights have been carefully recorded, and brings the four bottles in a four-part box back to the Meter Department. Each meter has its proper number; each bottle-box has an identifying label which bears the record of the bottle-changing and meter-inspection; and the plates within the bottles are also specifically numbered—so that confusion between the records of different consumers is practically impossible.

All the meter work of the Company is concentrated and organized in the Meter Bureau at the north end of the eighth floor of the Duane Street Station. The whole establishment is so arranged, with glass partitions, that each process of weighing, calculating and verifying, though handled in separate offices, is under the direct eye of the superintendent as he sits at his desk.



THE NORTH FEEDER VAULT, DUANE STREET STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.

As the bottles come in from the day's trip the plates are taken out, carefully dried and passed on to the weighing room, while the solution is decanted, filtered and re-standardized in an ingenious series of tanks from which it is delivered, at the proper standard, through four faucets filling all four bottles at once.

Meanwhile in the weighing room, carefully trained weighers, most of them girls, using Becker's balances of the finest accuracy, record the weights of the plates, on the consumer's meter card, and a second weigher makes an independent weighing, the results of which are compared with those of the first. This meter card also gives the weight of the plates as they went out to the consumer, and

the differences in weight, carefully reckoned from charts previously calculated, to prevent clerical error, and accurately verified, are made the basis of the bill charge. The consumer's card thus contains the history of each charge, doubly checked at each point with the initials of each person concerned, furnishing evidence directly available to the consumer, or in the courts should bills be questioned.

The incoming plates, having been weighed, are then cleaned and re-weighed with similar precautions, numbered, and recorded on the consumer's card as they go out in the bottles intended for his meter.

The Company has taken the utmost pains to make its meter system absolutely accurate, within the limits of human fallibility, and the few errors in bills which are found in the course of a year, are easily traced and corrected. Questions are always raised, and always will be raised, as to the accuracy of any kind of meter, gas, water or other, and the N. Y. Edison Company meets this point by opening its records and showing all its meter operations to any consumer who wishes, and by enabling him, if he desires, to follow the plates of his own meter from his house to the desk of the bill-clerk.

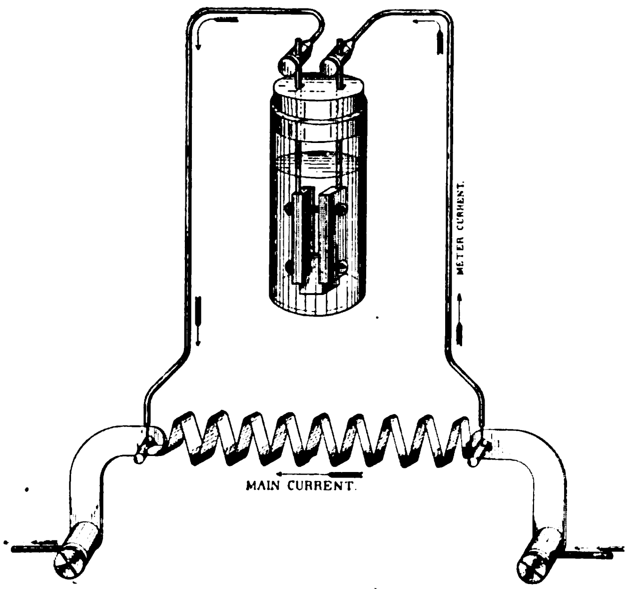


Diagram Illustrating Principle of Edison Meter.

The identification and double checking at every operation are wonderfully complete; and no employé can have motive or opportunity for modification, either for or against the Company, of the correct result.

USES AND PRICE OF CURRENT.

The uses of the continuous low tension current cover almost every service to which electricity can be put. The rates charged by the Company vary according to the nature of the service, but are almost without exception based on actual meter records, and they are the same to all customers for the same class and amount of service. From the very beginning the Company has encouraged the liberal use of light by the inauguration of a graded system of discounts depending upon the amount of current taken.

The basic price of incandescent lighting has been brought down throughout the system to the uniform rate of one cent per (16 c. p.) lamp hour, including the supply of incandescent lamps, and in addition to discounts depending on the amount of bills (on those over $100 per month) the Company has introduced within the past year additional discounts, on bills over $200 per month, dependent on the average amount of burning (if over 50 hours per month) of all lamps installed,—a system since followed by the other electric light companies in New York City. By thus increasing discounts, the Company has voluntarily and continuously reduced the average price of current for electric lighting, and by offering inducements to large consumers to take station current instead of installing isolated plants, it seeks to increase its output without proportionate increase of expense, with the aim of ultimately giving to all consumers, small as well as large, the benefits of reduced prices. This is the declared policy of the administration of the Company, which aims to divide the benefits of new economies and improvements fairly between consumers and stockholders.

The result of this system is that the largest consumers are obtaining current at the rate of 8 cents per kilowatt hour, including supply of lamps. We doubt whether an isolated plant even of the largest size can be found which can show a lower cost than this, when all the items that go to make up the cost of electric lighting are considered. Indeed the owners of new large buildings now erecting in New York are more and more realizing the fact that, considering the initial cost of installation of engines, dynamos, boilers, pumps, together with the cost of coal, attendance, repairs, etc., it is cheaper to take current from a central station, whose sole business it is to manufacture current at the highest possible economy,—in contradistinction to the light, wasteful load which isolated plant dynamos generally carry for the greater part of the day's run.

The same principle of graded discounts applies to arc lighting, which department of the Company's work has made rapid strides during the last few years. The rate of charge is 10 cents per hour for each 8 ampere arc lamp, with discounts which brings the cost down to 6½ cents per arc lamp hour, including lamps, carbons and attendance, and to 5½ cents, where the customer furnishes the latter items himself. It is coming to be more and more recognized that arc lighting holds its own as the cheapest of all illuminants, despite all the recent improvements in the use of gas.

We referred above to the gradual recognition of the fact by owners of buildings that isolated plants were not paying investments; all the arguments there used and many more can be applied to the innumerable applications of motive power scattered throughout a modern city. Indeed the supplying of current for motors has advanced with enormous rapidity within the last few years, and at the present time no less than 12,000 H. P. in motors are supplied by the Company from its service. Among the purposes to which electric motors are largely applied are passenger and freight elevators of which no less than 300, aggregating 3,000 H. P., are now being operated from the Company's mains.

The reason of the electric motor's popularity for this particular purpose will be readily understood when one stops to consider that by its use the usual steam engine plant and all its attending cost and nuisance are wiped out of existence, and in their stead we find a neat machine, with but a single moving part, tucked away in a corner of the cellar, or bolted to the beams under the roof, which requires no attention whatever from the owner, who for a small monthly fee, can transfer the entire care of the machine to the central station. And all this luxury, for such indeed it has come to be, can be had for 10 cents per H. P. hour, with discounts which bring the cost down to 5 cents per H. P. hour for customers using 1,500 H. P. hours per month.

Besides the elevator work above referred to, the Company furnishes current for hundreds of electric motors driving printing presses, pumps, sewing machines, lathes, planers, organs, grip hoists, exhaust fans, table and desk fans, and for scores of other purposes. The Company leaves the customer free to install his own motor, with the result that there are no less than 40 different makes of machines connected to its circuits. For all purposes requiring a small quantity of power, the electric motor is conceded to be not only the most economical but the most

convenient of any thus far devised. Its introduction in many small industries has not only greatly increased the output but has made the work lighter and in this respect is beginning to make itself felt as one of the factors making for increased comfort among the masses of toiling humanity.

To the above uses must be added that of electric heating and cooking, for which increasing amounts of current are being called for month by month. The rates for this service are the same as those for motive power.

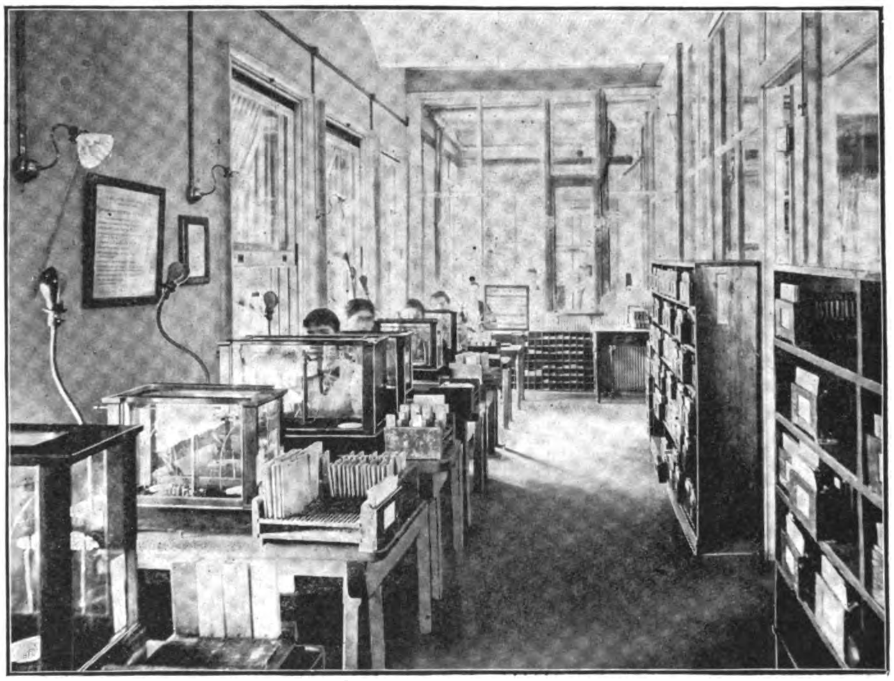
GENERAL VIEW OF METER DEPARTMENT.

THE INSPECTION DEPARTMENT.

It is through the Inspection Department that the Company comes in most direct contact with its customers. On the Inspection Department first of all devolves the work of providing for new customers. After an application blank for current service, has been signed by the customer and the usual contract made with him, an order to make the required connection is given to the Installation Department, which carries the mains to the service outlet in the cellar or vault of the building to be lighted. The Edison Company itself does no wiring whatever of buildings, preferring to allow its customers to have this work done by outside contractors. As, however, it is necessary to guard against bad wiring work, which might cast discredit upon the system, the Company before turning on current makes an inspection, in co-operation with the New York Board of Fire Underwriters and the New York City Electrical Inspection Bureau. The Company's inspection is made particularly with reference to the service rules relating to the balancing of the system, the metering and division of current for light, heat and power and the proper placing of switches, cut-outs, etc.

To this department also are referred all customers' complaints. If, for example, a customer complains that his bill is too high, an inspector is sent to investigate. The records are examined, and frequently a special test is made on the customer's premises. Where the current is used for power purposes the mechanical plant is examined, as it has been often proved that much current is consumed or rather wasted in driving badly-erected and ill-lubricated shaftings. A leakage test of the wiring is also made to determine any loss in this direction. In addition to its regular inspection work, the Company for a slight charge undertakes the weekly inspection of motors and thus relieves the customer of burden in this respect.

One of the many other interesting features of the work of this department is the system of card indexes systematically registering the great variety of details of the Company's business. A card index of customers gives on each card the full data as to each customer's installation; this is supplemented by a card index of work in progress, showing by the arrangement of the cards in separate trays, the exact status of each installation which is to be connected to the Company's system—which cards fall into place in the customers' index when the work is completed. The entire city within the limits of the Edison system is mapped on another set of cards, each of which is to record the data as to the houses on each block-face and their relation to the Company's underground system. This is paralleled by another card index showing the data relating to the street mains on each block-face, including their electrical capacity and condition.



VIEW IN WEIGHING ROOM OF METER DEPARTMENT.

For some years electricity shared with "rats" and "spontaneous combustion" the responsibility for fires of unknown origin, and the false notion of danger from fire thus arising led to the keeping of a card index of fires by the Edison Company which gives a report of every fire in buildings within the electrical district, which has resulted in showing how few are the number of fires caused in any way by the electric current. A comparison of this record with fires caused by gas or matches would be interesting.

We might fill several pages describing these highly interesting records, which mean so much for the present

as well as the future development of a Company of this nature, but we must content ourselves with mentioning but one more feature, the General Survey, which was completed within 1895, and which was undertaken in order to enable the Company to know the lamps; the number and make of motors, their horse power and the uses to which they are put; together with other information of like nature. It must be evident that the making of such a survey of a system embracing nearly 7000 customers entails a heavy expense, but the information

exact extent and condition of its customers' installations. What this survey shows can be demonstrated in no better way than by the form appearing on page 47, which gives the record of the Metropolitan Opera House installation in New York, the current for all purposes in which is furnished from the Company's mains, constituting without doubt the largest installation of this kind in the world, supplied from a central station. As the form shows, tests are made of the insulation of the system, nature of conductors, switches, sockets, etc., number of lamps of different candle power, and their equivalent in 16 c. p. it places in the hands of the Company is well worth the outlay.

THE ENGINEERING DEPARTMENT.

A company which is so rapidly extending its work naturally requires an engineering staff and the constant keeping of records of its work. The Engineering Department, with its Bureau of Maps and Records, is located on the eighth floor of the building; a view of one of the rooms is given on page 45. Here all the designing and engineering of the company are carried on and all con-

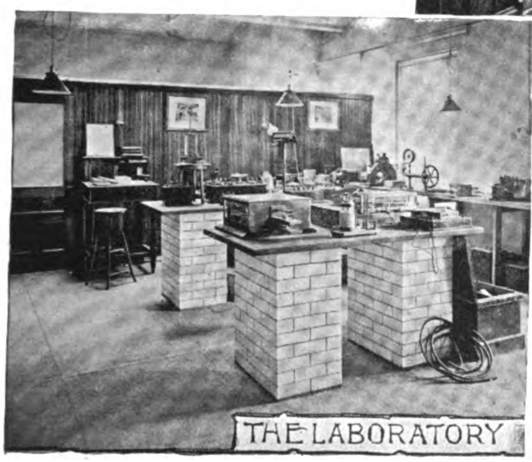
struction records kept, together with those of the laboratory which forms a part of this Department.

An excellent system of maintaining the maps of the distributing system up to date is here employed. It is frequently necessary to furnish blue prints of these maps both to the public and to wiring contractors and as changes occur almost every week it would be a matter of no small import were it necessary to make a new tracing whenever a change occurred. This has been very neatly obviated by the employment of a process patented by Mr. J. C. Elder of the Company's engineering staff. The blue prints are made from a glass plate which is covered with an opaque solution. The city map together with the existing distribution system is traced on the plate by means of a stylus which scrapes away the opaque surface, thus leaving the plate as a direct positive from which blue prints can be made. Whenever a line is extended it only becomes necessary to scrape away the opaque surface from the plate; or, on the other hand, should a line be abandoned or a change made, by painting over the existing line the trace will disappear. This process has given the greatest satisfaction and has been adopted by several large electric light companies for similar work.

In this department also there is kept an elaborate system of street locations on maps drawn to a scale of 25 feet to the inch, which show the location of every tube connection and junction box in the Company's entire system.

THE LABORATORY.

In a company, the success of whose work depends so largely upon the maintenance of constant pressure upon its system, and on the other hand which employs so much auxiliary apparatus, it becomes a matter of vital importance to maintain the accuracy of its indicating instruments and to test all apparatus submitted to it by manufacturers. For this purpose there has been equipped a laboratory, the principal function of which is to keep standard and in repair all the electrical measuring instruments of the Company. It also loans to the various departments testing apparatus needed by each and, in addition, carries on the testing of incandescent and arc lamps and other miscellaneous work, being equipped with a photometer room for that purpose. Among the standard apparatus here used we noticed two Kelvin balances one of 2,500 amperes and the other of 250 amperes capacity, besides a full complement of standard galvanometers, resistances, etc. The work of this department will be appreciated when it is stated that it is required among other things to keep standard no less than eighty portable Weston ampere and volt meters of various types in use by the inspectors and in the various departments of the Company.



THE LABORATORY

MAIN OFFICE HALL

METHOD OF KEEPING ACCOUNTS.

Interesting as it is to follow out through their various ramifications the details of the numerous technical departments and the working apparatus of the Company, nevertheless the statistical work of the Accounting Departments presents features of no less importance and value, especially to central station managers. If a canvass were made of the central stations operating in the United States at the present moment, it is doubtful if one in a hundred would be found to possess the data requisite to determine exactly what each part of the work of generating and distributing electric current costs; and yet this knowledge is most essential and indeed the first requisite as a guide to improvements and increased economy. The New York Edison Company has carried out this work in a manner not excelled by any similar organization in the country, in proof of which we need only refer the reader to the tabular arrangement shown on the page following, which gives the various items into which the accounts are subdivided. These details are grouped under the heads of "Operating," "Construction" and "Ledger Accounts." The first of these, "Operating," occupy the first six columns. In the four succeeding columns, we find the Construction and Ledger accounts, similarly subdivided. It will be noted that the decimal system of classification is employed, similar to that used in connection with The Electrical Engineer Data Sheets. Thus each of the ten main divisions in the three departments, is designated by a single digit ranging from 0 to 9. Each sub-division under any particular division is then designated by two digits, the first of which is the one designating the main division. Where it is necessary to again sub-divide, a third digit is added. Thus an item numbered, let us say, 433, would at once be recognized as relating to the renewal of incandescent lamps in the division of "Distributing Maintenance."

BUREAU OF MAPS & RECORDS

The minuteness with which this scheme has been carried out as exhibited in the schedule on page 46 must command general admiration. Its faithful maintenance makes it an easy matter to determine at any time the exact working condition of the company.

Among the reports furnished from each station is that shown in blank form on page 48, which gives the details of the operating department for each week.

These reports, together with others which the limits of space forbid us to describe in detail, enable the tabulation of the monthly statistics of cost reduced to the basis of the kilowatt hour. With such a form filled out, before him, the Executive can trace the work of the station month by

month and note the effect of any change due to management or to improved apparatus installed.

ADMINISTRATION.

From what has preceded, it is evident that to maintain in proper working order an organization having such important public functions and involving such a mass of detail requires most exact and complete administrative organization. It is safe to say that in this respect, the New York Edison Electric Illuminating Co. is not surpassed

the offices of the Secretary and the Assistant General Manager, and on the eighth floor the Council Room, etc. It is intended that this part of the building shall be fitted electrically like a private house, so that the visitor will find here the various electric features, on the most improved plan, of a modern residence. A library of electrical books and an electrical kitchen will be among the features.

As the visitor enters the central hall, which is illustrated on page 45, he finds immediately to the left a bureau of information where the attendant receives messages and

CLASSIFIED INDEX OF OPERATING, CONSTRUCTION AND LEDGER ACCOUNTS.

by any similar corporation in the world. The General Offices are located on the 7th and 8th floors of the Duane St. Station, on either side of a two-story central hall, reached at the seventh floor by a Sprague electric elevator from the Duane street entrance. This hall is lighted from above by a huge skylight which at night will ultimately be an illustration of one of the applications of arc lighting. It is separated from the Duane street front and from the north end of the building by fire walls to prevent the spread of possible office fires beyond the place of origin. The Executive offices occupy the space between the south wall and the Duane street front, comprising, on the seventh floor, the private office of the First Vice-President,

properly directs the customer or visitor. The offices on the right are those of the Fiscal or Accounting departments, those on the left of the Technical departments,—in each case the officials and representatives of the Company with whom the public has to do being found on the first floor, while the clerks and others handling the routine internal work of the Company are on the gallery floor above their respective departments.

The Treasurer and Auditor occupy at the right a room which gives entrance at the one end to the adjoining Cashier's room, where all money is handled and which cannot be entered except through the Treasurer's room, and at the other end to the fireproof vaults, which are

ingeniously placed next to the great chimney-stacks, so that they are kept warm and dry, utilizing a space which would not easily serve for other purposes. On the gallery floor immediately above, reached by a private stairway, is the Book-keepers' room, with its considerable staff, adjoining which is a smaller fireproof vault, above the other vault, for the books of account and for the payment vouchers, which are so kept that any payment in the past two or three years may be verified at a moment's notice.

On the left the offices are occupied successively by the Controller, who has charge of the purchases of supplies, the working orders for the technical departments and the meter bureau; the General Inspector, who has charge of most of the relations with customers; the General Operating Superintendent, who is in general oversight of the stations, and the Installation Superintendent, who is responsible for the underground system and other construction work; these offices being arranged so that those departments having most to do with each other are in contiguity, while all of these departments can be reached from the Executive offices and from one another without going into the public hall.

Above these offices, as indicated, are rooms for the Correspondence Bureau (stenographers and type-writers), the inspectors, the engineering staff, etc. The Meter room,

REMARKS AND SKETCHES ON OTHER SIDE.

ANNUAL SURVEY REPORT.

Laboratory, Photometric dark room, etc., occupy the gallery floor beyond the north wall.

All these arrangements are planned to facilitate the utmost economy of time and administration, and the several departments are connected with each other by private telephone, as well as with the other stations by private wire from the General Operating Superintendent's room and with the outer world at large through the telephone exchange.

An interesting and novel feature has been planned for the General Operating Superintendent's room, in the shape of a control board which will give within sight of the General Operating Superintendent at his desk, by means of telemetric instruments, the station load, the pressure on the main 'bus or standard feeder, the steam pressure, the amount of coal as weighed by the weighing chutes, etc.

FEEDER TEST REPORT.

A tel-autograph may also be installed by which the other stations may be able to register their data graphically from time to time before the eye of the General Operating Superintendent.

THE STAFF COUNCIL.

One of the interesting features of the Company is the "Staff Council." This body, composed of all the heads of departments, both technical and fiscal, meets every Friday at luncheon under the chairmanship of the Executive head of the Company, and its discussions cover the whole range of the Company's work. The "Staff Council" constitutes, as it were, an advisory board to the Executive, who calls upon it for information to guide him in the management of the Company's affairs.

It includes the Secretary, Mr. Frank Enos, the Treasurer, Mr. Joseph Williams, the Auditor, Mr. H. M. Edwards, and the Controller, Mr. Charles S. Shepard, and the technical staff, viz.: the Assistant General Manager, Mr. John W. Lieb, Jr.; the General Operating Superintendent, Mr. H. J. Smith, with his two District Superintendents, Mr. H. A. Campbell and Mr. W. I. Donshea; the Constructing Engineer, Mr. John Van Vleck; the General Inspector, Mr. Arthur Williams, and the Installation Superintendent, Mr. Henry Stephenson—as also, representing the high-tension companies under Edison control, their General Manager, Mr. Edward A. Leslie.

RELATION TO EMPLOYEES.

The relation of the Company to its employees is also indicative of the care which the management bestows on this important branch of its service. The harmonious relations which exist between them is evidenced by the fact that, with but a single exception, (the case of a

small proportion of employees in its former Wiring Department, who felt bound to take part in a general strike against wiring contractors)—not a single strike or dispute has ever risen between them. Though no regular coöperative system of profit sharing has been established, a beginning has been inaugurated in that direction by the establishment of a system of benefits given to employees at Christmas time. These

payments are graded according to length of service and are figured at one per cent. of the yearly wages to employees who have been in the Company's service for one year; two per cent., for those who have served three years, and three per cent., for those who have served five years and over. It has also been the practice for the Executive to issue at New Year's time a circular letter addressed to all the employees, in which the thanks of the Company are conveyed for past meritorious services, and the aims to be striven for and the things to be avoided are pointed out.

The spirit of the administration of the Company is fairly illustrated by sentences in the Holiday letter of 1895–6: "This great corporation is wholly dependent on its good service to the public for its continuing success, and the Edison badge should be an assurance to the public of good sense, good service and good manners. * * * It has been gratifying to receive during the year expressions of appreciation from customers and the public of courtesy

and satisfactory treatment on the part of Edison employees."

CONCLUSION.

The ultimate authority of the Company is vested by its stockholders in a Board of Directors consisting, besides Mr. Edison himself, who has, however, of late years devoted himself chiefly to other lines of electrical development, and President Trask, First Vice-President Bowker and Second Vice-President Peabody, of Messrs. C. H. Coster, Charles E. Crowell, W. E. Glyn, Arthur C. James, D. O. Mills, W. A. Read, F. S. Smithers, of New York, and Mr. A. A. H. Boissevain of Amsterdam and London. Several of these gentlemen have been connected with the Company for many years and to them are largely due the financial support and the direction of large questions of policy which have made the New York Edison Company what it is to-day.

EDUCATIONAL.

ELECTRICITY AT THE YOUNG MEN'S INSTITUTE, NEW YORK

The evening classes at the Young Men's Institute, 222 Bowery, New York, report a large enrollment this season. One of the most popular is the class in Electrical Engineering, under the tutorship of Mr. R. H. Mansfield, Jr., of the Carpenter Enamel Rheostat Co. The enrollment in this class includes workers from all fields of the practical application of electricity. They are taught the fundamental principles of the science and also its latest developments. By means of text books, lectures, and some experiments, a comprehensive view is given of the whole subject.

Other subjects taught are the commercial branches: Arithmetic, Bookkeeping, Shorthand, English Grammar, and technical branches: Carriage Drafting, Steam Engineering, Architectural Drawing, Mechanical Drawing, Freehand Drawing. Some of these require a two and some a three years' course. A new term began Jan. 2nd, 1896. Young men between the ages of 17 and 25 may enroll at any time.

CONGRESSIONAL ORATIONS BY PHONOGRAPH AND TELEPHONE.

Congressman Smith's oration by phonograph is a happy idea. It fills a long-felt want, says the *Philadelphia Ledger*, by demonstrating how a Congressman may address his constituents in a distant city without neglecting his duties at the National Capital. He makes his speech into the receiver of a phonograph, ships it to its destination by express, and there the instrument delivers it by means of a megaphone attachment. Perhaps, in case of emergency, the telephone could be employed for still more direct delivery of Congressional eloquence. It might even be used to enable every constituent to hear his Representative's speeches as they are uttered on the floor of the House, just as it is to convey the strains of orchestral music in Mr. Bellamy's glimpse of the future. Great are the triumphs of modern science.

Society and Club Notes.

NEW YORK STATE ELECTRIC LIGHTING ASSOCIATION.

As the result of the endeavors of a number of public spirited men interested in electric lighting, notably Mr. C. R. Huntley, of Buffalo, ex-president of the National Electric Light Association, a new organization was formed at a meeting held in this city last week representing already some 34 local companies. The new body adopted the title of the New York State Electric Lighting Association, and formulated its constitution, closing its labors by electing the following officers:—C. R. Huntley, of Buffalo, president; M. J. Brayton, of Utica, secretary-treasurer. The executive committee is now being formed, and will be announced later, but the influx of new companies to membership has a little delayed decision on all the details of that nature. The Association is meeting with the warmest support among the local companies of the State, and the indications are that there will be very few not included within its membership.

CONNECTICUT ELECTRIC LIGHTING ASSOCIATION —ANNUAL MEETING.

The annual meeting of the Connecticut Electric Lighting Association was held at the office of the New Haven Electric Company on Dec. 27, the meeting being called to order at 10:30 by the president, James English, of New Haven. The report of the treasurer, A. M. Young of Norwich, was read and accepted. The next business in order was the election of officers for the ensuing year, and resulted as follows: President, James English of New Haven; first vice president, C. H. Merritt of Danbury; second vice president, L. F. Curtiss of New Milford; treasurer, A. M. Young, of Norwich. directors for two years, J. E. Sewell of Waterbury, A. S. Hurlburt of Norwich. E. S. Breed of New Britain and Charles D. Sherman of Meriden were appointed a committee to draft suitable resolutions on the death of the late James A. Hadley, superintendent of the Meriden Electric Light Company, and first vice president of the association.

On the suggestion of Mr. Young it was decided to hold an outing in June at some of the near shore resorts.

A. J. Purington, superintendent of the Stamford Gas and Electric company; Charles D. Sherman, superintendent of the Meriden Electric Light company, and John E. Sewell, general manager of the Waterbury Traction company, were appointed a committee to prepare a joint paper on various matters of interest pertaining to electric lighting, to be read at the June meeting. After adjournment the members accepted President English's invitation to inspect the new office building and testing rooms of the New Haven Electric Company. Lunch was served at Traeger's.

Legal Notes.

SUIT BY CUSHMAN AGAINST THE CUSHMAN TELEPHONE CO.

Sylvanus D. Cushman, inventor of a telephone, and his wife, have brought suit in the Superior Court, Chicago, against the Cushman United Telephone Company for $250,000 damages. The company was organized a year ago, and has a capital stock of $20,000,000—on paper. Cushman surrendered his patents to the company, which was to manufacture telephones, construct lines and establish exchanges. This, he claims, has not been done, and he wants his property again and damages.

FURTHER DELAY IN THE GOVERNMENT TELEPHONE CASE.

At Boston, on Dec. 30, Judge Colt, in the United States Circuit Court, allowed the United States until May 31, 1896, in which to take evidence in rebuttal in the case of the United States *vs.* the American Bell Telephone Company and Alexander Graham Bell, in which the question of fraud in procuring the Bell Company's patent is raised. Judge Colt refused to limit the Government to the question of fraud raised.

Obituary.

ALFRED ELY BEACH.

The death is announced of Mr. A. E. Beach, son of Moses Y. Beach, founder of the *New York Sun*, and himself for the last fifty years active in the proprietorship and management of the *Scientific American*. Mr. Beach was not only a distinguished technical journalist, but an inventor of considerable ability, his pneumatic elevated railway and his hydraulic shield for tunnel work being familiar instances. He was greatly interested in the black race, and after the war founded the Beach Institute at Savannah, Ga., for the education of freedmen. He was 70 years of age.

Personal.

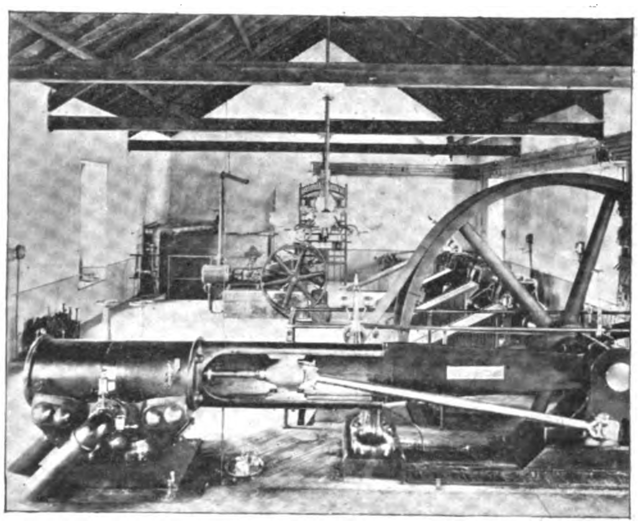
MR. J. H. FINDLAY.

J. H. Findlay.

We present herewith the portrait of Mr. J. H. Findlay, of Ogdensburg, N. Y., who has just been elected to the Executive Committee of the newly organized N. Y. State Electric Lighting Assoication. This gentleman, who is very well known in the lighting field in America, began his career in the gas business about 30 years ago, serving an apprenticeship with his father in Scotland. When he arrived in America the first gas works he took charge of was at Canton, Ohio, where he acted as Supt. and Engr. for 8 years. He went from there to Akron, O., in the same capacity remaining there about 8 years. He rebuilt the gas works at both Canton and Akron. From Akron he went to Ogdensburg 22 years ago and assumed the management of the Ogdensburg Gas Works, which he remodeled and rebuilt.

About 8 years ago, seeing that electricity had come to stay, he added an electric light plant to the gas works, costing over $50,000, erecting a stone building, installing dynamos of 160 arc light capacity, of the Wood type, and a 750 Slattery incandescent using Wheelock and Payne condensing engines for power. During these 8 years he has had excellent success in furnishing electricity, not burning out an armature in that whole period.

About 14 years ago in connection with the above work, Mr. Findlay assumed the management of the Malone Gas Works, and about four years ago consolidated with it a company owning an electric light plant in the town, combining the gas and electric light interests and added a coal business. He also built a very fine new electric plant on the site of the gas works, which cost $25,000, erecting a 2-story brick building, and installed therein Thomson-Houston arc dynamos of 75-light capacity, two 750 Slattery and 500 Thomson-Houston incandescent, with a new



View in Ogdensburg, N. Y. Central Station.

Hamilton-Corliss condensing engine of 300 H. P. Mr. Findlay holds the controlling interest in both the Odensburg and Malone plants.

Mr. Findlay is in the prime of life, active, energetic and enterprising but conservative; and will make an active officer of the new Association of which he is one of the leading spirits.

Mr. B. E. Greene informs us that he has ceased to be editor and publisher of the paper called *Electricity*.

VOL. XXI. NEW YORK, JANUARY 8, 1896. No. 401.

CONTENTS.

1—401.

THE present issue of THE ELECTRICAL ENGINEER is No. 401. The first number of this paper appeared January, 1882, when there was no other electrical paper in existence in this country. In entering upon its fourteenth year, the ENGINEER looks back upon a career of useful existence and of steady growth, through periods of public prosperity and adversity, and it believes itself to be to-day in a position of stability and influence that will enable it to do even better work in the future than it has done in the past. As to the actual facts, the ENGINEER would like to point out that while its first monthly issue contained only 16 pages, all told, the present weekly issue contains no fewer than 88 pages. It may also be noted that the issue this week is mainly devoted to a description of the work of the New York Edison Co., the article with supplement running a length of practically 28 pages. This is the fullest and most complete article ever printed on central station work, and the ENGINEER hopes that it may be regarded as an evidence of its determination to excel as the exponent of electrical engineering in America.

THE NEW YORK EDISON CO.

CONVINCED of the importance of correct design and intelligent operation in electric central stations in order to attain commercial success in these days of close competition, this journal has steadily devoted special attention to the description of modern central stations both in the United States and abroad. For some time past foreign activity has compelled us to go far afield at times in order to place before our readers the latest practice, and it is therefore with enhanced pleasure that we now devote the larger portion of this week's issue of the ENGINEER to the description of what has been accomplished in New York City within the last few years in the field of electric central station engineering in low tension continuous current distribution. The work of the New York Edison Company has a special value to the profession in that it, above all others, represents the evolution from the primitive stage of low-pressure, underground distribution. Indeed when one looks back upon the work undertaken fifteen years ago by Mr. Edison, his coadjutors and assistants,—in an art still struggling for its very existence, and to which were added the unknown complications of an underground system,—one is compelled to admire the courage of those pioneers whose work may be said directly to have sealed the destiny of underground current distribution all over the world. Creditable as was the early work of the New York Edison Company, it is not upon that solely that its claim to recognition depends. Its progressive spirit led it to the construction of the 26th and 39th Street stations in New York which in their day were marvels of economy in space for a given power, and are still excellent examples of central station engineering where the same conditions of high cost of real estate obtain. But it is to the new Duane Street and 12th Street stations of the Company that we would draw particular attention, each of which embodies

a number of features of a highly interesting character. The Duane Street station goes to prove that the days of belting in such large central stations are past; but beyond that we note the adoption of quadruple expansion engines, the first of their kind employed for this purpose in this country.

In thus pointing the way towards higher and better steam engine practice, the Company has by no means neglected its electrical equipment which bears the marks of distinct progress both in the adoption,—we might almost say the creation—in the United States of the multipolar type of central station generators and in the later development of regulating apparatus arranged on the Van Vleck edgewise system. The economy in space effected by the former is admirably supplemented by a similar economy with the latter and we have little doubt that the future practice in this respect will be guided by the example set by the New York Edison Co.

As regards the work of the Company, its record of a maximum of 66,800 amperes for a recent day speaks for itself. The load diagram, which we publish on another page, showing the distribution according to time, is particularly instructive. The curve as there shown has a sharp peak, the reason for which will be apparent on considering the large day or motor load on the Company's mains. At this time of the year, the motor load overlaps and is added to the afternoon lighting load and thus serves to bring up the maximum to a point which it would not reach were these different loads confined to particular and distinct periods of the day. This brings up the question of the limit to which it may be desirable to restrict certain types of load during certain parts of the day or season, in order to avoid the installation of steam and generating plant to meet a temporary load of but very short duration. It also emphasizes the fact that to operate economically, a modern central station must be equipped with apparatus able to carry a heavy overload without danger. This consideration is everywhere predominant in the later work of the New York Edison Company, all of whose material is designed with very large factors of safety.

The most recent work of the Company, that embodied in the design of the 12th Street station, will be watched with keen interest on this side of the sea. The employment of the De Laval steam turbine marks another step towards the adoption of improved methods, the success of which, with the results obtained in English central stations before us, can scarcely be a matter of doubt. So also the extension of its storage battery work places the Company in a position to avail itself of all the benefits which that valuable auxiliary has been shown to bestow upon a system of distribution, more particularly the taking care of the temporary high load of short duration referred to above.

With all these facts before us, we believe it is not putting it too strongly to assert that the New York Edison Co. stands second to no similar corporation in the world in everything that goes to make up a successful system of current distribution. That the progress attained has involved the expenditure of large sums before which a less courageous and enterprising management might have quailed, goes without saying; but surely criticism on that score is disarmed when contemplating the magnificent financial results of the Company and its present capacity for enlarged service. No mention of the recent progress of the New York Edison Co. would be complete without a word of praise for its Vice President and Acting Executive, Mr. R. R. Bowker, to whose energy and executive ability the present splendid condition of the Company is largely due.

THE NEW YORK STATE ELECTRIC LIGHTING ASSOCIATION.

WE are glad to announce that a number of the men prominent in electric lighting matters in this State have got together, on the lines suggested not long since by Mr. C. R. Huntley, and have organized the New York State Electric Lighting Association, with excellent officers and a modest programme. It stands to reason that such an Association can do great good in bringing together for mutual support and the exchange of experience and confidence the men who are most deeply interested in the welfare of the electric light industry and investment. We are glad to know that the Association has already received the active support of a remarkably large number of the local companies, and we would earnestly urge those which have not already joined the organization to take immediate steps to that end. In union is strength, and we need hardly point out the good work that such a body can do for the large and important interest it represents. Every local company should consider it a matter of pride to be in active and sympathetic touch with the Association, as its members, and to do all that is possible to make it a weight and power in the community in promoting the welfare of electric lighting. Other State Associations exist, and their success will prove a stimulus and guide to the new body and its officers, who, we are glad to know, have taken up the matter in a broad, public spirited way and are devoting time and thought to the work.

ELECTRICAL PHOTOGRAPHY THROUGH SOLIDS.

A special cable dispatch from London of Jan. 6 says:—The noise of war's alarms should not distract attention from the marvellous triumph of science which is reported from Vienna. It is announced that Prof. Routgen of the Würzburg University has discovered a light which, for the purposes of photography, will penetrate wood, flesh, and most other organic substances. The Professor has succeeded in photographing metal weights which were in a closed wooden case, also a man's hand which shows only the bones, the flesh being invisible. The *Chronicle* correspondent says the discovery is simple. The Professor takes a so-called Crookes pipe, viz.: a vacuum glass pipe with an induction current going through it, and by means of rays which the pipe emits photographs on ordinary photographic plates. In contrast with the ordinary rays of light these rays penetrate organic matter and other opaque substances just as ordinary rays penetrate glass. He has also succeeded in photographing hidden metals with a cloth thrown over the camera. The rays penetrated not only the wooden case containing the metals, but the fabric in front of the negative. The Professor is already using his discovery to photograph broken limbs and bullets in human bodies.

GOV. MORTON ON ELECTRICITY FOR THE ERIE CANAL.

In his message to the New York Legislature, Gov. Morton says: The recent experiments with electric motors for canal boat propulsion made at the western end of the Erie Canal were so successful in character and results as to lead to the belief that when the system is applied to the entire canal it will increase its traffic capacity by at least 35 per cent. Viewing as a whole the many considerations embraced in this subject, it may safely be suggested that it is one of great importance, and not only merits, but will doubtless receive, your most earnest attention.

PRIZE DESIGNS WANTED FOR THE HANDSOMEST POLE.

The Architectural League of New York announces a prize of $50, to be known as the Avery prize, for the best design of an arc light pole. The competition will be open until Feb. 6.

ELECTRIC TRANSPORTATION.

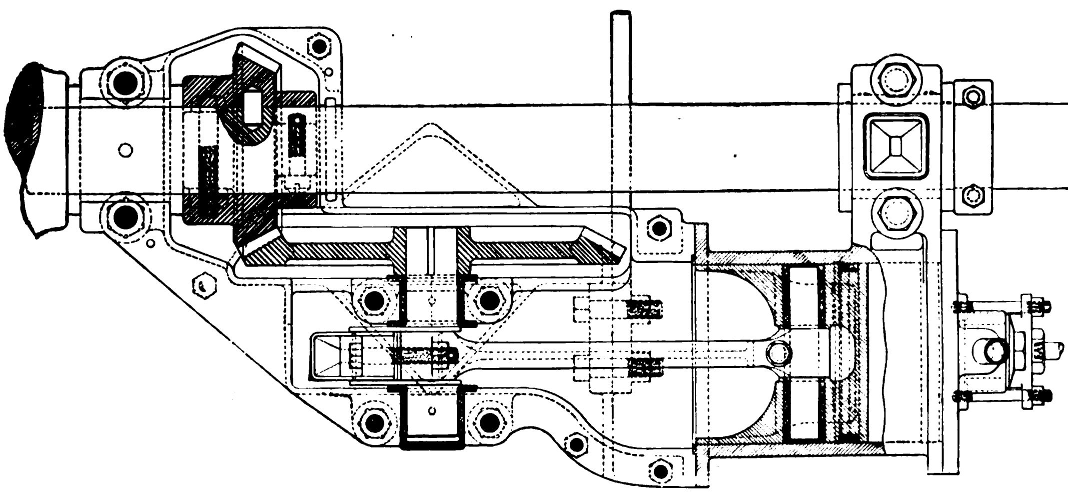
THE NEW STANDARD AIR BRAKE COMPRESSOR.

We illustrate herewith a new and special type of compressor for high speed electric cars now being introduced by the Standard Air Brake Co., whose pioneer and progressive work in this important field of street railway improvement is already so well known.

With regard to the piece of apparatus now presented, it may be remarked, that there are occasions when a company running electric cars at high speed is reluctant to resort to an electrically-driven compressor, on account of cost. In such cases, and where there is a free axle obtainable, the difficulty is met by the use of this geared compressor. Its use will effect a saving in cost over the electrically-driven type.

The construction of the new geared compressor is designed to meet the severe requirements of to-day's practice. The gears are entirely enclosed and they are therefore protected against dirt, slush and water. They are of cast special cut steel ensuring long life. One of the officials of a leading New England road stated recently that their steel cut gears had been running for over two years and showed no appreciable wear. The geared compressor bearings are similar to motor bearings and are provided with ample lubricating facilities.

Another advantage resulting from the use of this geared compressor is the ability to utilize the pony axle on a double truck car, while at the same time the speed of the compressor is brought within a practical limit. By this means the wear and tear is very greatly reduced and it is not necessary for the eccentric to make needless revolutions. For slow speed cars the eccentric encircling the axle answers perfectly. On higher speed cars, however, it is not necessary to have the eccentric throw as often as the increased revolutions make necessary, for it leads to unprofitable wear.



THE NEW STANDARD AIR BRAKE COMPRESSOR.

A noteworthy feature in the geared compressor is the valve arrangement, which renders it possible to unscrew valves without loss of time and to restore them or new ones to place in less than five minutes. It thus becomes unnecessary to remove the car from service in case valves require attention. To admit of increased speed, the valve ports have been enlarged and apparatus designed in various details for this end. The cut does not show the fact that the compressor is meant to be elastically suspended. The supports are flexible, and allow the compressor to meet every condition of swiveling and the upward and downward jolt as well as side play of car body and truck. This means that when the car rides on rough rails, no damage can result to the compressor, as all play is immediately taken up by the new method of suspension. Any jar of the wheels or axles is not imparted to the compressor. In this respect the suspension resembles the latest support of the modern motor.

A special feature of the geared compressor is that there is no chance for the lubricant or oil to escape. This is accomplished by an ingenious arrangement not shown in the cut and the continuous lubrication of crank shaft is also secured. At the same time there is provision made for draining the compressor when it becomes necessary.

This new geared type will be appreciated by managers of high-speed roads who, while realizing the vital need of power brakes, do not feel inclined to pay the increased cost of the electrically driven compressor for the air-brake system. The company is building now, three regular types, viz., an axle-driven compressor for moderate speed cars, a geared type for high speed cars, and an electrically driven type for cars making extraordinary speeds, thus enabling every car in existence to be equipped with an effective air-brake suited to its work.

It is very apparent that the Company's General Manager, Mr. Wessels, is leaving nothing undone to put within the easy reach of every railway manager a thoroughly reliable air-brake. Those who know his executive ability do not doubt his success and cheerfully credit him with highly useful and important pioneer work. The Company is also to be congratulated upon having such an able Superintendent as Mr. Henry P. Merriam, whose well-known mechanical and engineering ability has put him in the front rank in the street railway field.

POWER TRANSMISSION.

TESLA ON ELECTRICITY WITHOUT WIRES.

Mr. Tesla thus writes the New York *Herald* under date Dec. 31:—

In reply to your question as to what discovery would do most to better our condition, in my opinion the demonstration that the earth's electrical charge can be distributed, and thereby electrical waves efficiently transmitted to any distance without the use of cables or wires, would be the most beneficial.

The conveying of motive power from sources such as Niagara in this manner to any place, however remote, would increase many times the productive capacity of mankind. It would bring millions of miserable creatures from the darkness of the coal pits to the light of day. It would cause a kinder feeling to spring up between the weak and the strong, which would lead to a generous adjustment of the evermore difficult questions of labor and capital.

Even if power could not be distributed, the mere transmission of intelligible signals would be of incalculable benefit. Such a realization would do away with the instability of the financial markets, which is the cause of much suffering and misery. It would greatly facilitate the evolution of novel ideas, as well as the prevention of evils. It would increase the safety of travel and give a new impetus to the press and spread of knowledge. The first message transmitted would be the signal to general disarmament and a closer union of nations, and the words of the great German poet, "Seid umschlungen Millionen, diesen Kuss der ganzen Welt," would be deeply felt everywhere.

Our present knowledge is sufficient to fill us with the conviction that the solution of these important problems is not far off. May the new year witness these triumphs.

TO MAKE CHLORATE OF POTASH AT NIAGARA.

Secretary Rankine, of the Niagara Falls Power Company, has announced that his company has made a contract with Walton Ferguson of New York City, under which Mr. Ferguson will erect a factory for the manufacture of chlorate of potash on the lands of the power company and use from 500 to 3,500 H. P. The site selected is to the east of the new calcic carbide plant and covers an acre of ground to start with. The buildings will be put up at once.

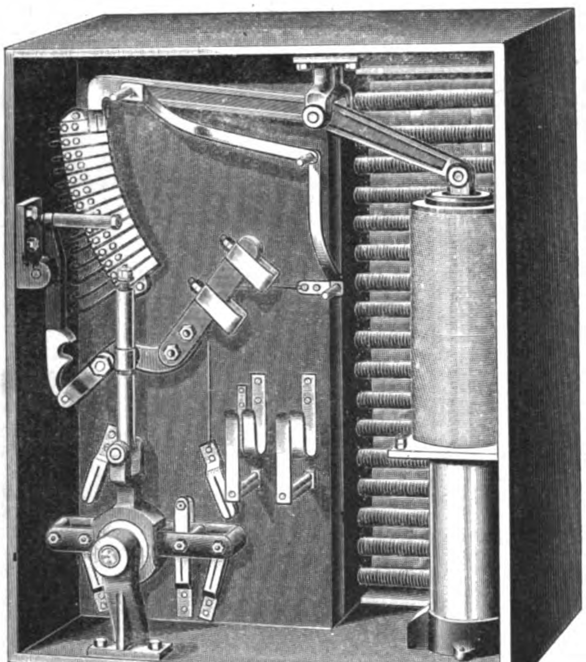
Ricardo Zuloaga, of Caracas, Venezuela, has been at the Falls with Mr. W. B. Wreaks of the Westinghouse Electric and Manufacturing Company to view the power installation there. Mr. Zuloaga is a member of the "Compania Anonima La Electricidad," of Caracas. This company has a project to develop power

from two falls in the El Guaire river, the power to be transmitted to Caracas and used there. One of the falls under consideration has a height of about 120 feet and is expected to give 1,000 H. P., while the other has a fall of 225 feet and will allow of the development of 2,000 H. P. The first fall is only about 10 miles from Caracas, while the second is about 12 miles distant. The lay of the country at the point of the proposed development is such that a surface canal instead of the tunnel method will be used.

THE A. B. SEE ELECTRIC ELEVATOR.

Among those who have devoted their attention to electric elevator work with notable results during the last few years is the A. B. See Manufacturing Co., of 116-120 Front St., Brooklyn, N. Y. The mere coupling of an electric motor to an elevator with a switch to open and close the circuit cannot lead to successful operation. It is obvious that in an electric elevator where the motor is out of sight of the operator, and has to be started, stopped and reversed constantly, often under full load, it is necessary to so arrange a controller that all the current cannot be thrown on the motor suddenly, and so that the switch cannot be left arcing when the elevator is stopped; besides other contingencies that have to be provided for. The controller adapted to fulfill all these requirements used by the A. B. See Manufacturing Co. is shown in the accompanying engraving.

We understand that a suit has been brought against one of the



The A. B. See Electric Elevator Controller.

users of a See elevator on the ground of infringement of a patent which the See Company contends does not contain the slightest hint of the controller used in connection with its elevators. The See Company has, of course, undertaken to defend its customer in the suit. The patent in question was not applied for until December 1884. while Field is well known to have run an electric elevator in 1878, Siemens & Halske in 1881, and Daft, Edison and Sprague had run elevators by electric motors before the patent was applied for. The See Company has sustained its claims of non-infringement by the opinion of such experts as Mr. Edward Weston, Prof. W. A. Anthony and Mr. F. J. Sprague.

SIEMENS-HALSKE POWER TRANSMISSION IN MEXICO.

Manuel Fernandez Leal, Sec. Dep. Fomento, in behalf of the Executive, has entered into a contract with W. Breckman, representing Siemens & Halske, of Chicago, Ill., for the transmission of water power to the city of Mexico from the falls in the municipality of Tenancingo. The concessionaires agree to utilize the hydraulic force produced by the falls of San Simon Atlocomuico and Achayatla for the purpose of generating and transmitting electrical energy to Mexico, the Federal district and neighboring states.

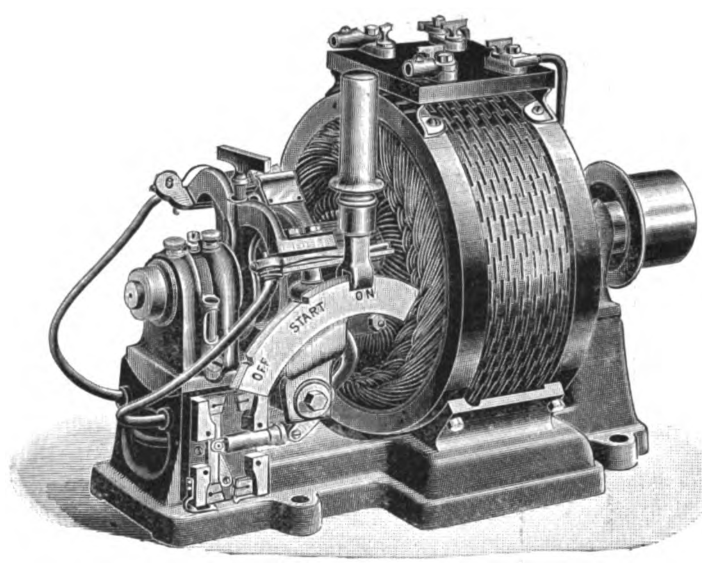
"Enclosed please find draft for $3 to renew my subscription for The Electrical Engineer. I can only say that I am more than pleased in every way with the paper."

Geo. A. Johnston.

THE NEW EMERSON ALTERNATING CURRENT POWER MOTOR.

The Emerson Electric Mfg. Co., St. Louis, Mo., who were pioneers in the manufacture of alternating current fan motors, are now introducing to the trade a line of small alternating current power motors. The ⅛ H. P. size we illustrate in this issue. These motors are non-synchronous, though of practically constant speed, the regulation being within five per cent. between "no load" and the rated capacity of the motor. They are said to possess nearly all the features of excellence of a direct current motor, while being superior in that they, having no commutator in circuit (except while starting), call for no attendance at the brushes. They are protected from lightning by being placed on the secondary side of the circuit, and, being arranged for low voltages, they are protected from the burn-outs due to high potentials and broken wires, which are especially troublesome in 500-volt current motors of small size.

No starting box or other device is required in starting the motor, the stopping and starting being effected by a single lever. This lever moves across a sector (shown in the illustration) with three notches marked respectively, "Off," "Start," and "On." The lever is allowed to remain in the "Start" notch until the motor has attained its normal speed, when it is pushed to "On." In moving to this latter position, the brushes are lifted off the commutator, the external current thus having no connection with the armature winding in this position. The switch and fuse terminals are mounted on the motor itself, the only wiring required with these motors being the introduction of the circuit leads into the terminals. The stock sizes of these motors are made by the



The New Emerson Alternating Current Power Motor.

Emerson Co. for 16,000 and 7,200 alternations per minute, and for 104 volts. Other voltages and frequencies are made to order.

The following are some of the features of merit claimed by the makers for them, the tests having been obtained with ⅛ H. P. motors, and still better results are assured for larger sizes: a starting torque 50% in excess of the running torque; a maximum output of 50% in excess of the rated capacity of the motor; a consumption of energy, running free, of less than 25% of that under full load; an efficiency of from 65% to 80%, according to size and frequency; speed regulation within 5%; a power factor at full load, of 67% on the 130 cycle circuit, and 80% on a 60 cycle circuit, for a ⅛ H. P. machine; and a very slight diminution of torque until the speed has fallen more than 25% below normal, thus enabling the motor to take care of a large temporary overload by virtue of its momentum, and to regain its normal speed afterward. (The inability to do this, is one of the special disadvantages of synchronizing motors.)

These motors are practically noiseless except while starting. They are provided with self-oiling, self-aligning phosphor bronze journals, and a cast steel shaft, the oil boxes being arranged with gauges and cocks, no expense having been spared to make these parts of the motor of the most approved mechanical construction, as indeed they have to be, since the clearance of the armature is a little more than $\frac{1}{100}$ of an inch.

The Emerson Electric Mfg. Co. are putting these out under their usual guarantee, and are finding a ready demand. They have, in preparation, sizes from ¼ to 3 H. P., and are prepared to make prompt shipment on the ½ and 1 H. P. machines of any frequency. Other sizes and a fuller line are promised by them at an early date.

SPRAGUE ELECTRIC ELEVATOR IN THE NEW YORK EDISON STATION.

One of the features of the equipment of the great Duane St. Station of the New York Edison Illuminating Co., described elsewhere in this issue is the Sprague electric elevator which runs from the basement to the offices on the 7th floor.

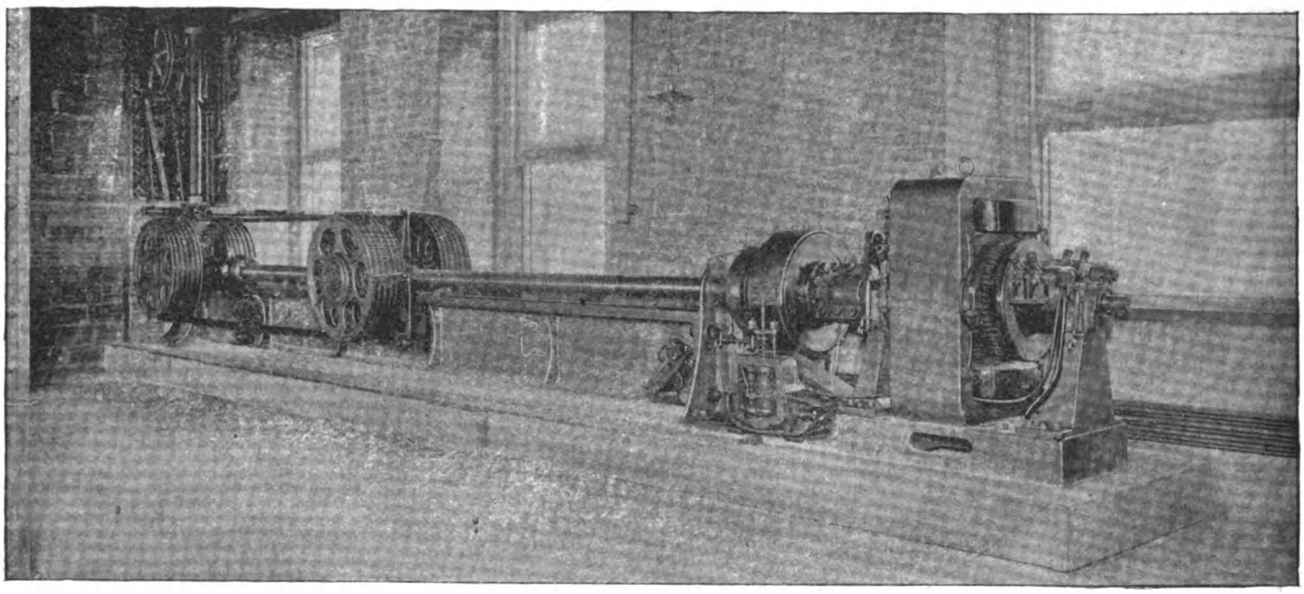
The machine which is illustrated in the accompanying engraving is of the single deck multiple sheave and screw, office building type. It consists of a main bed on which slides a forged steel cross head carrying the travelling sheaves. At one end of the bed is the stand carrying the fixed sheaves, and on the two sets are rove ropes very much as in the horizontal hydraulic tension elevator. The crosshead is moved, in hoisting, by a ball nut of peculiar type operating on a screw directly driven by a motor at the rear end of the machine. The tension on the screw is taken up by ball bearing thrust plates on the back casting, and the machine is locked when at rest by an automatically operating brake.

The elevator is of the gravity type, using power in hoisting, and descending by gravity, when the excess of weight on the car drives the motor as a dynamo. The motor is strongly compounded, and the direction of current is never reversed in the armature or field coils, so that the machine is never demagnetized.

The control is effected by a rheostat operated by a pilot motor, which in turn is controlled by a push-button and an automatic stop lever in the car.

The machine has a capacity of 1,800 pounds, and can drive the car 500 feet a minute. It has all the various automatics, such as upper and lower limits, common to hydraulic apparatus, and, in addition, a centrifugal governor to prevent descending at more than a certain speed, and an automatic control to bring the pilot regulator to a stop position in case the operator lets go his controlling device.

As distinguished from the drum machine, it is the direct rival of the hydraulic elevator for fast service, and is the type now coming into common use through the efforts of the Sprague Company.



SPRAGUE HIGH SPEED ELECTRIC PASSENGER ELEVATOR, DUANE ST. STATION, NEW YORK EDISON CO.

POWER TRANSMISSION AT OGDEN, UTAH.

Rhode Bros., Denver, Colo., are said to have been awarded the contract by the Pioneer Electric Power Co., for the construction of a water power plant. The entire plant will include a dam 450 ft. long, a power house with 10 1,000 H. P. dynamos, six miles of 6-ft. pipe, and is estimated to cost $1,250,000. Work will be begun in the spring. Secy. and Treas., C. K. Bannister, Ogden.

THE CROCKER-WHEELER ELECTRIC CO., Ampere, N. J., have thrown open their factory to inspection on January 15, 16 and 17, one of which days it will be visited by the American Society of Civil Engineers.

JUDGE TOWNSEND, in the U. S. Circuit Court at New Haven, Conn., has heard a motion to reopen the case in which he gave recently a decision in part sustaining and in part voiding the Van Depoele underrunning trolley patent claims.

NEWS AND NOTES.

A MINIATURE MUNICIPAL PLANT FOR PHILADELPHIA.

The Common Council of Philadelphia has virtually provided that a probable balance of $62,000 in the appropriation for street lighting should be set aside to build such a plant.

THE NEW YORK FIRE TELEGRAPHS INVESTIGATION.

With regard to the recent charges made against Mr. J. Elliot Smith, Supt. of New York Fire Telegraphs, that his bureau had been very extravagant, the report now filed by Mr. Callahan as an expert, says:—

"The total amount of cable work done in the years 1888 to 1894, both inclusive, is 463,021 feet of cable laid and connected, 167,661 feet of duct, with pipe, laid and connected, 447 lamp posts, 100 building connections, and the accompanying supply of splicing posts, terminals and flush boxes, service boxes, etc. The average number of conductors per cable is a very small fraction less than nine, and can be called nine. I am prepared to show that the following prices were fair and reasonable: 20 cents per foot for nine-wire cable, laid and connected: 60 cents per foot for ducts built and pipe connected therein; and $35 each for lamp posts placed.

"Applying these prices, we have 463,021 feet of cable laid and connected at 20 cents, $92,604; 167,661 feet of duct and pipe laid and connected at 60 cents, $100,596; 447 lamp posts at $35, $15,645; terminals, flush and splice, and service, $20,000; total, $228,040. The amount expended for the underground cable construction, as shown by the City Auditor's reports during the years under consideration, is $464,000. Deducting the $228,000, as above, leaves $236,000 to be accounted for."

WESTERN NOTES.

THE C. E. WOODS CO. of Chicago, engineers, contractors, etc., in the electrical and other fields have made an assignment. The concern was incorporated last July with a capital stock of $100,000 as a successor to C. E. Woods & Co.

THE WALLACE ELECTRIC CO., 307 Dearborn Street, Chicago, have received an agency from the Adams-Bagnall Co., Cleveland, O., for the sale of their new make of lamps, to which favorable attention has recently been called in the electrical press.

THE ELECTRIC APPLIANCE COMPANY, Chicago, find the new year opening up very satisfactorily for them. Through perseverance and push they have collected a line of first class agencies, which includes bare copper wire, "O. K." weatherproof wire, Packard lamps and converters and Upton arc lamps. In fact a central station man can step into their store (242 Madison St.) and place his entire order for central station equipment, outside of his apparatus. The company have recently been appointed general western sales agents for the Taunton, Mass., Copper Manufacturing Company, one of the oldest and largest manufacturers of copper wire in the country, and are in a position to ship any order for bare copper wire promptly from factory.

TELEPHONY AND TELEGRAPHY.

THE ROUSSEAU "TURN AND PUSH" AUTOMATIC TELEPHONE SWITCH.

ONE of the most recent products of the old established Rousseau Electrical Works, at 810 Mott Ave., New York, is the "turn

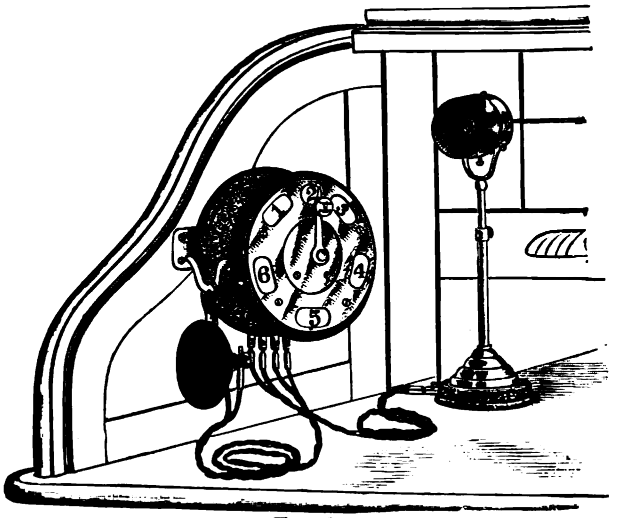


FIG. 2.

and push" automatic telephone switch designed by Mr. D. Rousseau for use in connection with his carbon transmitters. This switch is entirely automatic, dispensing entirely with the central

FIG. 3.

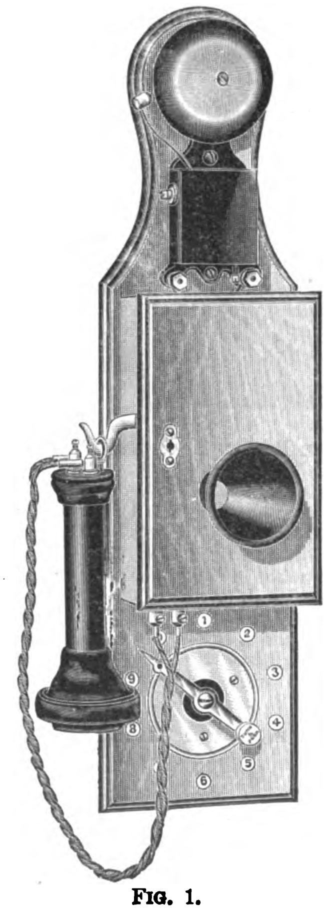

FIG. 1.

station, and permitting one station to talk with any other without interference or interruption.

The engraving, Fig. 1, shows a fancy wall set of this type. When it is desired to call up any station, the pointer on the dial is turned to the number wanted and pressed down, which rings the bell at the station wanted; at the same time a buzzer at the calling end will indicate that the bell is ringing; when it ceases, the caller knows that the other party is ready to talk; he then takes the receiver from the hook, and goes on talking; when through he places the receiver back on the hook, which disconnects all but the caller's own station.

The telephones are arranged to use one set of batteries for call-bells and one set for all the transmitters; but where the lines are long it is advisable to use a separate battery for each transmitter.

The engraving, Fig. 2, shows an automatic switch set, as arranged for desk use, which enables the manager of a business, for instance, to call up anyone in the several departments. It may be of interest to record here that the manager of a large establishment in New York, Messrs. Aitken & Co., employs the Rousseau telephone to dictate his correspondence to a stenographer two floors above.

The Rousseau non-automatic telephone switch set is shown in Fig. 3. With this instrument, when talking is finished, the circuit has to be opened by setting the pointer between any two of the dial numbers; in all other respects the operation is the same as in the automatic switch.

Besides these forms Mr. Rousseau builds a variety of others to meet particular locations and positions, including a telephone exchange battery switchboard for hotels and other similar uses.

A CABLE LINE TO ICELAND.

A GREAT new scheme has been in active progress in London for some time past. It is nothing less than to lay a submarine telegraph line from Shetland, the furthest northern outpost of the British telegraph system in Europe, to Iceland under 500 miles of untraveled sea. The funds necessary for this great undertaking have already been secured, and Great Britain, Denmark, and Iceland will jointly guarantee those who advance the money an interest of 6 per cent. for a number of years. The ultimate success of this undertaking may thus be looked upon as assured.

This news must be hailed with joy by all meteorologists, especially in Great Britain, for whom a daily and regular weather record from a station in the North Atlantic is of inestimable value But England has other interests which have induced her to join in this scheme and bear part of the costs. Her trade with Iceland has been annually growing in volume during the last ten years or still further back, and the time will come when the bulk of the trade of Iceland—which now amounts to somewhat more than $500,000 a year—will be with Liverpool, Newcastle, Glasgow, Dundee, and Hull. It is clear that such a trade will be greatly developed and benefitted by telegraphic communication between the two countries.

There is another aspect of the question, of high importance to a poor country like Iceland. It will bring a stream of tourists into the country, which, though it no doubt will lose some part of its old-world idyllic peace, will be the gainer in the end by increased intercourse with Europe. It is said that the German Emperor has long contemplated a voyage to Iceland in the Hohenzollern, and that it is merely the fact that he could not there be in telegraphic communication with his Ministers which has prevented him from steaming to Ultima Thule, whose sagas he loves and whose grand scenery and natural beauties he is desirous of seeing.

No doubt this telegraph line when finished will open up a new era in the history of Iceland, which, it must be remembered, once upon a time, in the twelfth and thirteenth centuries, took the lead in European literature. Her great past will not return, but there is room for—need for—material progress in the distant island. The telegraph will bring its people within easy reach of European civilization, and they may again recover some of the old glory to which they so often look back with fond regret.

BELL TELEPHONE OUTPUT.

The instrument output of the Bell Telephone Company for the month ending Dec. 20, was normal, although largely in excess of 1894. For the fiscal year the net output has been 94,030, against 17,175 in 1894, 15,980 in 1893 and 39,332 in 1892, so that the year has been a very prosperous one, as far as instruments are concerned. Below are the instrument statistics for the month and the year:

Month Dec. 20.	1894-95.	1893-94.	Increase.
Shipments	14,429	6,472	5,957
Returned	8,073	6,688	1,385
Net output	6,356	1,784	4,572
Fiscal year.			
Shipments	176,060	89,493	86,567
Returned	82,030	72,318	9,712
Net output	94,030	17,175	76,855
Total in use	676,536	582,506	94,030

CONGRESS has been idly discussing the right of the *New York World* to obtain opinions by cable from foreigners on questions affecting American national policy.

Trade Notes and Novelties

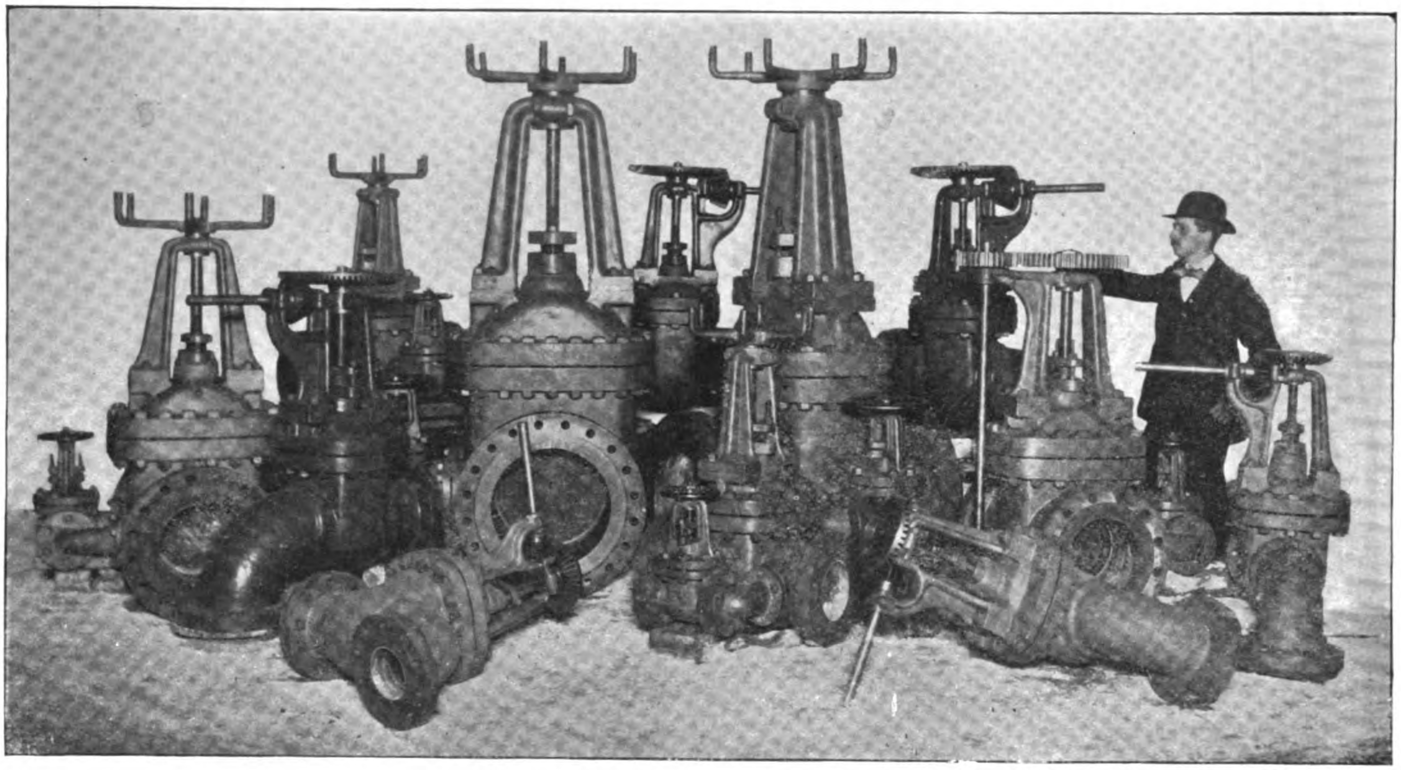
AND MECHANICAL DEPARTMENT.

EATON, COLE & BURNHAM VALVES IN THE EDISON STATIONS, NEW YORK.

In the description of the Edison stations given elsewhere in this issue reference is made to the extreme care exercised by that company in the equipment of its steam plants. This applies as well to the strength of the materials as to their finish and accurate workmanship. The valves which occupy an important place in this department have been carefully looked after, and in the new work of the Edison Co., a number of most important valves were furnished by the Eaton, Cole & Burnham Co., of 258 Broadway, New York, whose works are at Bridgeport, Conn. A group of these valves is shown in the accompanying engravings. The group comprises two 18", one 12", one 10" and two 8" straight way gates, with by-pass, and one 8" and three 6" elbow gates. They are all of the outside screw and yoke pattern, some geared and others provided with spider wheels of the marine type.

In conforming with the requirements of the Edison Company, patterns of hydraulic gates made by the Eaton, Cole & Burnham Company were arranged to suit their specifications. The bodies, bonnets and yokes are all charcoal iron; the seats of phosphor-bronze, and spindles of steel, working on bronze nuts; the discs are cast iron faced with bronze. All joints are scraped and ground, no gaskets being used and the seats are parallel; the gate or disc is double and is straightened by a wedge that strikes a projection in the bottom of the valve expanding the discs firmly against the seats, as they come opposite the pipe opening. The flanges of the 18" valves are 8½" thick exclusive of the ground joint raised faces, and the body is 2⅛" thick; the other valves are proportionately heavy.

All these valves are tested at 400 lbs. hydraulic pressure, and are intended for a working pressure of 250 lbs. The aggregate weight of the group shown, is 26,000 lbs., the 18" valves alone weighing 5,700 lbs. each. They represent probably the finest lot of valves of the kind produced in the United States.



EATON, COLE & BURNHAM VALVES IN THE EDISON STATIONS, NEW YORK.

THE PENN'A INDUSTRIAL REFORMATORY at Huntingdon, Pa., are increasing their electric light plant. They have purchased two 175 H. P. Ball engines built by the Ball Engine Co., Erie, Pa., for the operation of the plant. The Minersville Electric Light Co., Minersville, Pa., are making a number of improvements. They are at present installing a 225 H. P. Erie Ball engine.

THE BARRIETT ARMATURE WINDING CO.

This is the name of a new company just begun operations under the guidance of Mr. S. L. Barriett, whose sole object it is to repair armatures. By concentrating its energies on this business alone, the company believes it will be able to carry on its chosen work to the satisfaction of its customers. None but winders expert in the winding of the various types and makes of armatures will be employed, who will be under the personal supervision of Mr. Barriett, whose long experience in dynamo work is a guarantee of careful workmanship. The company is located at 78 and 80 Cortlandt St., New York.

BAECHTOLD & PARKER ELECTRIC CO.

THE Baechtold & Parker Electric Co., 79 Washington St., Brooklyn, N. Y., are manufacturing a complete line of supplies for all sizes and kinds of American dynamos and lamps, and carry on hand a large assortment of armatures, commutators, brass bearings, brushes, lamps, lamp parts, etc. Their plant has been equipped with special machinery and tools which enable them to fill orders quickly. The Company have a thorough knowledge of, and are especially familiar with. all features and details of the American and Wood arc systems, Mr. Baechtold having had ten years' practical experience with the American Electric Manufacturing Co., New American Electrical Arc Light Co., Standard American Electrical Co., Fort Wayne Electric Co., and Charles J. Bogue. They are also prepared to repair apparatus, rewind armatures, refill commutators, etc., and their facilities are such as to enable them to do first-class work, in short time, at prices consistent with good work, which is guaranteed against faulty workmanship and material.

THE BARNARD WATER COOLING TOWER IN THE TWELFTH ST. NEW YORK EDISON STATION.

One of the features of the new 12th St. Station of the N. Y. Edison Co., is the Barnard water cooling tower used for cooling condensing water. The inventor is Mr. G. A. Barnard and the apparatus was erected by the Wheeler Condenser and Engineering Co., of this city. An illustration of the tower will be found in their advertisement in this issuè, and a detailed description of the apparatus will appear in our issue of Jan. 15.

BOSTON, MASS.—The Lord Electric Co., has been formed with a capital stock of $15,000, to manufacture electric appliances, etc.; Pres., Fred W. Lord; Treas., Thomas P. Curtis, of Boston.

NEW YEAR FESTIVITIES.

To celebrate the close of the old year and the beginning of the new, A. K. Warren & Co. gave their customary New Year's Eve dinner to the employés of the firm,—a practice that has now grown into settled habit with the prosperous young concern. Thee vening at the Maison Francaise passed off very happily and successfully, the dinner being followed by speeches, etc., until 1896 showed above the horizon.

The India Rubber & Gutta Percha Insulating Co. held a reception during the afternoon and evening of the 31st at its downtown headquarters, 15 Cortlandt street. Guests were welcomed by Dr. Habirshaw and by Messrs. Godfrey, Harrington and Olson. The offices were thronged by a goodnatured gathering of wellknown electrical people, and the attendant ambulances were kept waiting a long time.

"Here's Luck" was the brief and characteristic salutation for 1896 sent out by Mr. Charles D. Shain to all who did not drop in to see him and shake hands.

THE GENERAL ELECTRIC TELLTALE DIAL WATTMETER.

In central stations and railway power stations using Thomson recording wattmeters to measure the total output from each machine, or upon each feeder, the grouping of the dials of all the meters in one place where they could be conveniently read at one time has been frequently urged as advantageous. The General Electric Company, has, therefore brought out a "telltale" dial system. This permits the placing of all the dials upon one panel and the installation of the meters out of ordinary reach, as it is no longer necessary to read them each day.

The necessary wiring from the meters to the panel is simple and inexpensive. The panels can be duplicated and the performance of the meters be read either in the dynamo room or in the Manager's office, or any other necessary place, and the performance of the station be accurately learned at any time. Each row

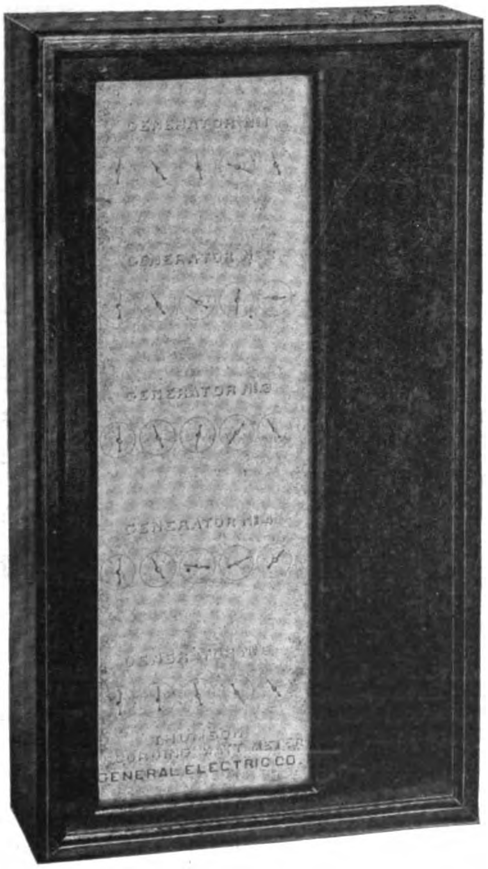


FIG. 1.—G. E. TELL TALE DIAL WATTMETER.

of dials on the panel represents a single generator or feeder, and the recording indicator is actuated every kilowatt hour by a simple make and break device upon the meter measuring its circuit. The dials, one of which is shown in Fig. 1, are several times larger than those on the ordinary meter and they are all direct reading, all constants being eliminated by modifications of the actuating mechanism. It is only necessary in ordering the telltale dial, to state the constant of each meter and the character of the generator, the panel can then be properly lettered.

The introduction of this ingenious telltale system renders the use of a complete system of station output meters possible in many stations hitherto unable to use them on account of the dif-

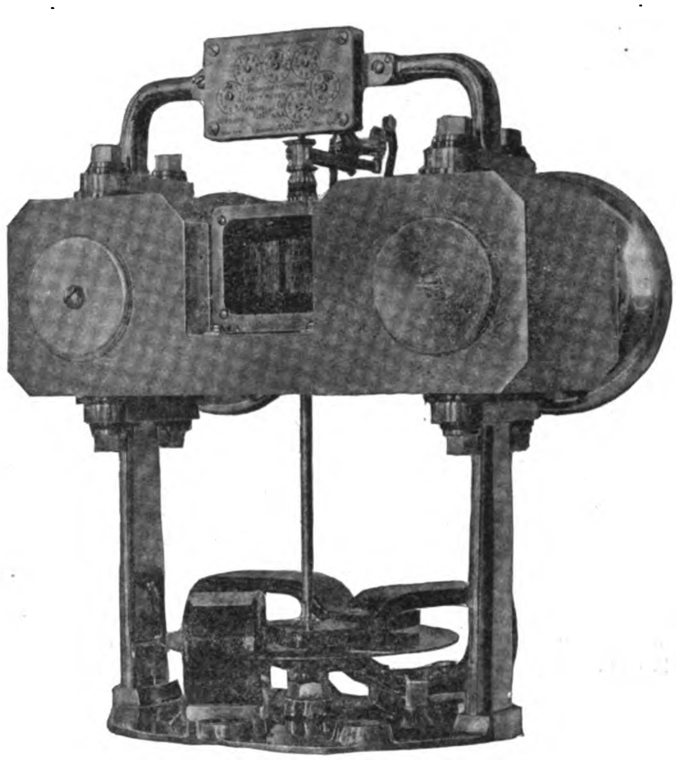

FIG. 2.—G. E. TELL TALE DIAL WATTMETER.

ficulty in installing them, where they can be conveniently and rapidly read.

The station output meters known as "form G," shown in Fig. 2, are constructed upon the same principle as the recording wattmeter, the construction undergoing modification, however, to adapt the instrument to the conditions imposed by extremely heavy loads. They are constructed upon the series principle, the entire current passing through the field, and thus any error and possibility of loss which might result from the use of a high capacity shunt is eliminated.

These meters are adapted for direct application to the switchboard, the studs supporting the meter passing through the board and the bus bars and forming the electrical connection. The conducting parts are of forged copper of the highest conductivity. The three sizes of these instruments, for either 100-volt or 500-volt circuits, are 2,500, 5,000 and 8,000 amperes.

NEW YORK NOTES.

BROOKLYN LIGHTING.—The franchise to the State Electric Light & Power Company has been passed over the Mayor's veto by the Brooklyn Board of Aldermen.

THE TILLMAN ELECTRIC LAMP CO. has been formed with a capital stock of $200,000 to make and deal in electric and other lamps for bicycles, cars, etc. The incorporators are John A. Sullivan, of New York; Jas. Roesler, of Paterson, N. J., and C. J. Henry of New York.

MR. H. H. BROOKS, general manager of the American Circular Loom Co., of Boston and Chicago, was in town recently, and reported that their factory was running day and night to fill orders. Their Chicago office, of which he is in charge, has proved very successful, and flexible conduit, he states, is establishing a good record for itself in the West.

MR. S. F. B. MORSE, of Chicago, of Kerite fame, was in the city this week, and had a chance to see a few of his numerous friends in this city. Mr. Morse is such a generous entertainer in Chicago, that it always affords his Eastern friends pleasure to get an opportunity of reciprocating in some measure, and at least of welcoming him to this city.

THE ALEXANDER SMITH & SONS CARPET CO., of Yonkers, N. Y., have placed the contract for their new dye house building with the Berlin Iron Bridge Co., of East Berlin, Conn. The building is 60 ft. wide and 172 ft. long, the steel roof trusses being arranged to carry cars on the lower chord for moving material about the building.

THE GOUBERT HEATERS AND STRATTON SEPARATORS IN THE NEW YORK EDISON STATION.

One of the most important auxiliaries to a modern economical steam plant is the feed water heater. The accompanying illustration, Fig. 3, shows the type of feed water heater made by the

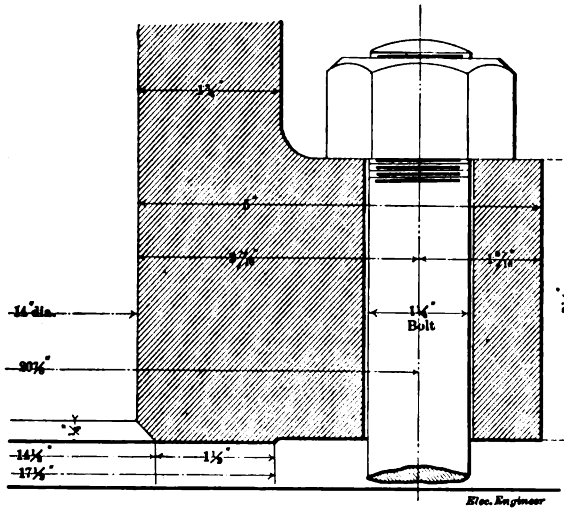

Fig. 1.

Goubert Manufacturing Company of New York, and specially intended for large plants and high pressure. No less than 14,000 horse power of these in units of 2,000 horse power each are

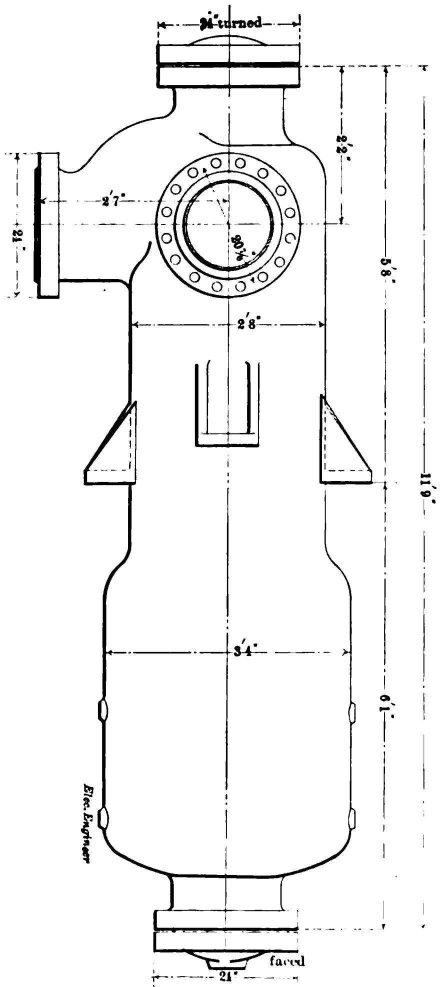

Fig. 2.—Stratton Separator in New York Edison Station.

in use in the various plants of the Edison Electric Illuminating Company of New York, as described elsewhere in this issue.

The Goubert Manufacturing Company has made a specialty of high pressure wosk, and their water-tube feed water heater, as well as the Stratton separator, which is also manufactured by this Company, have been adopted in most of the large electric light and power plants throughout this country.

The Stratton separator, illustrated in Fig. 2, is one of four in use at the Duane Street station and was built to conform to the extremely strong piping system in that plant, as evidenced by the

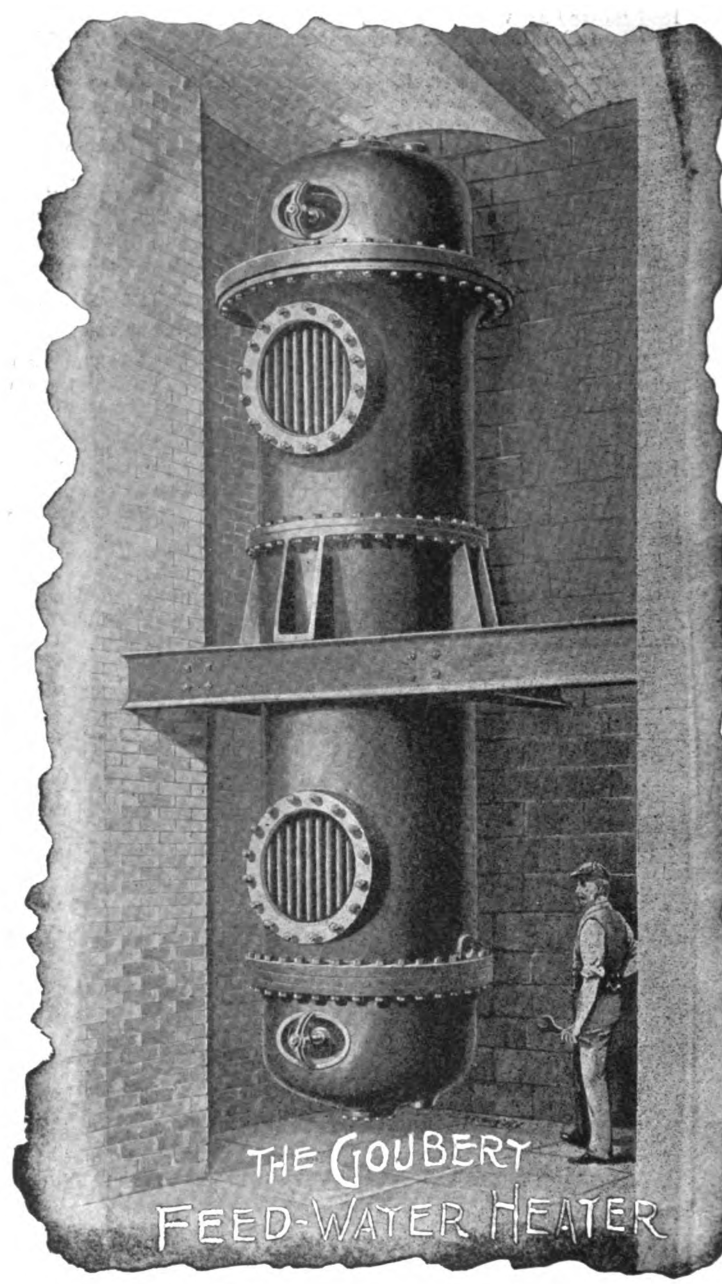

Fig. 3.

sectional view, Fig. 1, which shows one of the flanges, which are 8½" thick. Each separator, which weighs 15,000 lbs., is made of cold blast charcoal iron and was subjected to a test pressure of 500 lbs. per square inch.

WESTERN NOTES.

Dr. H. A. Everett, who since the electrification of the Toronto, Ont., street railway system has been vice-president and managing director, has resigned, in order to concentrate himself on his work for a new trolley system, with cheap fares, in Cleveland.

Stockton, Cal.—The Utica Mine at Angels has suffered so much from scarcity of the local water supply for power, at different seasons, that it is about to begin work on a plant that will be one of the largest electric mining installations in California.

St. Louis, Mo.—Articles of the National Automatic Car Fender Company have been filed in the Recorder of Deeds office. The capital is $125,000, divided into 5,000 shares at $25 each. Charles H. Hofmeister, Jesse A. Graham, Jesse A. Graham, trustee, and D. P. Shields, trustee, each hold 1,000 shares and Henry Moser and D. P. Shields each hold 500 shares.

THE REESE RE-INFORCED COPPER PIPE FOR HIGH PRESSURES.

MODERN electric central station work is approaching more and more to marine practice; this refers not only to the adoption of vertical compound engines direct connected to the generators but to other details, such as the increase in steam pressure and the adoption of devices made necessary in consequence. For connecting the engines with the main steam lines, the best practice now requires the use of copper pipe, but in order to retain its flexibility and still maintain its proper strength some re-inforcing device is required.

Among those who have devoted special attention to this class of work are Messrs. Thomas Reese, Jr., & Co., of 15 to 25 Whitehall St., New York. This firm furnished all the spiral copper banded pipe used in the 26th, 39th and Elm Street stations of the New York Edison Co., and to which reference is made in the article descriptive of these stations, appearing elsewhere in this issue.

The method of constructing this pipe will be understood by an inspection of the accompanying engraving, Fig. 1, which shows a piece of such a pipe in perspective, while in Fig. 2 is shown a section of a 16-inch main used in the Edison Station. As will be seen it consists of a pipe of No. 00000 B. W. G. gauge, around which is wound spirally a band of copper 2" x ½" in section, and to insure uniformity of strain transmission, the spiral band is brazed to the copper pipe.

A special device is employed for making the joint. For this purpose the end of the main pipe carries a heavy copper angle flanged out of solid plate. Seated on this flange is a loose steel ring rolled from a solid forging, in the same manner that locomotive tires are made. This steel ring is drilled for the insertion of bolts for tightening the joint which is made between the copper flanges.

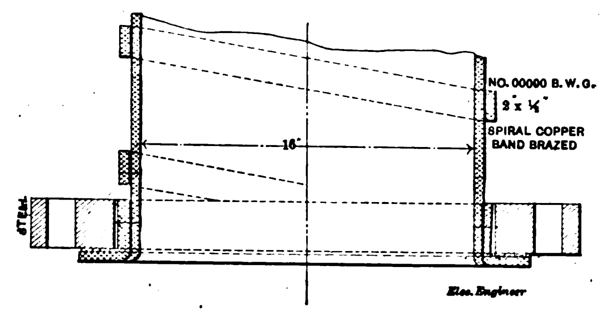

FIG. 1.

Messrs. Thomas Reese, Jr., & Co., who are general mechanical engineers and contractors, also furnished the exhaust pipe and the main smoke flue in the Duane Street Edison station. The former is 32 inches in diameter, and made of $\frac{5}{16}$-inch steel with copper angles and loose steel rings similar to those of the high pressure steam pipe described above.

The main smoke flue is built of ½ inch steel plate, and is so arranged that the air circulates around it and absorbs heat before entering the furnaces under the boilers.

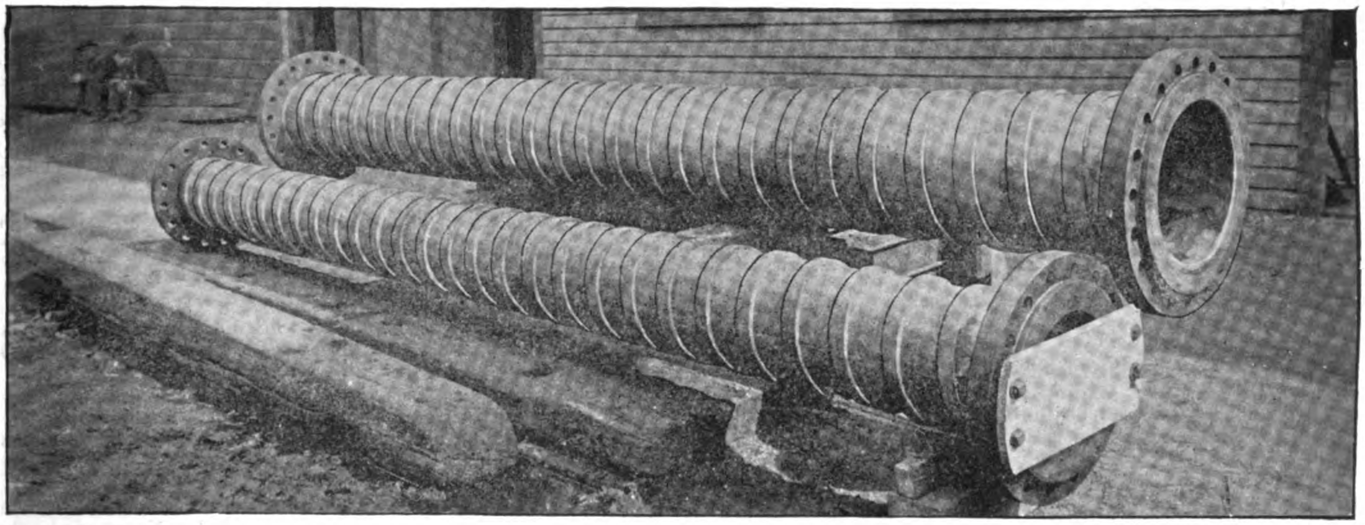

FIG. 2.—THE REESE RE-INFORCED COPPER PIPE FOR HIGH PRESSURES.

LETTERS TO THE EDITOR.

THE CHOICE OF THE TOWN.

The town of Camden, Me., after being in darkness for eighteen months, was again brilliantly illuminated on the ninth of December, much to the delight of the citizens, the ladies being especially jubilant. Manager Hawken of the Knox Gas and Electric Co. has rebuilt the whole line and put in 23 No. 31 Brush double arc lamps, these being the choice of the town.

THOMAS HAWKEN, Mgr.

ROCKLAND, ME.

ASBESTOS AS A HEAT INSULATOR.

WE have received from the McConnell Asbestos Company, Limited, of Pittsburgh, Pa., a pamphlet on "Heat Insulation," read by Mr. John A. McConnell, before the Engineers' Society of Western Pennsylvania. The paper is supplemented by some valuable notes on asbestos, in which the source and purposes of that important heat insulator are described. While asbestos is found in small deposits in almost all parts of the world, its occurrence in commercial quantities is exceedingly rare, the bulk of the entire world's supply being at present mined in the Province of Quebec, Canada, from a little strip of land 3 or 4 miles long, and perhaps a mile wide, or rather from two small patches, one at either end of the strip. There are a few outside mines in Quebec, some of them 30 or 40 miles from the principal deposits, but the output from them is comparatively small. Mr. McConnell, who has travelled nearly all over the United States for the purpose of investigating possible sources of asbestos supply, says he has seen in Wyoming as abundant deposits as in any of the Canadian mines. Lack of transportation is one great obstacle in the way of developing these deposits. There is at present only one railroad near them. But Mr. McConnell looks forward to the time when the United States will be able to fill a large proportion of its own demands in the asbestos trade.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have just completed for the H. W. Johns Mfg. Co., at Brooklyn, N. Y., a new dryer house, which is built entirely of steel.

THE E. T. BURROWES CO., of Portland, Me., are trying to dispose of the 5000 H. P. water privilege of the Saco River at Bonny Eagle, Me., only 17 miles west of Portland and within easy reach of five separate cities.

THE BOSTON ELECTRIC INSULATED POLE COMPANY has been organized at Portland, Me., for the purpose of manufacturing, doing business in and erecting insulated poles upon which wires may be strung, with $100,000 capital stock of which nothing is paid in. The officers are: President, Edward E. Drew, of Boston, Mass.; treasurer, George E. Macgowan, of Portland.

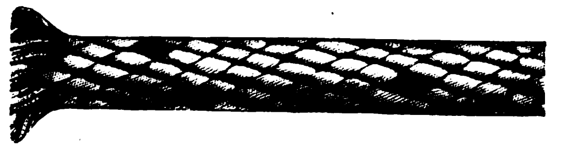
SPRINGFIELD, MASS.—The United Electric Light Co. of Springfield having petitioned for permission to make a bond issue of $200,000, the Massachusetts Board of Gas and Electric Light Commissioners have denied the petition. The Company proposed to acquire 1200 shares of the Indian Orchard Co., which has a broad manufacturing charter and the Commission holds that such an investment would involve new hazards of serious nature, alike to the shareholders and the public.

SAMSON SOLID BRAIDED CORD.

SAMSON braided cord has now become the recognized standard device for the suspension of arc lamps, and it is no less in demand for street car trolley cord and armor cord for covering magnets of dynamos. The size in greatest demand for hanging arc lamps is No. 12 ($\frac{3}{8}$ inch diameter); for trolley cord, No. 8 ($\frac{1}{4}$ inch dia.), No. 9 ($\frac{9}{32}$ inch dia.) or No. 10 ($\frac{5}{16}$ inch dia.); for armor cord, No. 4 or No. $4\frac{1}{2}$ (about $\frac{1}{8}$ inch dia.).

A special waterproof finish is applied, unless otherwise specified. This increases the durability of the cord considerably, and it is strongly recommended for all outside service.

The cord is made of cotton, linen or Italian hemp. The cotton cord is, however, more commonly used, and is probably quite as durable as either of the others. In order to protect their customers against the substitution of low grade cord, the Samson Cordage Works of Boston have undertaken to provide a dis-



SAMSON SOLID BRAIDED "SPOT" CORD.

tinctive mark which will at all times be indicative of first quality cord. They now furnish, therefore, the "Samson Spot Cord," which is their regular "Samson" Cord marked with a series of colored spots. This device they have adopted as a trade mark; and the cord is, as heretofore, warranted of pure stock, perfect braid and smooth finish.

WESTON GENERAL CO.

The formation of the Weston General Company is announced, with Messrs. Edward Weston, F. C. Matthiessen and Henry E. Niese as incorporators, its object being to develop electrical inventions and devices and manufacture and sell electrical machinery and appliances.

Mr. Edward Weston is well known the world over as a distinguished electrical engineer and inventor, and his return to the general field will be universally welcomed. If his new apparatus is as good as his instruments, the success of the Company is a foregone conclusion. It is rumored, though not confirmed, that the new Company will make everything except railway motors. Mr. Weston expects to have his big new factory ready next September.

ADVERTISERS' HINTS.

THE ELECTRIC APPLIANCE CO. has a word to say about "dividend earners" for 1896.

WARREN WEBSTER & CO. note some of the advantages secured in heating by exhaust steam by the vacuum system.

ANOTHER DYNAMO BRUSH has been placed on the market by H. Alex. Hibbard, who carries a full line of electrical supplies.

H. B. COHO & CO. are doing a large business in Eddy direct-connected generators for isolated plants.

AMMETERS AND WATTMETERS are advertised by the Western Electric Co.

OVER 14,000 H. P. of the Goubert feed-water heaters and the Stratton separators is installed in the various plants of the New York Edison Co.

ROUSSEAU'S AUTOMATIC TURN AND PUSH TELEPHONES dispense entirely with a central station. They are specially adapted to a large variety of uses.

THE E. P. GLEASON MFG. CO. will send on request one of their "lightning bug" cut-outs which they hold to be the handiest and smallest fixture and bracket "bug" ever made.

THE EATON, COLE & BURNHAM CO. describe one of their improved pipe threading machines for belt power or engine attachment. They also manufacture a large variety of valves and fittings.

A TABLE OF REVOLUTIONS of slow and moderate speed generators for light and power appears in the announcement of the General Electric Co. in this issue.

THE CALCULAGRAPH CO. continue to advertise their instrument for keeping tab, of which they say "It saves labor and makes no clerical errors."

ELECTRIC RAILWAY MEN will find a great deal of interest to them in the several "ads" of the Standard Air-Brake Co. appearing this week. Under such headings as "Ancient History," "The Handwriting on the Wall" and "How to Win Some Dollars". They discuss questions of to-day in a style quite refreshing and worthy of initiation by other advertisers.

THE C & C ELECTRIC CO. state there are more of their motors installed on the circuits of the Edison Electric Illtg. Co., of New York City, than of any other make.

THE GREGER NOISELESS MANHOLE COVER CO.'s card in this issue shows another style of their covers. Possessing so many decided improvements their universal adoption is assured.

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY CO. show several of their instruments in this number, giving their prices and offering their illustrated catalogue on application.

THE BAECHTOLD & PARKER ELECTRIC CO., manufacturers of the "American" arc dynamos conduct also a repair department and guarantee against faulty workmanship and material.

JAMES G. BIDDLE announces that his "Catalogue X" is the most complete, concise and convenient price list of Weston instruments ever distributed.

NO CENTRAL STATION IS COMPLETE unless installed with "Kerite" wires, according to W. R. Brixey. The demand for them is as large as usual.

THE NEW YORK EDISON CO. have tested and are constantly using the "Electra" high grade Nuernberg carbons, imported by Hugo Reisinger, New York, who carries all sizes, cored and solid in stock.

THE MICA INSULATOR CO. publish a testimonial letter from the Fort Wayne Electric Corporation regarding the very satisfactory results obtained from using "Micanite" for insulating purposes in dynamo and motor construction.

"A STATEMENT OF FACTS."—Under this title the A. B. See Mfg. Co. gives a brief history of the suits brought against it for alleged but indefinite infringement of another company's patents and also illustrate some of their apparatus.

THE STAR ARC LAMP embodies all the latest improvements, is the claim made for it by the Auerbach-Woolverton Electric Co., who guarantee perfect satisfaction to each customer. Their catalogue for 1896 is now ready.

THE INTERIOR CONDUIT & INSULATION CO. calls attention to the completeness of its output for the generation, distribution and utilization of current. Selling on its merits the apparatus is rightly more popular than ever.

THE DICKINSON ELECTRIC SUPPLY CO. are introducing an advertising lamp. Each lamp is a single letter, thus greatly simplifying the construction of a sign, making the cost low and permitting a change in the reading without any trouble.

R. B. COREY'S ABILITY to fill orders for arc lamps and carbons is continually increasing. Lamps in every style and for every kind of service and the renowned Schuyler Nurnberg carbons partially constitute the stock he has to draw from.

THE REESE REINFORCED COPPER PIPE, with hammered steel flange rings is in use in the Edison Company's station in this city. Thomas Reese, Jr. & Co. also make special pipe, valves and fittings for high pressure steam of cast iron and steel.

THE SPRAGUE ELECTRIC ELEVATOR CO. publish a list of buildings in which their elevators are now in service. The length of the list is a good proof of their excellent work. They build them for any speed and capacity.

"WHY NOT HAVE THE BEST" is the question asked by the India Rubber and Gutta Percha Insulating Co., who also say "It would surprise you to know how many miles of our wire carries current to lamps and motors from the Edison Stations in this city."

THE BRISTOL COMPANY catalogues over one hundred different varieties of recording instruments for pressure, temperature and electricity. Parties interested are invited to write for prices and discounts, and to order an instrument for a month's trial with privilege to return if not satisfactory.

WATER WHEELS of from three feet to two thousand feet head for lighting and power plants are manufactured by the Jas. Leffel & Co., who are now constructing four 2,000 H. P. wheels for the Niagara Falls Hydraulic Power & Mfg. Co. Their thirty-three years of business in this line amply qualify them to meet all requirements.

THE NEW YORK ELECTRIC EQUIPMENT CO. assert they have connected more lights, motors, arc lamps, etc., to the mains of the Edison Electric Illtg. Co. of this city, than has any other company. With every facility for doing first class work they should be and are able to give entire satisfaction in all they undertake.

A MAGNIFICENT ENGINE IS SHOWN in the advertisement of the Southwark Foundry and Machine Co., for direct connected service in the station of the Edison Elec. Illtg. Co. of New York. These engines have been found especially efficient for direct coupling and they have installed them in several of the largest stations in the U. S.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

Vol. XXI. JANUARY 15, 1896. No. 402.

ELECTRIC LIGHTING.

THE MARKS VENTILATED ENCLOSED ARC.

THE shortening of the arc for a given drop of potential due to surrounding the arc by an inclosing medium and excluding oxygen, has made it necessary in the commercial operation of inclosed arcs to employ a higher drop per inclosed arc than would be necessary for open-air arcs, for a certain length of arc is required in order to produce a steady light, and in the case of the inclosed arc a greater potential difference is necessary to secure this length of arc than in the case of the open-air arc. This follows naturally from the increased resistance of the inclosed arc. If the attempt be made to operate the inclosed arc at as low-potential drops as open-air arcs, unsteadiness of the light results. Because of the flattening of the carbon points due to being consumed in the absence of an oxidizing agent the light is largely obscured and the illumination effective only in a small zone. Moreover, if operated at as low a potential drop as an open-air arc, the negative electrode invariably builds and a mushroom-shaped formation results. This formation consists largely of graphitic carbon. The nib thus formed breaks off eventually at its neck and flickering and unsteadiness of the light results.

To avoid these difficulties Mr. Louis B. Marks, of New York, whose work in this field is well known, has designed an envelope in which a limited circulation of air takes place, and which is illustrated in the accompanying engraving.

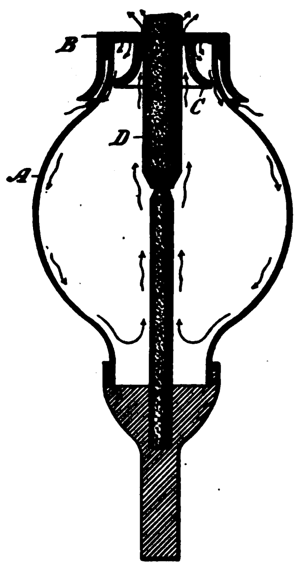
The envelope A is provided at the top with a loosely-fitting cap B touching the cylinder only at four projections in the centre of which is a circular or conical tube C, through which the positive electrode D is fed to the arc. The negative electrode, by reason of its slower rate of consumption, may be smaller in diameter than the positive. The outer portion of the cap is enlarged into a bell-shaped flange, the rim of which is brought closely adjacent to the exterior wall of the envelope. Thus there is provided a narrow annular passage for the outside air into the envelope, one of the walls of this passage being formed by the envelope, which, by reason of its high temperature, heats the entering air in transit into the envelope. The tubular opening through which the electrode feeds is made slightly conical in shape, the enlargement at the top being only a little greater than the diameter of the electrode, so as to permit a free feed of the latter and to afford an obstructed egress for gases from the envelope.

The lower part of the tube is flanged away from the electrode as shown, this form serving as a deflector for the upward currents around the positive carbon, the flange at the same time forming a deflecting-wall for the ingoing air and directing the latter outwardly toward the walls of the envelope. The tendency with this arrangement is for all egress to take place by way of the central tubular opening and all ingress by way of the bell-shaped chamber.

The arrangement of the cap as above described deflects the ingoing air into the downwardly-moving portion of the convection current, where it is intimately mixed with the gases already formed in the envelope and raised in temperature, so that it is intensely hot by the time it reaches the arc.

A highly important result which follows from the distribution of air-currents as described is that the resistance of the arc-stream, instead of being considerably increased, as is the case with other inclosed arcs, remains practically the same as in an open-air arc. The length of arc for a given drop of potential is therefore practically the same as that of an open-air arc of the same drop of potential.

Because of the flow of convection currents of arc-gases admixed with atmospheric air the electrodes do not burn blunt as in ordinary inclosed arcs, but have much the same shape as points formed in open air. The crater formed in the positive is substantially uniform in curvature, while the apex of the negative is quite pointed and well centered with reference to the crater of the positive. Thus there is practically no obscuration of light as in



MARKS VENTILATED ENCLOSED ARC

the usual inclosed arcs where the electrodes burn to blunt points. The light is steady and efficient at practically as low drop of potential as with open-air arcs.

Lamps with this type of envelope can be run at 45 or 50 volts and the carbons have a life of 50 hours.

FALL RIVER, MASS., LIGHTING COMPANIES TO CONSOLIDATE.

THE Edison Electric Light Company and the Fall River Electric Light Company are to consolidate. The capital of the Fall River company, which was recently increased, is $200,000. It has a valuable contract with the city for lighting the streets. The Edison's capital is $150,000. It operates the incandescent lights. Details are not to be made public until legal permission is granted for the union.

THE DETROIT MUNICIPAL ELECTRIC LIGHT PLANT.

BY JAMES I. AYER., EX-PREST. NAT. ELEC. LT. ASSN.

NOTING the recent discussion of the cost of electric lighting in Detroit, I recall the fact that a number of years ago one Whipple, when city clerk of Detroit, at the expense of the city, gathered together a lot of data (which he published in book form, for his own profit), which indicated that arc lights under municipal ownership could be produced for from $30 to $50 per lamp per year. A little later reports from Chicago, derived from about the same experience in operation as from the basis of the statement of the Detroit cost, stated the cost under municipal ownership to be about $50 per lamp per year. As is well known, Whipple's book was ingeniously compiled to tell only a one-sided story and was as unreliable as the author proved to be himself.

As to Chicago, the new Moses who was to lead the taxpayers out of the darkness with the cheap light proved to be a veritable "will o' the wisp" leading them deeper and deeper into the mire of debt from year to year until now the annual cost is more than three times the original figure.

Mr. Dow, with the limited experience of two or three months' operation of the completed plant, with everything brand new, the repairs on most if not all of the station machinery being cared for by the contractors without cost, with all employees doing their best, without the plant being encumbered by the usual accumulation of political barnacles which come in due time, without including any cost for depreciation, for taxes, etc., assumes that the figures derived are the proper ones to put before the public as the cost of producing an arc light, and assumes that with time the cost as shown will not change. Mr. Dow states that the "expensive" and "thorough methods" of maintenance under his "fixed policy" together with the appreciation in value of the real estate will keep up the value of the plant to its original cost so that the item of depreciation should not be considered. It is manifestly absurd to talk about maintaining permanently the value of the first investment without providing a sinking fund for the necessary improvements and repairs. No one believes that a station, no matter how well cared for, that was built ten years ago, still operating the old machinery, has the same value as when it was installed.

The appreciation in value of the ground would have to be something enormous to justify the abandonment of the present site with its expensive foundations, etc. From a recent article[1] published in defence of municipal ownership the following occurs in reference to the lighting plants owned by Chicago, the oldest of which has seen but seven years of service: "Now as a goodly portion of the machinery * * * is no longer looked upon as up to date, that is—suitable, efficient and economical—the factor of depreciation must far exceed the usual allowance. In fact in comparison with some recent installations much of the apparatus owned by the city would bear a strong resemblance to the reported loss that occurred in displacing the cable lines in Philadelphia with electric traction" * * "the machinery at the power station * * represented to the Traction Company an immense amount of money * * hundreds of thusands of dollars * * " and "of all the machinery in the immense plants the engines and boilers are alone valuable above scrap iron." Mr. Dow as a partial explanation for low cost says that service furnished by contractors would have to be extended wherever required whether it was profitable to do so or not, but that he does not intend to take on such service. Such a statement does not require a comment.

A member of the lighting commission states (and an investigation of the figures so indicates) that with 5 per cent. charged for depreciation the present cost is practically at the rate of $100 per year. With this showing now during the first few months of operation what is reasonable to expect as an average cost for the next five years, under municipal management? Mr. Dow, no matter how good his intentions, cannot keep off the political barnacles, any more than he can prevent an increased cost for maintenance in the way of repairs etc., or prevent depreciation.

At present while the new $600,000 plant is barely in operation it is not sufficient to supply the wants of the city, and to meet the additional demands. An ordinance has been introduced which contemplates the expenditure of $150,000 more if the plans are carried out A few years ago, largely on account of improvements in electrical apparatus and steam plants, Detroit was able to effect a radical reduction in the cost of street lighting, under competition between contractors, and since has been enjoying the benefits of lights at very moderate cost. When by reason of proposed extensions the cost of the plant is increased $200,000 or more, and the "expensive lighting" is taken on and the cost of light far exceeds the rates formerly paid by the city, then we shall have another exposition of Chicago's results, viz.: much of the plant out of date and a considerably increased investment necessary to put it in shape to meet the new conditions. Cheap lighting may be possible under municipal control, but it has not been so demonstrated in this country. As has been well said many times before, municipal ownership of lighting plants, after an unprejudiced investigation, only meets with the enthusiastic approval of the ubiquitous politician.

THE CATHODIC RAYS.[1]

BY CH. ED. GUILLAUME.

SINCE we gave an account here of the important work to which the mysterious phenomena of the cathodic rays have given occasion (July, 1894), the attention of physicists has been drawn more than once to their true cause, the partisans of the two theories accumulating since then argument on argument, none of which appears absolutely decisive.

The English opinion, founded on the theory of Mr. Crookes, of a molecular bombardment in a very rarefied gas, defended by such champions as Lord Kelvin, Prof. Fitzgerald and Prof. J. J. Thomson, has recovered ground on the theory of the vibratory origin of the rays which is particularly sustained in Germany. At the base of this latter opinion we find the remarkable labors of Messrs. Goldstein, Autz, Wiedemann and Ebert, and especially those of Mr. Lenard.

We recount the facts. If, in a thoroughly exhausted tube electrical discharges are provoked, glitters (gleams) of a peculiar sort are produced due to these rays propagating themselves in a straight line, and which appear, especially when these rays strike any solid, liquid or gaseous body. Very indistinct in a gas, these gleams become intense on contact with solids, and specially brilliant when the rays fall on certain phosphorescent bodies.

These rays traverse bodies without exception if of less than certain small thickness, and, while their production is intimately bound to a very tenuous state of the matter about the cathode of a Crookes tube, their propagation is effected in any medium whatever. Their presence in the air is obvious several centimetres from the apparatus, after the ray has crossed a metallic septum closing the tube in which they are produced. Starting from the facts put in evidence by Mr. Lenard we were inclined to think the Crookes theory should be abandoned, and in this bias finished our first article.

The errors of the bombardment theory once shown, it seemed relatively easy to explain the phenomenon as a wave motion analogous to that which produces light. Certain bold spirits have dared to invoke longitudinal vibrations of the ether, or radiations of short wave lengths with which certain peculiarities of the rays present striking analogies.[2]

Within a year no one has made a step in this direction whereas several connected facts have impeached the theory of Mr. Crookes in which at any moment an absurdity is liable to appear. We mention here only by way of memorandum an experiment of Mr. J. J. Thomson on the speed of cathodic rays. The eminent Cambridge professor provided himself in order to determine this speed with a mirror turning around an axis parallel to the direction of propagation in the tube, and throwing reflection suc-

1. From *La Nature*, Dec. 21, 1895.

2 This theory has been developed in very ingenious fashion by Mr. Jaumann; but Mr. Poincaré has shown quite recently that the hypotheses of the learned Austrian professor take no account of the rectilinear progress of the rays, nor of their deviation in the magnetic field.

cessively on two screens at the distance of two centimetres. The images reflected by the mirror, and corresponding to the first trace of light produced by the phosphorescence of the screens were in the extension of each other so long as the mirror was quiet, but were distinctly parted when the mirror was rapidly turned.

It may be concluded from this that the propagation of the rays takes place with a finite velocity as is deduced from the displacement of the images. The measures of Prof. Thomson give a speed of 200 kilometres a second, a speed which he finds justified, on the hypothesis of bombardment, by the efforts the molecule makes in the neighborhood of the cathode as it carries its electric burden.

It should not be forgotten that the calculation of this speed is founded on the measure of a time interval of one-half a millionth of a second, and that, if the retardation of the phosphorescence of the second screen due to the weakening of the ray in its course, marked this limit, the experiment might just as well lead up to very great velocities, that of light in particular. As any hastening of the phosphorescence of the second screen is inadmissible, as is also any gross error toward the lessening of the time period, Prof. Thomson's experiment only shows that the speed of the rays is very great, incomparably greater than that of the gaseous molecules according to the kinetic theory. This is not an argument against the ideas of Mr. Crookes, as Prof. Thomson indicates a reason for a very great speed; but this rate of motion, 200 kilometres a second, brings no advantage to the theory of radiations while the rate given is out of agreement with what we know of the rapidity of the movements of transmission of ether perturbations.

It is apropos to note the discussion on the absence of the Doppler-Fizeau phenomenon in cathode rays. If the cathode rays are due to matter in motion, say the partisans of the radiation theory, a displacement of spectral rays should be seen agreeing with that seen in the motion of the stars, not a trace of which phenomenon has yet been seen. Lord Kelvin has well said that if one is limited to speeds less than one kilometre a second, as certain calculations indicate, the phenomenon would be at the limit of sensibility of the actual instruments. But this argument does not hold if the speeds are considerable, and the experiments of Prof. J. J. Thomson permit of no doubt in this aspect of the question.

At the same time the cause does not seem desperate. The gleams which are seen may not be due to matter in motion; one always sees them whenever there is shock, in which case it is the molecule in repose, or slightly displaced by the shock which emits the light; in this case the phenomenon of Doppler disappears from the question and there is no room to invoke it pro or con. It is possible some one will see it any day under particular circumstances. It certainly would not have the intensity which the speed found for the cathode rays assigns to it, and the cause of the divergence would be due to the fact that the speed taken by the particles of matter under the influence of shock would be much less than that of the primitive atoms. There are good reasons for believing this is so.

But can one admit that material particles, even thrown with great speed, can traverse solid bodies below a certain thickness, or metallic films not absolutely opaque, and hold their course indefinitely into space? The thing is difficult, but not without a certain degree of probability.

In an experiment already old, Mr. Arons has shown that a very thin metallic septum placed across a trough containing acidulated water is not charged with gas on its faces, and gives rise to no counter electromotive force, while the current is sensibly weakened if this plate is replaced by a thick one with a hole in it far larger than the sum of the visible pores in the metal.

What decision shall we come to, that a molecule apparently broken in pieces by the action of the current passes when it was stopped beforehand? The gas is re-formed across the metal leaf, and since it opposes no appreciable resistance to the current we must suppose it passes with the greatest ease. Besides, gases are easily electrolyzed as bodies in solution, and there is nothing to show that the phenomena, well substantiated in the case of electrolytes, are impossible in the Crookes tubes. All the radiations show selective absorption on the various bodies quite independent of the mass traversed. Metals stop light at a few thousandths of a millimetre in thickness, while one can see the radiations through several hundred metres of water. This is not true of cathode rays which according to Mr. Lenard are absorbed directly according to the mass traversed. May one not conclude that the action is in some sort mechanical? As we see them the facts in this singular phenomenon are contradictory. The hypothesis of bombardment presents gross difficulties, but it adapts itself marvelously well to the above view of the case.

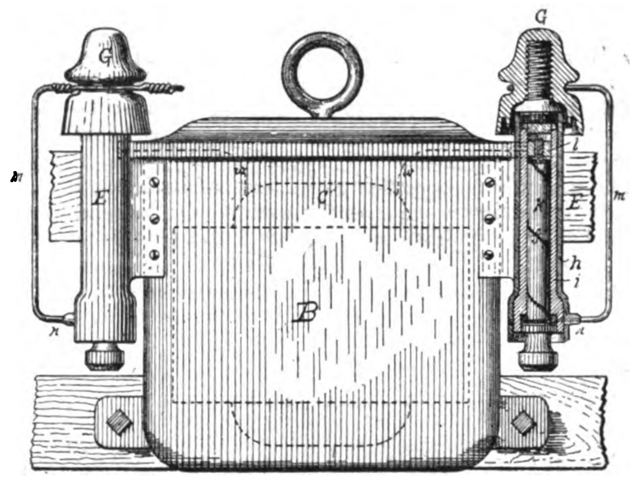
Whatever may be the final decision, the kinetic theory of gases has a new foothold of final proof; but many experiments are still needed before it will get there.

The Gamewell Fire and Police System at Jacksonville, Fla., is said to have been so disturbed by induction from high tension electric light wires that it has become dangerous even to attempt to handle the boxes at times. Mr. A. C. Farrand, agent of the company, has been investigating and rectifying the trouble.

WAGNER AND SCHWEDTMANN'S TRANSFORMER CUT-OUT AND INSULATOR.

Fusible cut-outs for the primary circuits of converters are usually placed on a convenient support near the transformer, and sometimes on the transformer box; but the wires coming from the supply-mains are always supported by separate brackets carrying porcelain or glass insulators, and attached to the wall or support near the transformer. The wires cannot be led directly from the transformer to the supply-mains, as their weight and the strain of the wires would pull them out of the coils. To avoid the expense and inconvenience of thus supporting these devices separately, Messrs. H. A. Wagner and F. Schwedtmann, of St. Louis, have devised a means by which they may all be combined.

The arrangement intended for this purpose is illustrated in the



Transformer Cut-Out and Insulator.

accompanying engraving. Each fuse cut-out consists of an outer metal shell or holder h and an inner shell of non-conducting material i inclosing a removable core k, also of non-conducting material, and carrying a fusible metal strip f. The wires w leading from the primary coil c of the transformer are connected with the terminals l of the fuses f, and make electrical connection through the fuses with the wires m passing out through the insulating bushings n to the insulators G, from whence they are led to the supply-mains.

By the construction adopted, the strain of the wires leading to the supply mains is taken up entirely by the insulators.

PHOTOGRAPHING THROUGH SOLIDS BY ELECTRIC RAYS.

Last week we published a special dispatch from Europe, in regard to the photographing through solids by Prof. Rontgen by means of vacuum tube light. The following dispatch from London of Jan. 11 says:—"Great progress has already been made with Prof. Rontgen's wonderful discovery of a new light, if that be a proper description of it, which I cabled a few days ago. Prof. Klupathy of the Pesth University has obtained even greater success in photographing concealed objects. He also varied the experiments by enclosing objects to be photographed in a variety of coverings. It has been ascertained that the light from Crookes tube penetrates not only organic matter, but also one metal, aluminum. Prof. Rontgen has sent rays of the new chemical light through aluminum plates an inch thick, and they went as clean through as if the substance had been glass. The same was the case with two sets of books, including many volumes, these he placed between a Crookes tube and an ordinary compass. Behind them was a wooden case with dry plate, and the result was as complete a photograph of the compass as is possible. It is perhaps no photograph in the ordinary sense, because no lenses are used. It is not a negative, but a positive plate that is obtained."

Another cable dispatch from London of the same date says:—"Scientists are greatly interested in the report of the experiments at Würzburg, repeated at Buda-Pesth, by which a positive picture is obtained by the agency of the Crookes tube through barriers of wood, cloth and flesh, and whole rows of books, bones, and metals alone remain opaque. But even of the latter aluminum is now discovered to form an exception. Prof. Thompson calls it a registration of shadows rather than a photograph, and it is curious that it can only be done without a lens. Photographers see no point in it for them, but its use in obtaining the minutiæ of a skeleton through any amount of flesh and muscle promises a revolution in surgery and medicine."

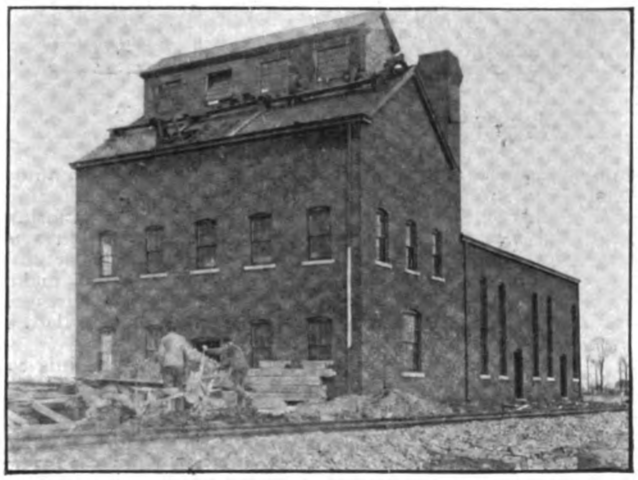
POWER TRANSMISSION.

THE CALCIUM CARBIDE PLANT AT NIAGARA.

BY ORRIN E. DUNLAP.

IT is expected that before this month ends calcic carbide will be made in the new plant at Niagara Falls. This is the first one of its kind in America and considering the great interest now centered on acetylene gas, which is made from calcic carbide, there is little wonder that close watch is being kept on the Niagara plant in anxious waiting for results to indicate the probable success of this new industry. The product of this initial plant will be sent to Philadelphia in barrels and there manufactured into acetylene gas to supply Southern Pennsylvania. The rights to manufacture calcic carbide under the Willson patent have been sold to capitalists in many sections, so that at present no fewer than 12 states are watching Niagara to learn more of the process of manufacture.

The new plant here being the first of its kind, it is but natural many interesting experiments will be made in it. At the start of operations it will be important to ascertain the amount of electric current which will prove the most economical, for so far the experiments have been made with current varying from 25 H. P. to 235 H. P. The contract of the company with the Niagara Falls Power



THE CALCIUM CARBIDE WORKS AT NIAGARA.

Company calls for 1,000 or more H. P., a force much larger than any used heretofore for the purpose.

The current is received all on one phase at 2,200 volts and used at a voltage of about 100. At the commencement it is likely that the furnaces will be operated with a current ranging from 100 to 1,000 H. P. and it is possible from the dimensions of the furnaces that a current of 500 H. P. will be found the most economical.

The present size of the Niagara carbide plant is 40 x 90 feet at the foundation. The structure, as shown in the accompanying engraving, is of brick, the front portion being two stories high, or 31 feet to the eaves. It contains a furnace room, a crushing and grinding room, a laboratory, a switchboard room, a transforming room and a room for the employees. The crushing and grinding portion of the outfit is to be of sufficient capacity to supply a plant of 50 tons capacity, whereas the capacity of the plant at the start will be at least 5 tons per day. A two-phase 75 H. P. motor will operate the grinding plant. In the furnace room four furnaces have been built, each containing cast iron crucibles 3 feet 6 inches long, 2 feet 8 inches deep, and 2 feet 2 inches wide. The current will be kept on each furnace for about three hours, one furnace being operated at a time. Each horse power used is supposed to give 20 lbs. of calcic carbide each 24 hours, and each pound of the product is supposed to produce a little over five cubic feet of gas. January will be a busy month at the plant, for on the 7th inst. the General Electric Company's force came on from Schenectady to install the electrical equipment, while the force from the parent plant in North Carolina and Mr. J. M. Morehead, of New York, the engineer in charge of the erection, are also here and will devote their united efforts to hurrying the plant to completion, so that by February 1, at the latest, the factory may be in operation.

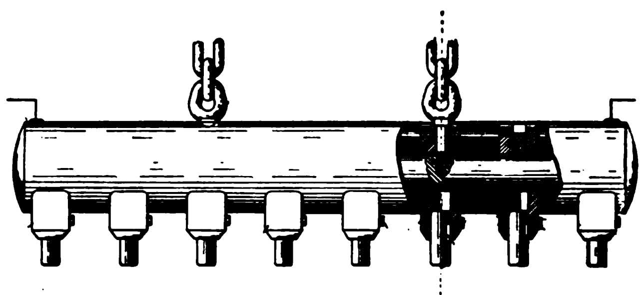
It is altogether likely that calcium carbide will be manufactured in the plant here at a cost not to exceed $5 per ton. In this connection the promoters of the plant give some interesting figures in stating that assuming that 20 pounds of carbide are produced each 24 hours for each horse power used, the amount made during 300 working days would be three tons per H. P. per year, and applying the 100,000 H. P. available from the present tunnel it would mean the production of 300,000 tons per year. This, they say, should produce at least 3,300,000,000 feet of acetylene gas, which, as its illuminating powers as compared with coal gas are as 10 to 1, would represent all of 33,000,000,000 cubic feet of this gas,—an amount that equals if not exceeds the annual output of coal gas throughout the whole United States. There is no doubt that other factories for the manufacture of calcic carbide to supply New York, Massachusetts, Ohio, Northern Pennsylvania, Indiana, Illinois, Rhode Island, Connecticut, Missouri, Michigan, Minnesota and other states are likely to be erected at the Falls because of its proximity to the fields from which the materials used in its manufacture are obtained, and also because of the great supply of cheap electrical power obtainable there.

DANIELS' MULTIPOLAR LIFTING MAGNET.

THE use of electromagnets for picking up and raising masses of iron in foundries and similar places has been proposed and tried to a limited extent; but the ordinary magnet with two poles is serviceable in this way only for small masses of iron of inconsiderable area. The use of a multipolar electromagnet, the poles of which are held in a rigid relation to each other and to the mass of iron to be lifted, is unsatisfactory except for application to masses or structures of iron of even surface.

To avoid this inconvenience Mr. W. P. Daniels has designed a form of multipolar "power" magnet shown in the accompanying engraving.

An important feature of the device consists in the con-



MULTIPOLAR LIFTING MAGNET.

struction of the pole-pieces in which there are provided the recesses. These recesses are adapted to receive pole extensions of wrought-iron, movable longitudinally in the recesses in the pole-pieces, their excursion being limited by set-screws, which project into the recesses and into the slots, provided within the pole extensions. The latter are prevented from falling out by the stops at the upper end of the grooves, while the extensions have an up-and-down movement limited by the length of the slots. The force of gravity will ordinarily be sufficient to withdraw the extensions and bring them to the lower limit of their excursion; but a spring may be added to insure the protrusion of the extension pole.

THE WATER POWER OF THE DRAINAGE AND SHIP CANAL, AND ITS TRANSMISSION TO CHICAGO.[1]

BY H. S. PUTNAM.

INCIDENT to the sanitary benefits of the Drainage Canal and especially to its use as a ship canal, a magnificent water power is made available which can be developed and utilized at a comparatively small expense. With the Drainage Canal, you are all more or less familiar, and its description here is not necessary. Its utilization as a ship canal has also been frequently agitated, and has been an important factor in its plans and construction. It may be some years before these plans are fully carried out, as the scheme is gigantic in its proportions and will require time and money to complete. However, upon the completion of the drainage canal a large portion of the expense of opening a deep water route from Lake Michigan to the Gulf will be covered. When we consider the vast importance of such a route to the whole Mississippi Valley, and ultimately, in connection with the proposed deep water ways to the eastward, to the whole country, in the matter of transportation facilities and freight rates, it is more than probable that the balance necessary to complete such a route to the Gulf will be forthcoming in the very near future.

The Drainage Canal when completed according to the present plans and contracts, will stop at Lockport and will have a flow of 300,000 cu. ft. of water per minute. After deducting say six feet for the slope on the surface of the canal, there will be available at Lockport about a twelve foot head of water. With a turbine of 85% efficiency, this will give us 5,800 available horse-power. Upon the completion of the canal, however, as a ship canal, with the flow at the full capacity—600,000 cu. ft. per min., a water power will be developed of immense value to that community, and also to this city. Lake Joliet just below the city of Joliet, is 76 ft. below the low water mark of Lake Michigan. Allowing six feet as before for the slope in the surface of the canal, we will be able to utilize the remaining head of 70 feet in two steps, one at Lockport, and the other at Joliet, of nearly equal amounts. As the tail races of the power used at Lockport can be turned back into the canal, no water will be lost, but it can all be utilized for the entire fall. Taking the efficiency of the turbine wheels as before at 85 per cent. and allowing a loss of one foot of the head in the rise of the water in the tail races and other obstructions to its flow, at each step, we have available 65,700 actual horse-power, in two steps of nearly equal amounts at Lockport and Joliet. The flumes for the utilization of this water power can be put into the canal when it is being built, at practically no additional expense, and the tail races can be built at a merely nominal figure as compared with the great amount of power to be developed. Thus in this case we avoid the common objection to water powers, namely, the immense cost of the necessary dams, etc., so as to make the water power available, compared with the amount of power used. The interest on the necessary money outlay, often exceeds the cost of coal where steam is used.

After the ship canal is built, provision being made for water power flumes, it is more than probable that all necessary tail and head races can be constructed for less than $50,000. Then again we have an available market for the whole of this immense power. It is probable that Joliet and Lockport can use only a small portion, but Chicago, with its population of two million, and a daily consumption of between two and three hundred thousand horse-power, offers a grand market. That this power can be transmitted to Chicago economically and profitably is what I propose briefly to show.

I will endeavor first to show the feasibility of the project from an engineering standpoint, and second, the financial phases of the question. We will first consider the power plant.

In building the retaining walls and locks for the ship canal at Lockport and also at Joliet, the flumes and openings in the wall for the water power can be left at practically no additional expense, and what little there may be, the authorities will certainly feel justified in creating in consideration of the financial returns that they can obtain from a rental of the power. Therefore we have only to consider our discharging tail race or shunt around the ship locks, as far as the handling of the water is concerned. Such a tail race would necessitate the removal of less than 25,000 cu. yds. of material, mostly rock. At Lockport this tail race would have to be constructed, but at Joliet it is very probable that the water could be discharged directly into the river at a very small expense. At the prices now prevailing in the country for this class of work, from 20 per cent. to 25 per cent. lower than the prices current at the time the contracts for the drainage canal were let, owing largely to improved machinery, this excavation for both plants would cost less than $25,000. Adding $25,000 more for the necessary retaining walls, would make this part of the plant cost approximately, $50,000.

The turbine wheels can be very easily made in pairs, each pair connected directly to the electrical generator, or whatever machinery it may be required to drive. With the head under consideration these pairs can be made of 3,000 horse-power each, 20 such wheels, say 10 in each station, being required for the entire plant. Ordinary turbine wheels can be bought for $1.00 per horse-power. Especially designed wheels, with necessary flumes, gates, regulators and erected in position, for about $5.00 a horse-power. To cover special features however, and also the two station houses, which would not be expensive, I have estimated the cost of the entire power plant with the turbines ready to run at $500,000, or $10.00 per horse-power. This figure can certainly be very considerably reduced.

Next, we must consider the method of utilizing this power, but more especially, in the present instance, its transmission to Chicago, a distance of 40 miles. To transmit this power by hydraulic pressure, even if practicable, is out of the question in the present case, as the only water available in sufficiently large quantities is from the canal, and there would be objections to returning the sewerage back to the city in this way. Compressed air is more feasible, but compressed air engines are not economical, and neither is the use of compressed air, unless it is reheated before being used, and also transmitted at a comparatively low pressure, which means large pipes. In point of convenience, ease in handling, adaptability and economy in transmission and use, electricity as a motive power, stands foremost at the present time. In the development of the immense water power at Niagara and its transmission to Buffalo, all these different methods were carefully considered and electricity finally adopted. By the use of electricity about 80 per cent. of the power developed by the turbines can be delivered to the consumers in Chicago; certainly a better showing than is made by the compressed air plants now in operation.

Adopting electricity, therefore, as the means of transmitting this power, the alternating current is selected on account of its flexibility, ease of conversion and the high voltage it enables us to use in its transmission, thus effecting an immense saving in copper. A low number of alternations per second, not exceeding 30, is selected so as to avoid the induction losses which would be excessive at a higher frequency. The use of this low frequency may interfere somewhat with the use of arc lights on the circuit directly, but by the use of proper rotary transformers this can be rectified. For all other purposes there is no objection to this frequency.

As it is not advisable to build generators of too high a voltage, the generators in question should have a voltage of about 2,000 volts, and in order to be directly connected to the turbines, of 3,000 horse-power, or 2,250 K. W. capacity each. It would be preferable to make these as large as possible and a careful consideration of the turbine wheels to be used might enable their size to be increased. The polyphase current would be adopted as offering numerous advantages over the single phase, especially in the use of motors, and the three phase instead of the two phase current on account of the great saving in copper in the transmission line, a very important consideration when the energy must be conveyed 40 miles. Step-up transformers changing the voltage from 2,000 to 20,000 volts should be used, as it would be impracticable to transmit this energy 40 miles at a low voltage on account of the immense amount of copper necessary. It requires 3,000 tons of copper at 20,000 volts. If we used 2,000 volts instead, one hundred times this amount would be required for the line, with the same percentage of loss. For the purpose of avoiding the inductive and condenser losses on the line, an overhead pole line is very much preferred, and this can be constructed very nicely along the banks of the canal. Owing to the inductive effects of large wires, comparative small wires are desirable, and consequently the circuits must be sub-divided. In this case No. 0 wire has been selected. It will require 30 circuits of three wires each of No. 0 wire to transmit the energy in question with a 10% loss. This will require 3,600 miles of No. 0 wire weighing over 6,000,000 pounds. As illustrating the importance of the size of the wire with inductive currents, if 0000 were used, it would require one-third more copper. The line has been computed on the basis of a 10% loss of energy, as probably the most economical in the present instance. Mutual induction between the circuits can be avoided by cris-crossing the wires on the pole line so as to counteract any mutual inductive effect between the adjacent circuits. Bare copper wire has been selected not only on account of its cheapness, but also because any ordinary insulation could not be relied upon at the voltage contemplated, so dependence will be placed upon the best grade of insulators for the insulation. A distance of 12 inches between the wires has been selected, as establishing a partial balance between the inductive and condenser effects. It is probable that with a very large load of motors on the circuit, as will be the case, the inductive losses on the line would be somewhat greater than has been taken. A considerable margin has been allowed for this in figuring the line, and the difference in phase caused by the highly inductive load can be rectified by the use of condensers. The use of synchronous motors, especially in the larger sizes, would also tend to prevent distortion of phase due to inductive losses.

For the purposes of this paper, the distribution and utilization of this energy for power purposes in large units is all that is contemplated. For local distribution, especially for lights and smal

1. A paper read at a meeting of the Illinois Chapter of the American Institute of Architects

powers, a local company would undoubtedly be organized to carry out that part of the business, or power could be furnished to the companies at present engaged in electrical generation. It is therefore probable that the power transmitted to the city would be utilized in units of considerable size, either by direct transformation to currents of lower voltage, suitable for general distribution for lighting and power circuits, or local transformation for power purposes at the plants of large consumers. These step-down transformers have been considered in the estimated cost of the plant hereafter made, but not the local distribution from these to the general consumer, as that is not essentially different from the methods already employed by the present companies, and presents no difficult engineering problems. Suffice it to say, that the alternating current can be distributed with greater economy and a more efficient and better balanced service than is possible with the direct current, when proper attention is paid to its details. Polyphase motors are also more efficient and require much less attention than direct current motors.

In the foregoing discussion, a 2 per cent. loss has been assumed in the step-up and also in the step-down transformers; a 10 per cent. loss in the line, and an efficiency of 95 per cent. in the electrical generators, and 85 per cent. in the turbine wheels. Apparatus is in use to-day showing fully as good results as have been assumed, and there is no reason why these figures cannot be equaled, if not improved upon, in the plant under consideration. These efficiences have of course been assumed under the conditions of full load, but the efficiencies of the apparatus as manufactured to-day would be only slightly less at any probable underload, while the losses on the line would be decreased. At full load, according to the above figures, the consumers would be furnished with 82 per cent. of the power received from the water wheels, and it is not probable that the efficiency of transmission would fall below 75 per cent. under any ordinary conditions of underload.

From the above it is readily seen that there are no serious difficulties in the way of transmitting this power to the city from an engineering standpoint. Financially the project is even more attractive. The following estimate has been prepared from actual figures which have been submitted to the writer by manufacturers, but in all cases increased in size to cover unexpected contingencies, and also the extra cost of getting only the very best of everything, irrespective of cheaper apparatus that might be obtainable, but possibly of inferior grade.

ESTIMATED COST OF PLANT.

Water-power plant, turbines and buildings complete	$ 500.000
Tail-races and discharges.......	50,000
Electric plant, including generators, transformers, etc...... ...	1,250,000
Transmission line, 3,600 miles No. 0 wire, pole line, etc..........	1,000,000
Distribution, sub-stations in Chicago............................	50,000
Engineering and sundries...............	150,000
Total cost...........................	$3,000,000

INCOME AND EXPENSES.

Rental of 50,000 H. P. at $25 per year....		$1,250,000
Interest on investment at 4 per cent....	$120,000	
Depreciation at 4 per cent..........................	120,000	
Repairs and supplies.	10,000	
Labor and superintendence.........................	40,000	$ 290,000
Excess of income over expenses...		$ 960,000
Deducting $5.00 per H. P. rental to Drainage District...........		250,000
Net income...		$ 710,000

Or 27 per cent. on the investment.

As will be at once seen from the above estimate, it is very liberal. In all probability the cost of the plant can be kept below two and a half millions. The charge of 4 per cent. depreciation on such a plant is excessive, as much of it is subject to but little, if any, depreciation. The interest charge is hardly an operating expense, but is put in on account of the prevalent custom to-day of bonding an enterprise to the full extent of the investment, thus making the interest a first lien on the income.

The charge of royalty or rental on the part of the Drainage District is an uncertain quantity, so it has been estimated at $5.00 per H. P. per year. This to the writer would seem to be an ample charge as compared with similar charges made at Niagara, but under very different circumstances.

The price charged consumers for the power, $25.00 a year per horse-power is, I think, perfectly practicable. According to the best estimates, it costs large consumers of power between $30.00 and $40.00 a year for power where it is produced by steam in large quantities. It costs small consumers very much more than this. A sliding scale of charges should, of course, be adopted according to the amount of power used. Consequently there should be little difficulty in disposing of the power at an average price much above that assumed in the estimate.

It was the original intention of the writer to take up some of the problems of the use and distribution of this electrical energy in the city, and the possible effects it might have, but this paper has already assumed sufficient proportions. Suffice it to say in conclusion, that we can scarcely over-estimate the importance of the Drainage and Ship Canal as a source of power to the City of Chicago, and that both from an engineering standpoint and financially it offers a very attractive field for our attention.

NIAGARA PLANT OF THE PITTSBURGH REDUCTION CO.

The works of the Pittsburgh Reduction Company have now been in operation at Niagara Falls for several months. The necessary electric current has hitherto been furnished through four of the General Electric Company's 400 K. W. rotary converters, but owing to a considerable increase in the reduction plant they have been found inadequate for the service, and each of these 400 K. W. converters is about to be replaced by one of 600 K. W. capacity. The new machines will be mounted upon the same base frames as the 400 K. W. converters and thus the converter plant will be increased one-half without any increase in floor space. A fifth converter of 600 K. W. capacity will be installed beside the others and will be similar to them in every respect. The total rotary converter capacity will then be 3,000 K. W. Including the transformers installed in the works of the Carborundum Company and the Calcium Carbide Company at Niagara Falls the General Electric Company will have furnished 5,000 K. W. capacity of transformers for operation in connection with the Cataract Construction Company's system.

NEWS AND NOTES.

CRUCIBLE CAST STEEL IN THE ELECTRIC FURNACE.

It has lately been proposed to prepare high-class crucible cast steel in an electric furnace (of a continuous type) provided with a basic lining similar to that already freely employed for ordinary furnaces used in the manufacture of lower grades of steel and of ingot iron. In the case of the preparation of a fine cutlery steel the purest procurable raw material would be used, certain samples of spathic iron ore fulfilling this requirement. The roasted ore would be reduced with wood charcoal in an electric furnace, and its contents of carbon, if too low, corrected by the addition of spiegeleisen. According to a recent article in the *Zeitschrift fuer Elektrochemie*, the computed cost of the finished steel in bar, even when spiegeleisen has been requisite, is about £12. 10s. per ton, a price by no means excessive. The whole operation can be conducted in a neutral or slightly reducing atmosphere, and it is practicable to maintain the temperature, at all stages of the process, at a point well above the melting point of the product, a considerable advantage.

A CITY ELECTRICIAN FOR BUFFALO.

Mayor Jewett of Buffalo advocates the appointment of a City Electrician, in these words, which are to be found in his annual message submitted to the Common Council on the 6th inst:—"Electricity is becoming so potent a factor in civilized life and figures so conspicuously in municipal problems that it seems to me that it would pay the city to employ an electrical expert, to be appointed by the Board of Public Works and known as the City Electrician. He should have charge of all electrical wires in the public streets and superintend the construction of all new electric lines, particularly those for the transmission of Niagara Falls power, and all new street railroad lines. It should be his duty to see that all proper precautions are taken to prevent the destruction by electrolysis of the water and gas mains now in the streets. The damage from this cause has been very large in some cities, and the authorities of Buffalo ought to be on guard to prevent a similar occurrence here. Plenty of work could be found for a City Electrician to do, and I believe the creation of such an office would be a wise and desirable step."

DISCREPANT "OUTAGES" AT CINCINNATI.

The police reports for December to the Board of Administration of Cincinnati, were filed a few days ago. The police reported 9,690 hours and 18 minutes' outages, and the Edison Company but 5,241 hours and 20 minutes' outages, a difference of 4.448 hours and 58 minutes. This involves a deduction of $97.88 from the Edison Company's bill. The Board decided hereafter to accept the police report as correct and final. There may be litigation on the matter, but the Board feels the position it has taken is demanded by regard for the public interests, and will maintain it.

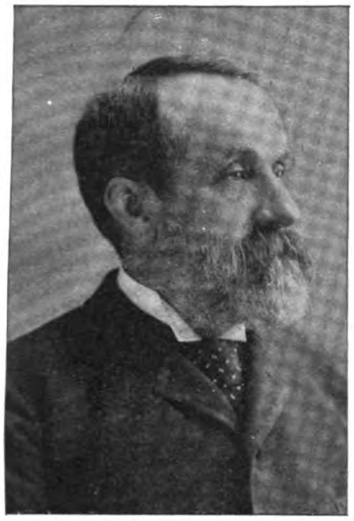
ONLY 1,782 MILES.

The steam railroad track laid in this country in 1895 did not exceed 1,782 miles, or the smallest quantity for any year during the past twenty.

MAGNETIC OBSERVATIONS ON HARDENED STEELS have led Mr. J. O. Arnold, in his paper on "The Influence of Carbon on Iron," read at the Institution of Civil Engineers, to the conclusion that (1) the magnetic permeability varied inversely as the carbon present; (2) the permanent magnetism was directly proportional to the carbides of iron present; and (3) in iron containing between 0.1 per cent. and 0.9 per cent. of carbon the permanent magnetism was directly proportional to the sub-carbide of iron present.

Telephony and Telegraphy.

THE NEW HOME OF THE PROVIDENCE, R. I., TELEPHONE COMPANY.[1]



Henry C. Cranston, President.

THE tremendous advance in telephone service which has characterized the history of the sound transmitter from its advent a comparatively short time ago to the present day, when it seems as if human invention can hardly bring it much nearer perfection, has in no city been more marked than in Providence.

Whatever improvement in telephonic service has been made has been at once applied here. The local office handles an immense amount of business, and with what success and ability the business men of Providence can best attest. From its modest beginning to its present position as a system with upwards of 5,000 subscribers, the advance has been steady, ever growing—ever improving.

The last step to be taken was that made when the old office in the Butler exchange was abandoned for the fine building which the central office of the company now occupies—a building built for and by the company, and with its every part specially adapted to some feature of the system's work.

The handsome new building of the Providence Telephone Company, in this city, a cut of which is herewith presented, was completed and occupied by them in April of 1895. Their old quarters in the Butler Exchange building becoming inadequate for the latest improved appliances, and the business demands, the construction of this building became necessary to comply with the outlay for increased facilities for the underground and switchboard systems.

The building is located on the easterly side of Union street, between Fulton and Washington streets, and is built in the Italian Renaissance style of architecture, of granite and Indiana Oolitic limestone for the first story and brick and white terra-cotta for the two upper stories.

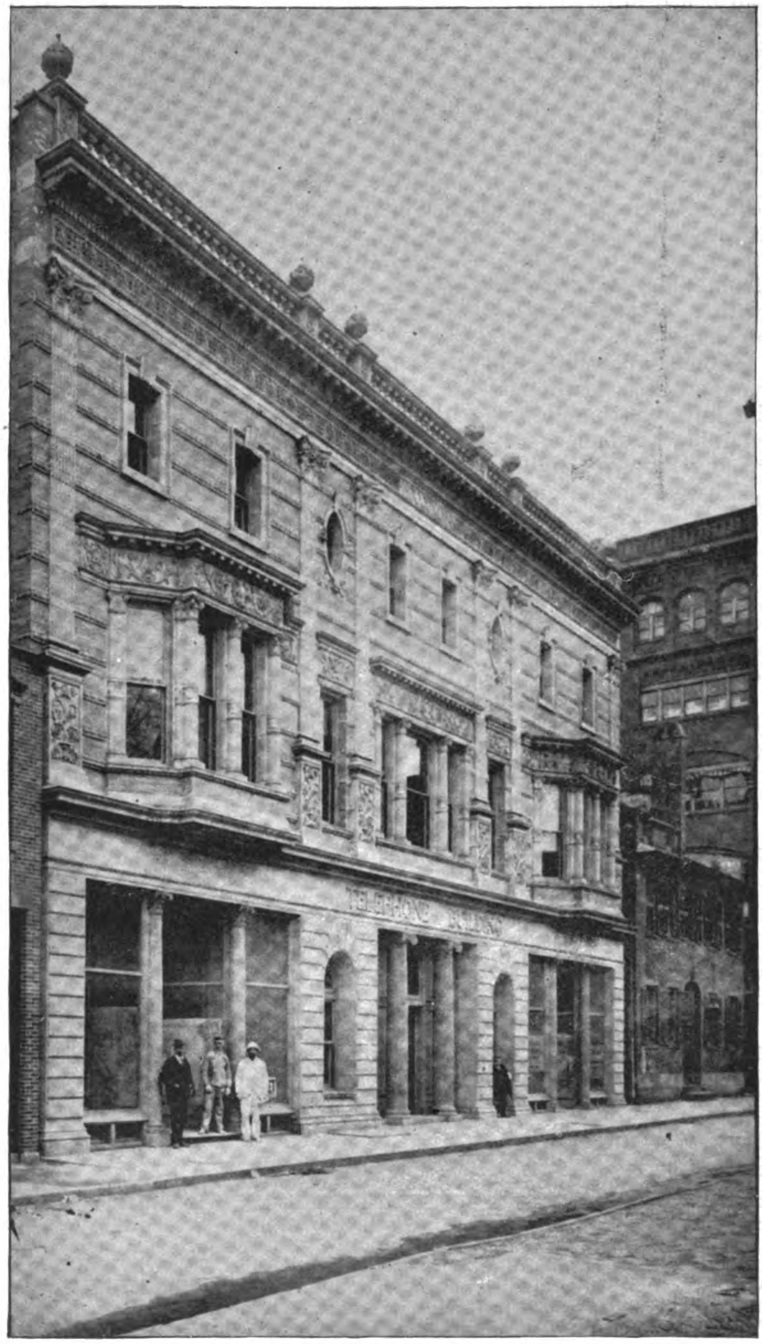
The location could hardly be improved on. Close by the building are the large dry goods houses. Just below it begin the banks and the larger business houses of varied interests. It is convenient for the business man from out of town who wishes to call up his home place, and equally convenient for its subscribers in town.

The building itself is a handsome one, and has a most unique appearance. The first story main entrance is flanked on either side by Ionic columns of polished granite, and leads into a spacious and well-lighted lobby, which has been furnished with sound proof booths, for long distance and local telephone service. The staircase to the second story leads to the business and directors' offices, the offices of the president, treasurer and general superintendent.

On the third floor is located the electrician's department, operating room, distributing room for all the wires terminating in the building, and the retiring room for the female operators.

The transfer from the old office to the new was accompanied by many sweeping changes and radical improvements in the system. The company keeping in line with similar systems in other cities, had gone into the work of laying the wires underground, an improvement the value of which can readily be estimated.

A new switchboard to care for 5,000 subscribers had to be installed, in this change, at an outlay of $60,000, and for the underground subways with the cable laid therein, a very much greater sum was expended. Some eight miles



Front View of Providence Telephone Building.

of trench were excavated, varying in depths from 4 to 15 feet, and 250,000 feet of pipe laid in these trenches. Each pipe is three inches in diameter, and is capable of receiving a cable of 220 wires.

By the use of the underground service to reach the sub-

1. *Providence Telegram.*

scribers, the multiplicity of overhead wires have been removed, and the possibility for line interruptions, such as has been experienced in the past, from high winds and ice storms, will be removed. The territory of the company embraces Rhode Island, and the towns of Attleboro and North Attleboro. There are 5,200 subscribers connected with their service and some 33,000, of which 22,000 are made at the Providence office, calls are answered and connections made daily in the system.

To the several suburban exchanges, metallic circuits are connected from Providence central, which give the subscriber perfect service to these several points. The long-distance service receives special attention, and the quarters set aside for it in the building are perhaps the finest furnished in any city of similar size in the country. The improved appliances, the comfort which one may enjoy, and the excellent service itself are all greatly appreciated by those busy men whose interests demand that they may have speedy communication with their business associates in distant cities.

At the Providence office there are sixty lady employees whose duty is to answer calls and make connections from the subscribers. All of the suburban exchanges are kept up-to-date in their equipment, and the use of lines through these out-of-town offices is made as convenient and as free from annoyance as the use of a line, the connection for which is made without going beyond the Providence exchange.

The company has had an existence of fifteen prosperous years. It is at the present time recognized as one of the leading quasi-public institutions of the city, and one which is doing as much in advancing the city's business interests as any other existant. The Providence Telephone Company was organized in 1880 with a capital of $35,000, which has been increased from time to time, as the demands for the service has required, until it is now $800,000. The men connected with the company include many of those best known in the city's life. Representative names are those which appear upon the company's printed matter as the men who control its work and guide its fortunes.

The board of directors and officers are as follows: Directors, Henry C. Cranston, Henry G. Russell, R. G. Hazard, R. M. Larned, James H. Chace, J. E. Hudson, H. F. Barrows, F. H. Peckham, Jr., S. U. Starkweather, Albert O. Morgan, Dexter B. Potter, Samuel P. Colt.

President, Henry C. Cranston; vice-president, Albert O. Morgan; treasurer, Charles T. Howard; general superintendent, Albert C. White.

THE RELATIONS OF POSTAL AND WESTERN UNION.

An official who speaks with authority on telegraph affairs says of the relations between Western Union and Postal telegraph companies from 1883 to 1887: "There were several comparatively small telegraph companies fighting one another and the Western Union, causing the greatest confusion in rates and disturbance of honorable business methods. Finally the Postal Telegraph Co. acquired some of these companies and the Western Union others. The folly of cutting rates, giving rebates and the like became apparent and an agreement was made to put an end to such practices. A good many rates were reduced in the process of doing so and the ruinously low rates were increased to reasonable figures. That arrangement has continued until now with decided advantage to both companies. The agreement has not expired, and I know of no reason why it should be terminated. On the contrary, there are many reasons why it should not. There is no war between the companies. Competition is very sharp, resulting in higher efficiency in the telegraph business than ever before. Neither company has the slightest interest in the other and both are naturally on their good behavior. There has never been any division of territory by the two companies and such a plan of business will never be adopted in my judgment."

St. Joseph, Mo.—It is stated that the new Citizens' Telephone exchange at St. Joseph is now in good working order with about 500 telephones in operation. The exchange was opened December 1, with 400 instruments connected, and Mr. G. A. Moss, the manager, says that he expects to have 800 going in a month or two.

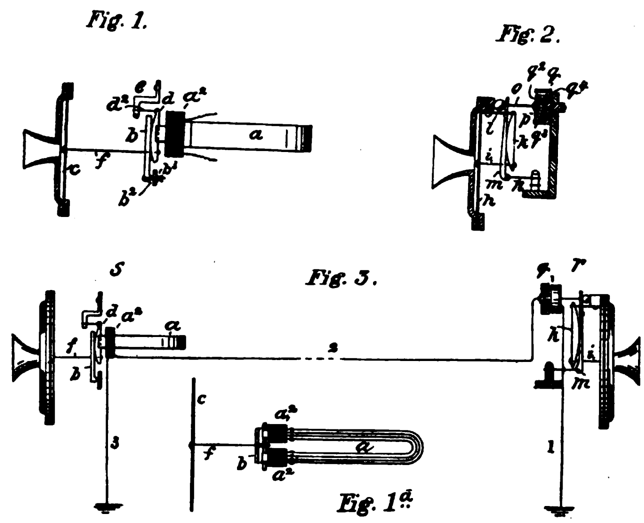
FIELD'S COMPENSATING TELEPHONE.

It is found in the practical transmission and reproduction of articulate sounds that the feeble and rapid fluctuations of current are affected by various electrical characteristics of the circuit in a different degree from the slower fundamental vibrations. They experience greater opposition from the impedance in the conductor and suffer more serious dissipation in the insulating medium of the circuit. Hence if the vibrations of the transmitted current were of amplitudes in strict proportion to those of the sound-waves impinging upon the transmitting-instrument, the reproduced sounds would be of quite different quality from the original sounds, the characteristic harmonics having been degraded or eliminated through various reactions of the circuit.

Mr. Stephen D. Field in a recent patent describes means to compensate for this unequal degradation of current pulsations of different periods and amplitudes by means of a mechanical device in the telephone which acts to accentuate or magnify the more rapid and feebler vibrations while diminishing the amplitude of the heavier vibrations. By thus transforming the mechanical vibrations of the transmitting diaphragm into distorted or disproportionate vibrations in the electric current, it is possible to compensate for the unequal effects of the circuit upon the different vibrations and to produce in the receiving-instrument mechanical vibrations in strict conformity with those of the transmitting-instrument.

In long insulated conductors or cables the static effect upon varying currents is particularly prominent. This so-called "retardation" is in fact an absorption of the energy of the current, and results in the extinction of the characteristic harmonic undulations. The invention therefore applies particularly to transmission through long cables or between distant stations.

The invention contemplates the interposition between the vibrating diaphragm and the transmitting device proper—the



Field's Compensating Telephone.

current-modifying portion of the transmitter—of a modified system of compensating-levers of the type known as "Houdin's compensating device." One of the levers is pivoted at one extremity and has its other extremity connected with the transmitting device. The other lever, which abuts upon the first-mentioned lever and has a curved surface rocking upon that lever, is also movably supported at one extremity, and has its other end fixed to the transmitting-diaphragm. The movements of the diaphragm are thus imparted to the transmitting device through the medium of these levers, whose point of contact, and hence whose ratio of movement, shifts in proportion to the amplitude of the sound vibrations.

The instrument is so adjusted that the vibrations of large amplitude cause the point of contact of the levers to shift in such a way that the movement imparted to the transmitting device is less than the excursion of the diaphragm, while when the diaphragm vibrates feebly the motion imparted through the levers to the transmitter are magnified.

The invention is applicable not only to transmitting but to receiving telephones. In its use in the latter instrument its function is obviously to magnify or exaggerate mechanically the degraded harmonic pulsations while diminishing the fundamental vibrations, thus in a manner restoring the transmitted impulses to their original condition.

Fig. 1 of the engravings is an elevation of the essential parts as applied in a receiving-telephone. Fig. 1a is a partial plan view of the instrument shown in Fig. 1. Fig. 2 is a sectional view of the same device in use with a transmitter of the granular carbon

type. Fig. 3 illustrates a transmitter such as shown in Fig. 2 connected in an electric circuit with a receiving-instrument like that shown in Fig. 1.

The receiving telephone in Fig. 1 comprises the permanent magnet *a*, carrying on its pole-pieces coils a^2, an armature *b* for the magnet, a diaphragm *c*, and a system of compensating-levers and mechanical connections between the diaphragm and the armature. The armature *b* itself is used as one of the compensating-levers. A lever *d* co-operating with this is the other. Armature *b* is lightly supported upon a knife-edge b^2, being held in place by link b^3. Between the pole-pieces of magnet *a* lies a lever *d*, which is supported at its upper extremity on a light spring d^2, fixed in a bracket *e*. The surface of the lever *d* which abuts upon the face of armature *b* is curved, so that as the armature rotates about its pivotal point b^2 the point of contact between the parts of contact *b* and *d* is shifted toward or away from the fulcrum b^2. The yielding spring d^2 permits to the lever *d* a sufficient longitudinal movement to avoid the sliding of its surface upon armature *b* and consequent friction. The free extremity of lever *d* is connected by a thin wire *f* with the centre of diaphragm *c*.

Referring to Fig. 2, it will be seen that the features shown there comprise essentially the same parts. The diaphragm *h* is connected through a wire *i* with one extremity of the curved lever *k*, whose other extremity is carried upon a yielding support *l*. The convex surface of lever *k* bears upon the flat surface of another lever *m*, supported on a spring *n*, the free extremity of the lever *m* being connected through a rod *o* with the movable carbon plate or electrode *p* of the transmitting device *q*. It has a small diaphragm q^2 carrying the electrode *p*, and constituting the cover of a cup-shaped receptacle containing granular carbon q^3 and having fixed to its wall another electrode q^4.

The operation of these instruments may be described in connection with Fig. 3, in which a transmitting-telephone is represented in a circuit 1 2 3, extending between two stations *r* and *s*. In this figure the levers are represented as being so adjusted that the point of contact between them is substantially intermediate of the point of connection with the diaphragm and that of connection with the transmitting device *q*. In this case the feeblest vibrations which disturb the diaphragm to the slightest extent, will not be perceptibly magnified. A slight vibration of the diaphragm to the right will obviously rotate the lever *k* about its support *l*, and this movement will be communicated to lever *m* and thence to the movable electrode in the transmitter *q*. A large excursion of the diaphragm, however, will produce a large movement of lever *k* to the right, whereby the point of contact between that lever and lever *m* will be shifted to a place nearer the fulcrum of lever *k* and farther from that of lever *m*, so that the movement of the electrode q^2 will be less than the excursion of the diaphragm. The vibrations imparted to this electrode will hence be of less amplitude than the original sound vibrations, and the amplitude of the undulation produced in the current by the change of resistance in transmitter *q* will be of correspondingly reduced proportion.

If desired, the instrument may be so adjusted that the normal point of contact between levers *k* and *m* is farther from the fulcrum of lever *k* and nearer that of lever *m*. Obviously, with such an adjustment the feeble vibrations, which disturb the diaphragm only slightly, would be magnified, the corresponding vibrations imparted to the transmitter-electrode from the extremity of lever *m* being of greater range than those of lever *p*. Thus the undulations of current in the circuit corresponding to fundamental acoustic vibrations would remain in direct proportion to the acoustic vibrations, while the amplitude of the harmonic vibrations would be magnified. At the receiving-station *s* also the instrument is adjusted to reproduce the minute vibrations in their normal proportions and the coarser vibrations in reduced proportions. A heavy pulsation through coil a^2 will so reduce the attraction of the permanent magnet upon its armature *b* that the latter will move outward, and hence will shift its point of contact with lever *d* nearer to the fulcrum of lever *b* and away from the fulcrum of lever *d*, reducing the movement imparted to the diaphragm through wire *f*.

If the conductor 2 were a cable characterized by high static capacity and absorption, the transmitting-instrument might be so adjusted as exactly to compensate for the degradation or modification experienced by the undulatory current in traversing the cable—that is, the transmitter would be adjusted to such a relation between levers *k* and *m* that the overtones would be just sufficiently magnified to compensate for their increased liability to absorption or obstruction, the fundamental tones being somewhat diminished in volume. This distorted transmitting-current would then result in a current at the distant station *s*, whose fluctuations would be exact counterparts of the original acoustic vibrations.

THE TELEPHONE IN THE BRITISH NAVY.

The British Admiralty appear to have grown tired of experiments with the voice pipe in warships, and are about to try experiments with the telephone. When the cruiser Fox had her steam trials the homacoustic voice pipe was fitted, and it was so arranged that there should be no leakage of sound; but the rattle of the machinery soon proved that this contrivance was faulty, and that the voice was inaudible at the other end. In the Rurik there are no fewer than fourteen telephone stations, and the Russian officers declare that the system works admirably. In the Majestic a moderate test is to be made, as only three distances are chosen—short and straight, long and tortuous, and intermediate.

COLVIN'S BATTERY TELEPHONE CIRCUIT.

IN a patent recently issued to Mr. F. R. Colvin, of New York, that inventor describes a novel arrangement of battery and transmitter in a telephone circuit, by means of which increased effect is obtained.

It is evident that with a circuit such as depicted in Fig. 1, where all instruments are in series, the receivers add together in inductance to cut down the effectiveness of telephone transmission, and what is of still greater practical effect the resistances of the transmitters add together to cut down the ampere value of the current, and thereby reduce the degree of fluctuation of the talking-currents. The strength of the battery-currents could in a measure be increased by placing the transmitters and receivers in parallel branches of the circuit, the battery still remaining in line, as shown in Fig. 2. In such arrangement, however, by reason of the high resistance of the transmitters, the main body of the current would follow the receiver branch and the strength of current in the transmitter branch would be low, thereby lowering the degree of current fluctuation under the voice-waves.

Mr. Colvin finds that the best results are attained when the

Fig. 1.

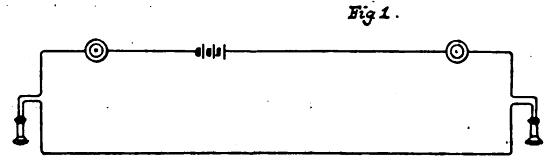


Fig. 2.

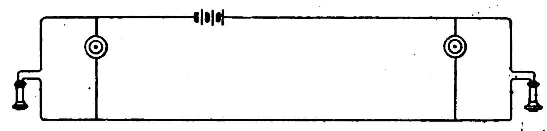

Fig. 3.

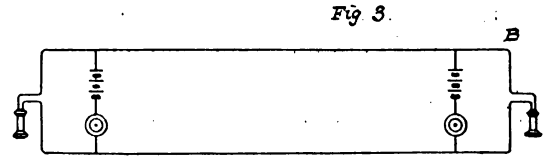

Fig. 4.

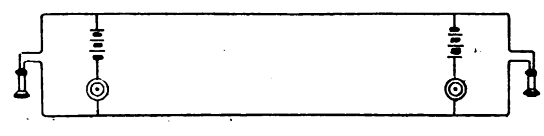

COLVIN'S BATTERY TELEPHONE CIRCUIT.

battery and the transmitter are both in the same branch and the receiver and transmitter branches are in parallel, as shown in Figs. 3 and 4. In such an arrangement it will be seen that the entire strength of the battery is exerted in the transmitter branch, the home and distant receiver receiving current in parallel, and therefore combining to lower the resistance of the circuit. The high resistance of the transmitter at the receiving end of the line diverts most of the current through the receiver branch. For example, suppose the transmitters have each a resistance of six hundred ohms and the receivers a resistance of seventy-five ohms. The strength of the incoming current in the receiving branch at the distant station would be about eight times as great as in the transmitter branch.

It will be noted that the transmitting-batteries in Fig. 3 have similar poles to line, whereas those in Fig. 4 have opposite poles to line. Mr. Colvin finds that the transmission is substantially of the same intensity in the two arrangements, a feature of considerable importance in practice where a number of circuits are to be interconnected through a central station, since it makes no practical difference how the two stations desiring communication have their circuits connected. Moreover, in installing or repairing a system no testing is required to determine the polarities of the wires, and therefore a saving of time and expense is effected.

It is evident that more than two stations may be used on the same line, the instruments always being placed in parallel with the battery interposed in the transmitter branch.

CONTENTS.

MUNICIPAL TELEPHONY.

THE agitation which is being carried on by some who believe that the government can operate successfully all enterprises of a commercial nature better than they can be handled by private individuals or companies has resulted in the establishment in the United States of a number of municipal electric light stations. The results which have been attained in the operation of these stations, viewed from the standpoint of the tax-payer, have been anything but encouraging, and we can recall but a few instances in which even a barely satisfactory showing is made,—and these only due to conditions which unfortunately do not obtain in the large majority of cases. It is not our purpose to enter here into a discussion of this question as applied to electric lighting, but we refer to it because recent events indicate that municipal telephony may be the next thing brought forward as the panacea for all telephone evils. Admitting that nothing stood in the way of such a proceeding, so far as patent rights are concerned, what are the arguments that are advanced by the advocates of the plan? They are identical with those of the electric lighting municipalites. In this instance, however, in order to find material for the substantiation of their claims, recourse is had to examples of European municipal or governmental telephony. The actual conditions of telephony in all the principal countries of Europe are admirably given in the book entitled "The Telephone Systems of the Continent of Europe" by Mr. A. R. Bennett, which was reviewed in the ENGINEER of July 17, 1895. This book has become the bible of the devotees of the new cult. But, as shown by our reviewer of Mr. Bennett's book, the conclusions drawn by the author were not warranted by the facts, and also arose largely from the failure to take into account the variant purchasing power of money in different countries. Mr. Bennett's aim has all along been directed towards securing municipal or governmental telephony in English cities, and it was largely due to his agitation of the subject that a Parliamentary Committee was appointed to inquire into the matter of telephone rates, which committee examined a large number of persons. The report has not yet been published, though several months have elapsed since the close of the hearings. But that Mr. Bennett's own countrymen are not all in accord with his views becomes evident in perusing the discussion of a paper entitled "Municipal Telephony," read by Mr. Bennett before the Northern Society of Electrical Engineers, at Glasgow, Scotland. This paper is based largely on the facts and views given in Mr. Bennett's work above referred to, and hence need not be gone into again minutely at this time; but the discussion brought out some points of interest which are particularly applicable to conditions existing in the United States. Thus, Mr. Henry Edmunds pointed out that in the case of Trondjeim, Sweden, a town of 30,000 inhabitants, selected by Mr. Bennett as a shining example of municipal telephony, there were no royalties to pay, no way leaves, no night service, no telegram service. With nearly 800 subscribers there were no multiple switchboards! Mr. Edmunds also pointed out that if each small town had its own system, with varying rates, varying conditions, and varying management, the confusion could be better imagined than described.

But there is one point which those who advocate municipal telephony are apt to lose sight of and that is, the necessity of giving the subscriber the power to communicate not only with parties in his own city but with those in other cities within a thousand-mile radius. That no city would or could undertake to place such a service at the disposal of its subscribers goes without saying, and yet it is equally certain that no telephone system could be complete to-day without it. The only alternative would be to put the large majority of subscribers to the necessity of paying for two services, one local and the other long distance. This, of course, is based on the assumption that the interurban or long distance lines are worked independently. To avoid such a condition of affairs there seems to be only one way out, and that is, for the government itself to take over the entire telephonic business of the country. This proposition viewed from the financial standpoint alone in these days when the government needs loans of $100,000,000 for running expenses is too ridiculous for serious discussion. Even the British Post Office, with the statutory power to acquire the telephone, under the general Telegraph Act, has not availed itself of its rights, but has, with a few exceptions, preferred to allow the existing companies to do the work on payment of one pound royalty per subscriber per annum. That the service as rendered at present in England by the companies must be fairly satisfactory is shown by the fact that the British Post Office telephone subscribers number all told only 1,300 for the whole United Kingdom!

We might adduce numerous additional facts to show the fallacy of the arguments of the advocates of municipal telephony but, leaving all other considerations aside, no one fully realizing what goes to constitute a good telephone service will, we think, place such a service at the mercy of municipal "politicians," at least until these have undergone a permanent change of heart.

PHOTOGRAPHY WITHOUT LIGHT.

THE announcement chronicled in our last issue that Prof. Rontgen had succeeded in photographing objects under the influence of electric radiation solely, has justly attracted worldwide attention, and this week we print additional confirmatory news of the photography of concealed objects by another experimenter, who has succeeded in obtaining pictures through an intervening medium consisting of aluminum plates an inch thick. While the discovery of this remarkable fact must command admiration, one can hardly suppress the thought that, now that it has been demonstrated, it seems so apparent it is strange it was not thought of before. The penetration of the Hertzian waves through various bodies has been the subject of a number of interesting studies which probably paved the way to the present discovery, but pending the receipt of more exact information the reported photography through a metal, aluminum, must be accepted with caution. At any rate the establishment of the fact that vacuum tube lighting makes it possible to photograph through opaque bodies opens up possibilities of the most far reaching consequence and cannot fail to have a direct application in most of the arts and sciences. Indeed it may become necessary to restrict the application of this discovery by legislative enactment. If what has reached us by cable be true, there can no longer exist any privacy in a man's own home, as any one armed with a vacuum tube outfit can obtain a full view photograph of any interior through a brick wall. Perhaps the house of the future will have a photograph-proof screen added to its walls and wide-awake inventors may get to work at once to devise such an one.

DEMAND FOR NIAGARA POWER.

IT is a pleasure to note how steadily the demand is growing for Niagara power, both on the spot and as far away as Buffalo. We illustrate and describe this week the calcium carbide factory just built at the Falls, and are glad to know that it soon have some more companions. Meantime, the industries already established are increasing their demands, and the Pittsburgh Reduction Co. making aluminum has just contracted the past week for 1,500 H. P. more from the big power house. The application of the power to the Niagara-Buffalo trolley road and to 12 miles of the Erie Canal with Mr. Lamb's scientific and successful system is far advanced, but this is not all, as apparatus is now being installed in Buffalo itself of such a nature as to be able to receive the Niagara current as soon as it can be delivered. Preparatory work on the pole line is being actively prosecuted, now that the contract has been closed with the city, and the present year will see a great deal accomplished in carrying out the plans of the courageous and farsighted backers of the great enterprise.

SUCCESS OF ELECTRIC CAR HEATING.

THE recent cold spells, so early in the season and so extreme in their severity, have done good work in proving the success and desirability of electric car heating. Where electricity has not been available, the managers of many roads have simply not tried to deal with the problem. The cable cars of the Metropolitan road in New York, for example, were run unheated and the passengers were often forced to leave them by reason of their unbearably low temperature. The New York Elevated road also, when the steam was needed for the locomotives, let its cars go cold, much to the disgust and suffering of the patrons of the road. But where the electric heaters were available, it was easy to maintain a comfortable degree of warmth, and fares instead of being repelled were attracted, in spite of an arctic climate keeping people indoors who were under no necessity to go out. Reports from all parts of the country tend one way, the newspapers commend the system highly, and the manufacturers are correspondingly busy. Any method of heating a steet car to-day other than electrical, is poor policy, and managers of roads are evidently coming to that conclusion very rapidly.

EDWARD WESTON.

THE announcement which we made last week as to the intention of Mr. Edward Weston to enter again the larger field of general electrical manufacture is one that has naturally been received with much surprise and interest. Of late years Mr. Weston has made an international reputation for himself as a designer of beautiful and accurate instruments, but it was not easy to see why he should so utterly abandon the scenes of his earlier successes. His work in electro-deposition and plating, his efficient and finely regulating dynamos, his methods of distribution, his incandescent lamps including those with the tamidine filament—all attested his master hand. We are glad to welcome Mr. Weston back to electrical engineering, and can assure him that there is plenty of work awaiting his skill and genius.

The reports that Mr. Weston intends also to devote himself actively to electrical journalism are the sheerest absurdity. Mr. Weston is a creator, not a critic or historian, and it is needless to say that he is perfectly willing to leave the drudgery of newspaper work to those who, while they record his progress with satisfaction, will not dream that they too are inventors.

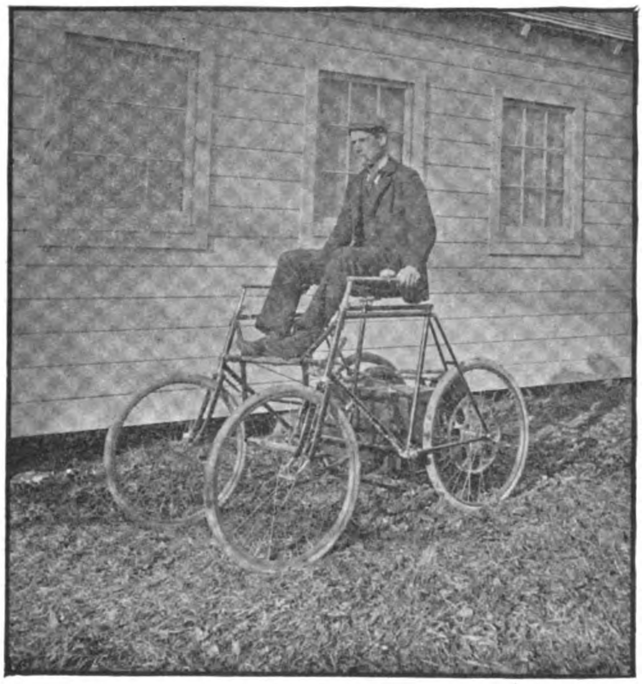
Electric Transportation.

THE RIKER ELECTRIC "MOTOR CYCLE."

OUR engraving represents the most recent attempt at adapting the electric motor to the propulsion of vehicles and the use of storage batteries for this purpose.

The motor cycle shown has been designed by Mr. A. L. Riker, president of the Riker Electric Motor Co., and is intended to be operated at a maximum speed of 12 miles an hour over ordinary roads, which speed it can maintain for 4 hours, thus giving at a travelling distance of 50 miles.

Two motors are employed, each of ½ H. P. and weighing



The Riker Electric Motor Cycle.

24 lbs. each. These are geared independently to the two rear wheels.

The storage batteries employed are of a specially light lead-zinc type and weigh 135 lbs. The total weight of the vehicle including everything is 310 lbs., which for its traveling radius is said to be the lightest motor-vehicle ever constructed. We understand that the Riker Company will shortly bring out electric cycles and carriages of all kinds.

LOW FARES IN BUFFALO.

Mayor Jewett has decided to approve the Buffalo Traction Company's franchise. The Company on its part formally agrees to grant certain concessions, the chief of which are these: 1. The reduction of the franchise from 66 to 50 years. 2. The sale of three tickets for ten cents. 3. Permission to the old company to use the tracks on the Elmwood avenue extension between Forest and Hertel avenues. 4. Free transfers. The franchise is to be signed and these provisions to be inserted hereafter by mutual agreement.

PRICE PAID BY THE NEW HAVEN FOR THE MERIDEN ELECTRIC SYSTEM.

It is ascertained positively from an official source that the New Haven Railroad Company, in acquiring control of the Meriden Electric Railroad system, paid $20 a share for 9,850 out of the 10,000 shares of stock, or $197,000, which represents the profits of the syndicate controlling the property, as nothing had been paid in on the stock. The New Haven Company also paid the floating debt of $70,000 and took at par $101,000 of the first mortgage 5 per cent. bonds of the Electric Company, which it holds in its treasury, including the bonds. The Meriden system thus cost the New Haven Company $368,000.

HOW THE LOWELL-LYNN 26-MILE TROLLEY WORKS.

The Lowell and Lynn line has been in operation a short time but the results already achieved justify the projectors in making the connection. Its especial value is that one can travel from Lynn to Lowell in about the same time that one can travel by the steam cars, and at just one-half of the fare. The cost from Lynn to Lowell is 40 cents each way, while the railroad fare is 80 cents each way. This means a great saving to a man with a family, who has business to transact in either city.

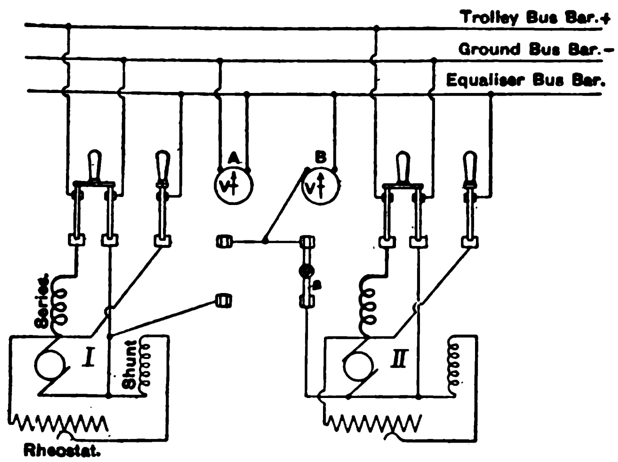
Recently one of Lynn's business men had occasion to make a trip to Lowell, and he was enabled to go there and back in the same time that it would take to go by steam railroad, and the cost was so much less that he was fairly delighted. Another incident of a similar nature is cited of a woman who left Lowell at 1.05 in the afternoon and arrived in Lynn at 3.45, transacted some business she had to do, spending an hour and returning on the car that leaves Lynn at 4.45.

The cars for Lowell leaves Lynn at 45 minutes past the hour, and it takes two hours and 45 minutes to make the trip. The cars run via the Lynnhurst line, so called, Wakefield, Reading, Wilmington, North Billerica, Billerica and Lowell.

HOW TO THROW ON A RAILWAY GENERATOR.

In the Dec. 27 issue of the London *Electrician*, Mr. H. Dubs, chief engineer of the Marseilles Tramways, describes a special switch combination for the purpose of preventing, as far as possible, a railway generator being thrown in circuit by careless operators before the equalizer switch has been closed.

The main double-pole switches and the equalizer switches are connected in the usual way. The voltmeter A is permanently connected with the negative bus bar and the equalizer bus bar, while the voltmeter, B, on which are taken the readings of the dynamos to be put in circuit, is connected with one pole to the equalizer bar, with the other pole to the upper terminals of as many voltmeter switches as there are dynamos in the station



Method of Throwing in Railway Generators.

All these voltmeter switches have only one common removable connection bar, *a*, fitted with an insulated handle.

This bar, or knife, is put into the voltmeter contacts of the dynamo to be put in circuit, but, as the voltmeter circuit B is then not yet closed, the operator, in order to take any readings on the instrument, has to close the equalizer switch II. By this simple device there is little chance of the operator forgetting to close the equalizer switch before putting the generator in circuit by means of the main switch.

As there is only one connection knife for all the voltmeter switches, the above device prevents, too, the short-circuiting of generators through these switches, which are generally very dangerous when of the double-pole type.

PROSPERITY OF THE NORTH CHICAGO LINES.

At a meeting of the directors of the North Chicago Street Railway Co. on Dec. 28, an extra dividend of 20 per cent. upon the $5,500,000 capital stock of the Company was declared. Ten per cent. of this, or $550,000, will be given as a stock bonus, and 10 per cent. in 6 per cent. debentures of the Company. The directors also voted an increase of $550,000 in the capital stock of the Company, for which stockholders will be allowed to subscribe pro rata at par. The stock sold that day on the Exchange at 308¼, and figured on a basis of 300 the stockholders get $3,000,000 in bonuses and rights.

THE TROLLEY AND THE ELEVATED IN BROOKLYN.

THE report of the Brooklyn Elevated Railroad for the year ending December 31, 1895, confirms the general surmise that the strike on the Brooklyn surface railroads was a most fortunate occurrence for the steam line. A deficit of $141,340 in operating results for 1894 became at the close of 1895 a surplus of $64,989; and the table of monthly returns shows how this surplus was made possible. The number of passengers carried, which in 1894 averaged 2,796,705 per month, rose in January, 1895, the strike month, to 4,271,994, held at 3,936,332 during February, and then gradually receded to the lowest figures for the year, 2,770,005 in August. The monthly average of passengers carried in 1895 was 3,338,963. Net earnings also showed a marked increase. Averaging in 1894 about $56,000 per month, they rose in January, 1895, to $109,010, though the monthly average for the year was only about $76,000. The months of April and May, 1894, showed the only monthly surplus earnings of the year. From a deficit of $11,424 for the closing month of 1894, the returns show a sudden transition, indicating a surplus in January, 1895, of $39,205. Until July the surplus continues, although fast decreasing, and for the rest of the year, excepting October, a deficit is returned.

The number of passengers carried is given as follows: 1895, 40,067,555; 1894, 33,560,462; 1893, 35,882,508.

A computation based on these figures shows that the cost to the road for carrying each passenger in 1895 was $.0503; in 1894, $.0558; in 1893, $.0518, actual cost of transportation, excluding fixed charges, ranging in the meantime between two and one-half and three cents per passenger. Similar computations from returns of the Manhattan Elevated Railroad show that for the year ending September 30, 1895, the total cost, including interest and dividend charges for transporting each passenger was $.0538, an increase of $.0034 over the cost during 1894. The figures are instructive as to the cost of operation under steam power, and significant when compared with similar figures for trolley operation. Their bearing on the arguments of those who oppose the building of a rapid-transit road to be operated electrically are important.

President Ullman in his report bears testimony to this, and reveals the fact that his Company was back of the conspiracy to limit trolley car speeds. He says in part: "The year opened with gloomy prospects. . . . The main streets of Brooklyn were perverted from their ordinary uses into overland routes for the operation of 'lightning express' trolley cars. . . . Killing and maiming was the rule and not the exception of the day. Emigration from instead of immigration to Brooklyn was evidenced during all the year 1894. To meet the situation, the directors resolved to co-operate with the authorities for a readjustment of transit conditions, relegating to the elevated railroads rapid transit, for the benefit of long-distance riders, and to surface electric railroads slower transit, consistent with safety on the surface of the streets for local riders." This solicitude for the safety of the public bore fruit, as is evident from the report, which adds: "In the spring of 1895 the authorities recognized the necessity of regulating the speed of surface railroads in order to stop the wholesale slaughter of Brooklyn's citizens, and on May 1, 1895, a city ordinance limiting the speed of trolley cars to eight miles maximum per hour in the old twenty-eight wards of the city went into effect. It was observed by the trolley companies to about July 15, 1895, and during that time its results were manifest. The number of accidents decreased, and with it travel in Brooklyn increased, as was demonstrated by the larger earnings of the elevated railroads."

The report also denounces the four-cent fare proposition of the trolley roads, calling it a dodge to divert attention from violations of the speed ordinance.

ADVOCATING THE NEWARK, N. J., TROLLEY FREIGHT.

Elias S. Ward, president of the Newark and South Orange Electric Railroad Company has sent the following open letter to the Board of Works in relation to a trolley freight system :—

Gentlemen: As a citizen of Newark who may have its interests at heart, although president of a street railway company, I call upon you to exercise very careful judgment in the consideration of the ordinance relating to freight service on the trolley lines. At the present time several large companies, representing millions of dollars, are looking for locations for factories where the best railroad facilities can be acquired. To drive the capital away from Newark means that its working people are deprived of their chance for wages, and its stores of their opportunity for profit. Millions of dollars have been invested in the street railroads of Newark, which have been the principal cause of its increased population and prosperity. Newark has at the present time as good a street railway service as any city of its size in the world, and your Board and its citizens should give the railroad companies the credit they deserve. Our geographical position places us in the most advantageous situation for manufacturing of any city on the Atlantic Coast. Why should we not take advantage of such a condition? I myself know of a million-dollar enterprise which will be driven away by the ordinance if passed in its present state, and see no reason why your Board should not consult with those who are interested in great enterprises in order that the best results may be obtained. Pounding investors is not the way to increase the growth of a city. Look back five years, and see what we had then; co-operate with the enterprise of Newark and see what can be accomplished in the next five years. Prosperity can come only with broad ideas, and the general welfare will advance in proportion to the activity and courage of our own people.

ELECTRIC TRACTION ON THE BROOKLYN BRIDGE.

The question of substituting electricity on the Brooklyn Bridge cars in the place of the locomotives, which are at present used in switching the trains in both terminals, will soon come up for final settlement. The General Electric Company has been engaged in fitting up one of the regular bridge cars with motors and this will take the current through a trolley pole from an overhead wire, which is to be strung in the terminals. One of these cars is expected to be able to draw three other cars to and fro on the structure and switch the train at both ends of the bridge. The work of fitting up the experimental car will be completed shortly, and when the specially constructed trucks arrive from Chicago and are attached to the car, the experiment will be tried. If the motors work successfully, it is the intention of the bridge management to equip a number of cars in a similar fashion, and, after doing away entirely with the locomotives, to use them in switching trains from the incoming to the outgoing tracks.

MUNICIPAL STREET CARS FOR PHILADELPHIA.

Resolutions were adopted on Dec. 26 by the Citizens' Committee of Twenty-one urging the Select and Common Councils to take such action as will most speedily result in vesting ownership of street railways in the city so that the city may lease them to the highest and best bidders under proper conditions and restrictions.

MORE STREET RAILWAYS FOR NEW YORK CITY.

The Empire City Traction Company has been incorporated to build and operate a street surface railway three and a quarter miles in length in New York City. The termini of the road are Hudson River and West One Hundred and Forty-fifth street; Harlem River and West One Hundred and Forty-fifth street; Hudson River and West Ninety-sixth street; East River and East Ninety-ninth street. The capital stock is $100,000, and the directors are: H. L. Scheuerman, F. H. Knight, E. M. Johnson, B. F. Defrece, F. W. Elder, M. J. Katz, H. W. Mayer, and Homer Scoville of New York, and Samuel Slater of Arlington, N. J.

REPORTS OF COMPANIES.

N. Y. EDISON ELEC. ILL. CO.

The Edison Electric Illuminating Company of New York has declared a quarterly dividend of 1½ per cent., payable Feb. 1. Coupons of the first consolidated mortgage bonds of this company due Jan. 1 will be paid at the office of the State Trust Company.

CONSOLIDATION OF LIGHTING INTERESTS AT HARTFORD, CONN.

NEGOTIATIONS have been pending for several weeks between the Hartford Electric Light Company, capital $350,000, and the Hartford Light and Power Company, capital $150,000, the two electric light companies for consolidation. It is reported that the arrangements have been completed by which the former company absorbs the latter.

A BALTIMORE EDISON CONSOLIDATION.

The Maryland Electric Co., and the International Telegraph District & Construction Co. have consolidated, forming the Edison Electric Illuminating Co., with a capital stock of $1,770,000. Alfred A. Glasier, is president; E. S. Webster, vice-president, and J. Frank Morrison, manager. The Maryland Electric Co.'s present plant of 1500 arc lights and 15,000 incandescent ights will be enlarged, and another plant of the same capacity will be built.

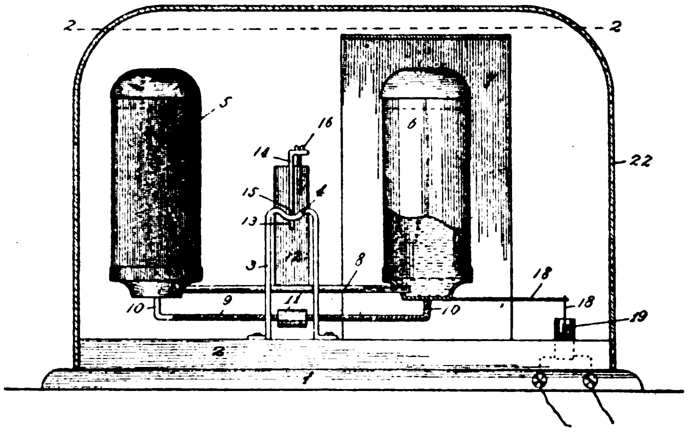
TOPEKA TELEPHONE TROUBLES.

C. O. Knowles has been appointed receiver for the Topeka Telephone & Electrical Co. by the district court. This is the outgrowth of a suit brought by the Harrison International Telephone and Cole's Construction Company of Chicago to collect $9,000 for telephones delivered to the local company. This suit is still pending, but E. A. Roseir, of St. Louis, who holds $15,000 of the company's bonds, became alarmed and asked for the receiver. The local management will not be changed, and the company makes the claim that the telephones sent from Chicago were rejected as unsatisfactory.

MISCELLANEOUS.

AN ELECTRIC SUNSHINE ANNUNCIATOR.

MOST meteorological observatories nowadays are equipped with sunshine recorders, and their indications are filed in the same manner as those of rain, temperature, etc. A form of automatic recorder for this purpose has been recently devised by Messrs. Hunt and Duenckel, of St. Louis, Mo., which we illustrate in the accompanying engraving. It consists of a pair of balanced bulbs filled with liquid, connected by a tube and suspended on a knife edge. One of the bulbs has a bright surface and is screened from the rays of the sun by a cover; while the other is blackened so as to absorb the heat rays of the sun. By adopting this construction it is evident that the heating of the blackened bulb causes the



ELECTRIC SUNSHINE ANNUNCIATOR.

expansion of the air in it and drives the liquid over into the screened bulb. This disturbs the equilibrium of the pair, which tips over and causes the arm carrying contact points to dip into mercury cups and to actuate an electric register. The cooling of the bright bulb allows the liquid to flow back and opens the electric circuit by bringing the arm out of contact with the mercury cups.

CONTEMPORARY ELECTRICAL SCIENCE.

THE old problem of contact electricity has found another investigator in C. Christiansen, who gives a first instalment of his results in the current number of *Wiedemann's Annalen*. The method used was that of drop electrodes of mercury, the differences of potential being measured between the reservoir and metallic plates dipping into the mercury caught. It appears to have been very difficult to obtain consistent results, but the general tendency of the experiments went to show that the oxygen of the air plays a very considerable part in the electric phenomena. Thus, drop electrodes of zinc amalgam and of pure mercury gave rise to different potentials in air, but the difference vanished when the drops passed through hydrogen.—Ludwig Silberstein evolved a law governing the dielectric constants of mixtures out of his inner consciousness, and then set himself to prove it experimentally. Given two perfect dielectrics which mix perfectly without contraction of volume, and given their specific inductive capacities, what will be the result of mixing them? The law in question is that the new specific inductive capacities will be the sum of the products of the volumes into the specific inductive capacities, divided by the total volume. Silverstein succeeded in finding only two such substances for his test experiment: benzol and phenylethylacetate. The maximum deviation from the formula was 4 per cent., and the average 1.7 per cent. So this process of mathematical law-making may be considered a success.—G. Meyer contributes a laborious investigation into the differences of potential between metals and liquids in connection with the theory of the capillary electrometer, which, by the way, appears to be increasing its sphere of usefulness. Helmholtz's charge-current theory of this instrument is undermined, and the author's conduction-current theory is strengthened by the results obtained.—Another highly interesting portion of Paalzow and Neesen's Paper on "The Passage of Electricity Through Gases" appears in the same number. Many curious facts were observed. On surrounding the discharge tube by different media, such as water, alcohol, or turpentine, the discharge is extinguished. This effect is not due to conduction, since the current is, if anything, enfeebled. On placing a point electrified by a Holtz machine near the tube, discharge was facilitated, and on moving the point all round the tube discharge took place even at atmospheric pressures.—K. Mack has continued his researches on the double refraction of electric rays. In the present paper he repeats the experiments with rays of various wave-lengths, proves that the two rays are propagated with different velocities in wood, and describes the preparation of artificial anisotropic media, in the shape of modified Hertz gratings, or—more simply—piles of newspapers!—*London Electrician*.

ORIGIN, OBJECT AND EFFECT OF SEC. 4887.

BY W. C. DODGE.

NOW that the Supreme Court, after years of effort, and the expenditure of many thousands of dollars, has finally construed Sec. 4887 of the Patent law, and as all are agreed that the law should be amended, it may be well to consider briefly the origin and object of the provision which limits the protection to an American citizen to the term of his shortest prior foreign patent.

As now construed, that section becomes a statute to punish the American inventor, if he refuses to give his invention free to all the rest of the world while compelling our own citizens to pay for its use: because, if he patents his invention in the United States alone, he can have a full term patent, for seventeen years; but if he tries to derive something from his invention abroad, to make foreign citizens pay for its use there the same as our own citizens do here, by patenting it abroad, then he is punished by being allowed at home only a portion of the full term, it being limited here by the life of his foreign patent which has the shortest term to run. If he does not patent it abroad, our competitors have it free from the start.

It will not do to say that he can prevent this by taking his patent here first, for two reasons; first, because in most foreign countries a valid patent cannot be had after a patent has issued here, or the invention has been made public there; and as our patent office sends the *Gazette* and copies of all our patents to nearly all foreign countries in exchange for their publications, the invention becomes public abroad almost immediately on the issue of the patent here. Second, because of the different manner in which the grant of patents is conducted at home and abroad.

Most foreign countries have no such system of examination as we have, and they grant the patent as a matter of course, on payment of the fee and certain proceedings had, say, in from six to nine months; whereas, in the United States no one can form any idea as to when the patent will issue, if at all, whether in three months or three years after the filing of the application. If our system were the same as theirs, and we could know that the patent would issue here in a certain definite time, then a party could so time his foreign applications as to have the patent issue here before, or at the same time as his foreign patents; but as matters are now conducted, that is impossible, for no one can tell how long his case may be held in the office here.

Again, a party here is liable to have his application put into interference with another, and that will delay the issue of the patent from one to three years, and in some cases they have been delayed by interferences ten to fourteen years.

True, patent attorneys try to avoid this difficulty by having foreign applications filed on the day the patent issues here, but as yet no one knows whether patents so issued abroad will be held valid or not, for so far as I have been able to learn, that question has not been passed upon by their courts. Moreover, a patent is liable to be stopped and put into interference in our patent office, even after it has been printed and published in the *Official Gazette*, and when it is too late to prevent the filing abroad; and thus while the patentee has taken every means in his power to prevent it, his foreign patent will issue first. In a case of my own, the Commissioner even went so far as to take my patent out of the post office after it had been signed, sealed and mailed to me, cancelled it on the official records of the patent office and put it into interference with an application filed the same day, a practice since declared unauthorized and illegal, by the Supreme Court.

Now this punishment of the American inventor is contrary to the spirit and intent of our patent system. It certainly could not have been the intention of Congress originally to thus punish him, and I think it perfectly clear that no one had any such idea at the time the limiting clause was first introduced into our patent law. A brief review of the several acts I think will make it clear that that limitation was designed to apply to foreigners who had already patented their inventions in their own countries, and not to American inventors at all.

Our first patent Act of 1790 authorized the grant of a patent to "any person," citizens and aliens alike. That was a very crude law, and existed less than three years. The Act of 1793, authorized the grant of a patent *to citizens of the United States only*.

Evidently Congress concluded that this Act of 1793 was not in accord with the object of the patent law as set forth in the Constitution, which was: "To promote the progress of Science and the useful Arts," for, of course, progress would be promoted by the introduction of inventions made abroad as well as by those made at home. Besides, it was impolitic to exclude foreign inventors, for at that time we had practically no manufactures, and it was therefore a matter of national importance to induce foreigners to bring hither their inventions that the nation might

have the benefit of them. Accordingly from that time on we find Congress letting down the bars to alien inventors step by step.

Section 1, of the Act of 1802, extended the right of a patent to aliens who at the time of filing their applications, had resided two years in the United States. The Act of 1832 provided that if the invention patented to an *alien* in the United States was not introduced into public use within one year from the issue of the patent, or was not in public use for a period of six months at any time after its introduction, or in case the alien patentee failed to perfect his citizenship within the earliest period within which he was entitled to perfect it, in each of such cases the patent should "cease, determine and become absolutely void without resort to any legal process to annul or cancel the same."

Section 8 of the Act of 1836, provided that "nothing in this Act contained shall be construed to deprive an original and true inventor of the right to a patent for his invention, by reason of his having previously taken out letters patent therefor in a foreign country, and the same being published at any time *within six months* next preceding the filing of his specification and drawings" in the United States.

Section 9 of this Act authorized the grant of a patent to "any person," citizen or alien, but made a distinction in the fee for the same. A citizen, or an alien who had resided in the United States two years and had made oath of his intention to become a citizen of the United States, was required to pay $30. Subjects of Great Britain were required to pay $500, and subjects of all other countries $300.

Section 15 of this Act also provided that the failure of an *alien* patentee for eighteen months to put his invention into public use in the United States and continue it on sale to the public, on reasonable terms, should be a bar to his recovery in a suit for infringement.

It will be observed that during all these years, no such condition as to working the invention, keeping it on sale on reasonable terms on pain of forfeiture, etc., was applied to the citizen inventor, but only to aliens. It was as though Congress had said to foreign inventors: We need your inventions, and we will grant to you the privilege of patenting your inventions in the United States on certain conditions different from those applied to our own citizens, but if you fail to put them into public use within a specified time your patent shall become void, or in case you sue on it you shall not recover anything for its infringement.

All this shows clearly that the object of Congress in thus modifying the law in behalf of alien inventors, was to induce them to bring hither and introduce into public use their inventions, and thereby help "promote the progress of science and useful arts"—in other words, the growth and prosperity of the country. In it all, there was no limitation of the rights of the citizen inventor, in any respect whatever.

In 1839 Congress went still further to induce alien inventors to bring here their inventions, for in Section 6 it provided that "no person shall be debarred from receiving a patent for any invention or discovery by reason of the same having been patented in a foreign country *more than six months* prior to his application in the United States, provided that the same shall not have been introduced into public and common use in the United States prior to such application; and provided also, that in all cases *every such patent shall be limited to the term of fourteen years from the date or publication of such foreign patent.*"

Here for the first time we find introduced the idea of a limitation of the term by the existence of a prior foreign patent. But in reference to whom was this limitation made? While the language used was such as to render the limitation capable of being applied to all patentees alike, both alien and citizen, a brief consideration of the circumstances existing at the time makes it clear to me that Congress had in view only foreign inventors.

It was for the foreign inventors that Congress was modifying the conditions. It said to them: No matter if your invention has been patented in your own country for more than six months, or any number of years less than a full term, we will still allow you to patent it here, but with the understanding that it shall expire here at the end of fourteen years from the date of your foreign patent, which was then the term of the American patent, and also that of the British patent, from which latter country nearly all our foreign applications came or were expected to come at that time. In fact, but very few countries had a term of more than fifteen years, or have at present.

Now at that time, few if any Americans took out patents abroad, while many more foreigners took patents here. I know of but two Americans who took patents abroad prior to 1839 (though there may have been more) while the record shows that sixty-eight foreigners took patents in the United States up to 1840, all but thirteen of whom were from England. It is a singular fact that these two Americans, Colt and Morse, both took out their foreign patents first. In Colt's case, it was simply because he happened to be abroad when he made his invention, it being patented in Great Britain in 1835, and in the United States in 1836.

Morse's case was different. He filed his application in the United States April 7, 1838, had it allowed and then placed in the secret archives as provided by law, while he went to France to patent it there, as otherwise he could not obtain a valid patent there. His French patent was dated August 20, 1838, while his United States patent was not issued until June 20, 1840; and it was this prior issue of his French patent on which his opponents relied to defeat his United States patent, in the case of O'Riley vs. Morse, 15th *Howard* 112. In that case the Supreme Court held that his patent was valid notwithstanding the issue of his French patent almost two years earlier; but the Court did not pass on the question as to whether the fact of his invention having been patented abroad first, would or would not limit the term of his United States patent.

It did say, however, in emphatic terms, that inasmuch as he had filed his application in the United States first, had paid the fee and complied with all the requirements of the statute, his United States patent was valid notwithstanding the prior issue of his French patent.

The same reasoning, it would seem, ought to apply to the other question, as to whether or not his United States patent would expire at the same time as his prior French patent; and to have determined that in such a case where the applicant had first filed his application in the United States the prior issue of a foreign patent should have no effect on the term of his home patent, any more than on its validity. But unfortunately, the Supreme Court in that case, as subsequently in the case of Bate Refrigerating Co. *vs.* Hammond & Co., decided in 1889 (9 S. C. *Reporter* 225), refused to pass on that point, though in this latter case that question was fully presented and argued by counsel employed for that special purpose, in order that those interested might know what the law was, and act accordingly. This was the more unfortunate because of the conflicting decisions of the lower courts on the meaning and effect of this Section 4887.

Of course this refusal of the Court was based upon its time-honored rule never to decide any question not absolutely necessary to dispose of the case at bar, a rule which it would seem greatly for the public interest to abolish or modify.

It is safe to say that in no other patent case has there ever been so many conflicting decisions involving such large interests as in those construing Section 4887; and nothing could better demonstrate the necessity for the establishment of a special court to try patent causes, by which some uniformity of decisions might be secured, and the rights in property which at most exists but for seventeen years, be speedily determined.

For an illustration of the conflicting decisions on this section the reader is referred to THE ELECTRICAL ENGINEER of April 2, 1890, p. 146, where three different decisions are printed in parallel columns, all written by the late Justice Blatchford, two while on the circuit, and the other while on the Supreme bench. As was well said, a comparison of those decisions is calculated to throw a shade of doubt upon the assertion of Blackstone that "the law is the perfection of human wisdom." Two of them held one way, and the other held exactly the opposite!

The reason for thus limiting the term of patents issued to foreigners who had previously patented the same invention abroad, is obvious. It was simply to prevent the American manufacturers and public from having to pay royalties for the use of those patents in the United States after the inventions had become free to their foreign competitors and the public abroad, by the expiration of the foreign patents for the same. That was the sole reason. It was wise legislation for the benefit of our own country, —first to induce aliens to introduce their inventions here, and second to so arrange that our people should not be at a disadvantage with those of other countries.

It must be remembered that at that time ours were truly "infant industries," our entire manufactured products as late as 1880 amounting to but $80,000,000, as against nine billions and over in 1890. We were struggling to build them up, and the Congresses of that day with true statesmenship, legislated in every way possible to that end.

At that time it never entered the mind of any one, that this limitation of the term applied to any except alien inventors, and to them only when they had first patented their invention abroad. As before stated, very few Americans took out foreign patents; and as was the universal custom everywhere, it was presumed, of course, that if they did, they would secure the patent at home first, just as the alien inventors did in their countries, or, at least, would file their applications at home first as Morse did.

Section 8 of the Act of 1842 still further opened the door to aliens by permitting them to take patents on designs in the United States, the same conditions applying to these as to patents for mechanical inventions. The Act of 1861 re-enacted the law in regard to alien inventors, and without any change in the fees.

In the revision of the United States Statutes in 1869, the language of the section was changed to read as follows:

"No person shall be debarred from receiving a patent for his invention or discovery by reason of his having first patented it in a foreign country; provided the same shall not have been introduced into public and common use in the United States prior to the application, and that the patent shall be limited to seventeen years from the date of the application of the foreign patent." This change to seventeen years was to make it correspond with the term of the United States patent as fixed by the Act of 1861.

The marginal note to this section of the revision reads as

follows: "Foreign patents may be patented;" and again, in the marginal note to Section 4887 in the copies of the law published by the Patent Office in 1885, and subsequently, was this:—"Patents for inventions previously patented abroad," may be patented, etc.

From the fact that all this had reference to "prior foreign patents," in connection with the general understanding that a prior foreign patent meant a patent granted to a foreigner in a foreign country first, the inference seems clear, that the limitation was designed to apply to such patents only, and not to those of our own citizens – certainly not to those citizens who filed their applications at home first. In this connection it should be remembered, also, that one of the committee of revision was the Hon. Geo. S. Boutwell, who was himself a prominent patent lawyer, and who would not be likely to use such terms without a clear understanding of the full import.

The final change in this Section occurred as follows. Soon after the completion of the revision, the Commissioner of Patents, Hon. S. S. Fisher, conceived the idea of amending the patent law. He took a copy of the revision as prepared by the Commission for the revision of the United States Statutes, and made in it such changes as he thought best,—cancelling with red ink such portions as were necessary, and, on blank leaves inserted in the pamphlet, wrote out the amendments or parts he wanted added. (One of the original copies thus prepared by him for the Committee on Patents, is still in my possession.)

In a consultation which I had with him at the time, he told me that his only idea of a change of the law relating to alien inventors was to place them on the same footing as American inventors, so far as the *fees* were concerned. He said: "We have put them on the same footing in the right to obtain patents and I think we should in regard to the fees. We have a large surplus in the Treasury, and therefore there is no longer any reason why we should exact from them these extra fees. In fact, I consider it very small business for a great Government like ours."

With that idea in his mind, the bill as prepared by him omitted these extra fees entirely; and the changes he made in Section 24 (now Section 4887) were to cancel the words "and common" before "use," and the words—"be limited to seventeen years from the date or publication of the foreign patent," and added in lieu of the latter, the words: "expire at the same time with the foreign patent, or if there be more than one, it shall expire at the same time with the one having the shortest term but shall in no case be in force more than seventeen years."

The only change intended to be effected by this amendment was to provide that where a foreign applicant had patented his invention in two or more foreign countries before applying in the United States—and which practice in recent years had become quite common,—his United States patent should expire with his shortest foreign patent.

This made the law definite and certain, whereas as it then stood, where a party had several foreign patents it was uncertain as to which of them should be used to fix the expiration of his United States patent. I know absolutely that he had no thought or intention of limiting the term of a patent to our own citizens who filed their applications in the United States first.

Nor was any such idea expressed by any one during the various hearings on the bill while before the House Committeee on patents. I was one of the committee of five appointed by the patent bar of Washington to look after the bill, and oppose certain features of it as drawn, more especially one which cut off the right of appeal from the decision of the Commissioner to the Court. We had several very full hearings, and I was present at various other times when the bill was being considered and discussed, and during all the time there was not a word of discussion or even a reference to that section or feature. We all understood that it would leave the law as it had always been construed, as applying the limitation to foreign inventors only.

As passed by Congress, it reads:—"No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years."

Thus, while changing the phraseology somewhat and adding the provision, "nor shall any patent be declared invalid," it left the section substantially the same as prepared by Commissioner Fisher, and bearing in mind the fact that the prior foreign patent was, as it had always been understood to mean, a patent taken by a foreigner in a foreign country first, the conclusion seems irresistible, that neither the Committee nor Congress had any thought of applying the limitation to the citizen inventor, and certainly not to the citizen, who filed his application in the United States in the first instance. But unfortunately the Supreme Court felt compelled to construe the words literally, and when so construed it includes the citizen inventor as well as the foreign inventor.

That the law as thus construed works a great wrong to American inventors, without any corresponding benefit to our own people, all agree; and it is to be hoped that it will be changed at the coming session of Congress.

It is a sad commentary upon the condition of affairs, that with all the litigation and efforts made, twenty-five years elapsed after the enactment of the section before the public could ascertain what the law really was. In the meantime hundreds of thousands of dollars, if not millions, had been invested in business supposed to be protected by patents which the decision of the Supreme Court wiped out of existence, and which that Court could just as well have decided years before as not.

CONCENTRIC WIRING.[1]—I.

BY SAM. MAVOR.

CONSIDERING the importance of the subject of electric light wiring, it does not seem to have an adequate share of the attention of this Institution. This is the more unfortunate as the tendency now is to allow the business of wiring to drift out of the hands of experienced electricial engineers into the hands of the legion of plumbers, gasfitters, and others who, often with small claim to the title, write "Electrical Engineer" upon their signboards. It is inevitable that wiring shall fall more and more into the hands of tradesmen of this class. They will follow more or less closely the methods of their predecessors, and defects in existing practice will thus be widely propagated. This is a question which seriously affects the whole industry, and hence the importance of this Institution setting an example by aiming at and endeavoring to secure a high standard of excellence in wiring work. It is a characteristic of the business of electric light wiring that it is peculiarly liable to the risks attending bad workmanship. Internal wiring—that is, the laying of insulated conductors in grooved wood casings, the jointing of these conductors, and the fixing of switches, fuses, etc.—is a comparatively simple matter. Apart from the distribution of lights and arranging the circuits and their routes, it is not work which must necessarily be done by a highly trained and skilled tradesman. For such work as the mason's, the bricklayer's, the joiner's, cabinetmaker's, etc., a man requires the training of a long apprenticeship, which entitles him to the wages of a skilled craftsman; but the mere laying of wires already manufactured in grooved wood casings erected by a joiner, and fixing ready-made switches on bases also prepared by the joiner, do not require the serving of a long and laborious apprenticeship. On the contrary, any man who can use his hands may, with very short experience, learn to joint wires and fix switches, and then call himself a wireman. The inevitable result is that such laborer can, and always will, be cheaply purchased. Much wiring work is really done by irresponsible amateurs of this kind, who are ignorant of the consequences which might result from their carelessness and lack of experience.

A further reason why electric light wiring is often not carried out by first-class labor lies in the intermittent nature of the employment. There are certain seasons of the year when the wiring contractor has little of such work, and must then discharge men. Indeed, wiremen are many times taken on at the beginning of a job and paid off at the end of it. Workmen of skill and intelligence soon find this out, and they seek employment in branches of the business where their qualifications find a better and more steady market. We all know how demoralizing it is for men to be idle for months at a time, and how apt they are to drift into lazy and careless habits. The diagram showing the number of 8 C. P. lamps connected to the Glasgow Corporation mains during each month from January, 1898, till the present time illustrates the fluctuations in the demand for wiring. You cannot expect a man to have a thorough interest and sense of responsibility in his work who knows that he will be paid off at the completion of the job. As wiring jobs often last only a few weeks, the poor wireman may have been in the employment of half-a dozen masters in the course of a season, with intervals of enforced idleness. In the case of joiners and plumbers and kindred trades, when outside work is slack, the men may be employed in the shop at preparing material or in manufacturing; but not so with the wireman. The material is all already prepared for him by skilled hands—his business is only to erect it. The larger firms who have a variety of electrical work can find employment for the best of their wiremen in other branches when internal wiring is dull. But they, too, when business is brisk, have to fall back upon the shiftless creatures who often present themselves as "wiremen." The proportion of "improvers" and apprentices employed at wiring is very much larger than in any similar trade.

The business—if it may be called a business—of electric light wiring has thus several features peculiar to it making for unreliable workmanship, which, in the absence of competent supervision and careful inspection, lead to defective work and resulting fire risk.

The plumber's and the gasfitter's work are to a great extent

1. Paper read before the Institution of Electrical Engineers.

self-testing. If a water pipe leaks we see the water, and if a gas pipe leaks we usually smell the gas; but we have no sense—no physiological sense—to enable us to find hidden defects in our electric wiring. A building may be wired in the most dangerously slipshod style, yet the lamps may for years burn none the less brightly, until the latent faults have opportunity to discover themselves.

Insulation tests after the completion of the work, if in dry and well-seasoned buildings, are of little value. The insulation tests of the wiring of an old building might show results three or four times higher than the most stringent rules require, and yet there might be a score of dangerous defects only awaiting opportunity to develop. No tests can be applied for the detection of these defects after the work is completed and covered in. On the other hand, in a new and damp building the insulation might be far below the requirements of the rules, and yet be absolutely safe. The important thing is that the work shall be carried out in such a style that the insulation attained shall be permanent, and tend to increase, rather than decrease, with time. Wiring has to be carried out in situations so different, and must comply with conditions so varied, that it is impossible to formulate rules which can in all cases be adhered to. Modifications must be allowed to meet special requirements, and the extent of these must be left to a great extent to the discretion of the contractor. That such discretion ranges over very wide latitudes is indicated by the large discrepancies between the tenders of different contractors for the same wiring work. When the prices of experienced contractors estimating for wiring work to a carefully drawn-up specification vary as we know they do, it is not strange that inexperienced contractors tendering in the absence of a specification, and without the prospect of any supervision, should quote prices which would not purchase suitable materials alone. These are matters of primary importance to the fire insurance companies, and they are much too lax in looking to their interests in this regard. Bad work is being carried out every day, and the insurance companies are complacently taking the risk. Several offices have issued wiring rules, and it is a very good thing for them to have rules; but what is the use of rules if they are not enforced? At present they are really only recommendations, and anyone who is so inclined may evade or ignore them. It is common knowledge that this is constantly done.

The present procedure of the insurance companies is most ingenuous. They send a schedule to the contractor who is carrying out the work—or, rather, who has done the work, for it generally arrives after the job is completed—and they then request the contractor to oblige them by giving replies to a list of questions. They receive the document filled up by the contractor, who has no responsibility beyond a moral one, and file it away, and presumably are satisfied that the thing is all right. They thereby exhibit a trust in human nature very flattering to the wiring contractor, but of the wisdom of which some of us may have our doubts. Until the insurance companies have organized a thorough system of inspection they will not have taken the steps necessary for their own protection. It seems to me that in every considerable town there ought to be a permanent official (in the pay of the fire offices collectively) whose duty it would be to inspect all electric light wiring while in course of erection, and to ruthlessly condemn defective workmanship or material. If such a staff of well-chosen, reliable and sufficiently well-paid inspectors were scattered over the country, they would soon put a stop to jerry work. The moral influence of their presence in the town would be a wholesome check upon the cheap-jack. The cost when spread over all the companies would be trifling, and would be amply repaid by the reduction of fire risk. The insurance companies already have one man in their collective employment in each of several of the larger cities. This man is an *attaché* of the Salvage Corps, and his duties are confined to the warehouse district. His functions are to familiarize himself with the positions of main switches, fuses, and cables, &c., in the warehouses with a view to his being of service to the Fire Brigade in case of emergency.

Before leaving this subject it may be noted that Lloyd's Register of Shipping some years ago issued a set of recommendations for the guidance of shipbuilders and owners in fitting electric light on their vessels; but, as they took no steps to ensure that effect was given to their suggestions, these remained a dead letter. The large number of electric fires on board ship during recent years, chiefly due to inferior work resulting from the practice of accepting the lowest tender, has impressed upon Lloyd's the imperative necessity for supervision. They have, therefore, issued a new set of rules, and they are now arranging for such a system of inspection as will ensure these rules being followed. The fire insurance companies would do well to profit by the dearly-bought experience of Lloyd's. If they do not, they will assuredly have to learn the lesson at their own expense. Although the insurance companies are primarily interested in this question of fire risk, the matter has a direct and important bearing upon the electric lighting industry. We must all recognize the desirableness of ensuring that wiring shall be carried out in a style which shall be fire-proof, electrically and mechanically good and durable, and shall not be offensive to the eye.

THE MORRIS-SALOM ELECTRIC CARRIAGE has been sold for shipment to Europe.

THE DUNN METHOD OF PREVENTING ACCIDENTS ON BROOKLYN BRIDGE.

Mr. Elias B. Dunn, head of the New York Weather Bureau, has devised a system of electrical signals for the purpose of preventing rear-end collisions on railroads. The recent accident on the Brooklyn Bridge suggested the device, and Mr. Dunn's plan is now in the hands of the board of trustees of the bridge. It is Mr. Dunn's plan to divide the bridge into eight sections, four on each side. A series of wires or a wire cable containing the necessary number of wires is run along the poles or uprights of the bridge and connected with the train despatcher's office at both ends, New York and Brooklyn. A box containing a switch and push buttons is placed on each or as many uprights as may be found necessary. In case of a stop for any cause or any accident, or when for any reason a train cannot leave on schedule time, the brakeman reaches out to the nearest pole-box, turns on the switch which lights up a line of red signal-lights, also placed on the poles or uprights, over the rear section. This notifies the train following that the track ahead is not clear. The brakeman on the second train repeats the operation on his section, which sets the signal on that section back of him, and thus the third train would be brought to a stop, the fourth, fifth, and succeeding trains being notified and stopped in the same manner. As soon as the first train is ready to resume its journey, the brakeman reaches out and turns the switch back to its original position, and in so doing extinguishes the lights back of him, which indicate to the train behind that the road ahead is clear. All the other section lights are extinguished in the same way around the bridge, and the road is clear. The plan is said to meet with the approval of several of the trustees, and may come up for consideration at the next meeting of the board.

DATA ON THE NEW YORK FIRE ALARM SERVICE.

Mayor Strong in his new year annual message reports as follows:—The records of the fire-alarm telegraph service show the following:

The entire number of street boxes is	880
In public schools	181
In city institutions	27
Making	1,088
Street boxes connected with underground system	497
Buildings connected with underground system	60
Public schools connected with underground system	30
Hospitals connected with underground system	5
Total	592

There are now in the subways 108¼ miles of cables, aggregating 964 miles of conductors; 26¼ miles of underground subsidiary ducts have been constructed by the department. It is important that the work of putting electrical conductors under ground should be continued, together with the finishing of the larger part of the uncompleted portion of the city south of One Hundred and Thirty-seventh Street.

The new Bureau of Electrical Appliances, having the enforcement of the law regarding the installation of electrical plants within buildings of the city, has been put into operation and systematized, and the work of inspection is being carried out, from which it is expected much good will come in preventing fires caused by poor workmanship in the installation of electrical appliances, which has been a great menace to life and property.

Concessions of an important character have been made whereby citizens may have auxiliary fire-alarm boxes placed in buildings where direct connections are required. By Chapter 247 of the Laws of 1894, without extortionate charges to the owners, a small contribution to our Relief Fund is secured, and good results are confidently anticipated.

FALL RIVER'S MAYOR AGAINST A MUNICIPAL PLANT.

In his New Year's message, the Mayor of Fall River advocated the giving of an opportunity for competition in the matter of electric lighting of streets, and recommends that early in the year the question of new contracts be considered and determined. He does not think it advisable for the city to construct an electric light plant. It means a large expenditure and the constant changes made necessary by improvements in electric equipment would call for continued expenditures, which will be much better provided for by private enterprise and capital for at least an additional five years. Underground wires are urged at the earliest moment.

POSITIONS TO BE FILLED.

An open competitive civil-service examination for the positions of steam engineer, electrical engineer and dynamo tender in the state institutions at Albany, Brooklyn, Buffalo, and Syracuse, on February 1.

LETTERS TO THE EDITOR.

POSTPONEMENT OF THE MEETING CALLED TO STANDARDIZE ELECTRICAL CONSTRUCTION RULES.

THE Committee on Standard Rules for Electrical Construction and Operation, of the National Electric Light Association, issued a call several months ago inviting the American Institute of Electrical Engineers, the American Street Railway Association, the National Board of Fire Underwriters, the International Fire Chiefs' Association, the American Institute of Architects, the American Bell Telephone Co., the Western Union Telegraph Co., the Postal Telegraph Co., the General Electric Co., and the Westinghouse Electric Co., to co-operate with their committee in the forming of a joint committee to consider generally the subject of electrical rules, with a view of securing the promulgation and enforcement of one standard set of rules for electrical construction and operation, and which set of rules would meet with the hearty approval of the various allied interests above referred to, as well as the world at large.

A call for this joint meeting was issued for January 18, 1896. It was subsequently deemed desirable, in view of the short amount of time in which to secure the co-operation of the various interests invited, as well as to do certain preliminary work prior to said meeting, that the date of the meeting be postponed until March 18, 1896, and notice of this change in the date was sent to each of the parties.

In view of the fact that this proposed meeting has been commented upon quite extensively through the electrical press, will you kindly call attention to the postponement.

It also affords me pleasure to state that nearly all the parties, who have been invited to send a delegate to this joint meeting, have already accepted and have sent me notification of their acceptance and the appointment of their representative. This is most encouraging. I have no doubt that the others will also act in accord in this important matter.

WILLIAM J. HAMMER,
Chairman Com. N. E. L. A.

NEW YORK, Jan. 7, 1896.

THE STANDARD LAMP BASE: WHICH SHALL IT BE.

Of late much has been said in regard to the adoption of a standard base for incandescent lamps. Too much in favor of this important point cannot be said. Some recommend one base and some another as preferable, presenting in most cases excellent reasons for their opinion. Let us, however, view the whole situation and not hold a small object so close to our eyes as to shut out the rest of the world. The mission of this article is to reach if possible a satisfactory conclusion of the lamp base situation.

The three bases considered are Edison, Westinghouse and Thomson-Houston. The latter is accepted as a practical and satisfactory device, which it really is, but inasmuch as these bases cost the manufacturer from $7 to $8 per thousand in excess of the two former, it seems this fact alone should be sufficient to omit it from further consideration, realizing that the interests of the manufacturer and consumer are identical.

The cost of producing Edison and Westinghouse bases are about equal, thus excluding the argument which condemned the Thomson-Houston base. To the electrical trade, it occurs to the writer but one, and only one, conclusion is self evident. It is a fact that there are a very much larger number of Edison type sockets in use and demand than Westinghouse. To adopt the Edison base would necessitate less change (which is synonymous with economy) than the adoption of any other. Other points of superiority in these two bases are so evenly divided, no objection can be raised from a mechanical standpoint to standardizing either. So it seems in conclusion, that the most practical and advisable plan is to at least consider the Edison base as the best adapted for a standard.

The advantages derived by manufacturers and supply houses would be immense and a complete stock under new conditions would be quite difficult enough to maintain, considering combinations of candle power, voltage, economy, finish and style, whereas under existing conditions it is impossible. After all, the execution of these arrangements rests alone with the consumer. The manufacturer, therefore, respectfully submits it to their judgment.

The fact, however, should not be lost sight of, that simplifying the method of producing and distributing is to lessen the cost of production.

OLIVER F. BRASTOW.

BOSTON, MASS.

THE AMERICAN SOCIETY OF CIVIL ENGINEERS hold its forty-third annual meeting here this week. Among the special places to be visited are the Crocker-Wheeler factory at Ampere and the United Electric Light & Power Co.'s new station in this city.

OBITUARY.

DR. J. W. ROGERS.

Dr. James Webb Rogers, who, as one of the chief promoters of the Pan-Electric Company, gained considerable notoriety, died recently at his residence in Maryland. He was born in North Carolina in 1822, was graduated from Princeton, studied law and subsequently theology. He was an Episcopal minister for twenty years. Later he became a Roman Catholic. The Pan Telephone syndicate scandal which involved so many prominent Democratic politicians during the first Cleveland administration was largely based on the Rogers "patents" and "inventions."

PERSONAL.

MR. W. L. MORGAN, who has been the assistant superintendent of the Beaver Valley Traction lines has gone to Sharon, Pa., where he is to take charge of the Sharon and Sharpsville Road.

MR. GEORGE M. KUEMMERLEIN has been appointed general superintendent of the Milwaukee Street Railway Co. and Mr. T. E. Mitten becomes his assistant.

MR. S. M. WHEELER has been appointed superintendent of the Jamestown Electric Light & Power Co. He is a Brush factory graduate of 15 years' experience.

MR. GEORGE TURNER has resigned his position as superintendent of the Marion, O., Electric Light and Power Co., and will now devote himself exclusively to the electric railway, with which he has also been associated.

MR. HORATIO A. FOSTER, the electrical engineer and mechanical engineering expert, has had so many engagements of late in Buffalo that he is compelled by the pressure of his work to establish himself in that city. He has opened offices at 18½ Swan Street, that city.

SOCIETY AND CLUB NOTES.

ALTERNATING CURRENTS AND ELECTRICAL RESONANCE.—DR. PUPIN BEFORE THE BROOKLYN INSTITUTE.

On Friday, Jan. 3, Prof. M. I. Pupin delivered a lecture on "Alternating Currents and Electrical Resonance" before the Brooklyn Institute of Arts and Sciences. The audience was large and evidently deeply interested in the subject of the lecture.

The lecturer reviewed briefly the reactions going on in an alternating current circuit and described the fundamental laws which govern these reactions, showing that they are formally the same as the laws governing the motion of an elastic body. Hence for every mechanical phenomenon there is an electromagnetic phenomenon resembling it in all its essential formal elements. This was illustrated by experiments on electrical resonance and long electric waves. Several of the experiments shown were never performed in public before and they form some of the results of investigations in which the lecturer had been engaged during last year, particularly the experiments on long electric waves. The wave shown in the lecture was about 800 miles long and was produced by an electromotive force of frequency about 600 periods per second.

The subject of resonance was illustrated by several interesting experiments; the most important among them were resonant analysis of complex harmonic currents and multiple telegraphy by resonance. Four messages were sent simultaneously and independently of each other over a line of 6,000 ohms. Resonant rise of potential was shown by vacuum tube discharges. There were 16 different tubes, showing 16 different discharges. In several of them the discharges were in the form of hollow vortex rings waving toward the extremities of the tube and also rotating at the same time about the direction of motion. A brief statement of the electromagnetic theory of light and the Hertzian experiments concluded the lecture which was very well received and highly commended by the local press.

BOSTON "POTENTIALS."

At the next meeting of the Electric Potentials of Boston, on Jan. 21, Mr. Addicks, engineer to the Bay State Gas Co. is to read a paper on Acetylene Gas, and in consequence of the universal public interest now being taken in this new illuminant all the prominent electricians and gas engineers throughout New England are expected to be present and take part in the discussion. At the following meeting the subject to be discussed will be the influence and result of recent legislation on electric light and power securities. The "Electric Potentials" is growing in popular favor and increasing in membership right along.

CHICAGO ELECTRICAL ASSOCIATION.

The Chicago Electrical Association held its third meeting for this season at 1737 Monadnock Building, January 3rd. The paper of the evening was by W. Clyde Jones on the "Protection of an Invention," and was a very concise and complete statement of facts regarding American patent laws and customs that cannot fail to be of interest to the numerous inventors in the electrical field. The discussion which followed was taken part in by W. R. Garton, Thos. G. Grier, S. B. Jamieson and others.

Following the paper the election of officers for the ensuing year was held and resulted in the election of W. Clyde Jones, patent attorney with Barton & Brown, president; S. G. McMeen, assistant engineer Central Union Telephone Company, Chicago, vice-president; J. R. Cravath, electrical editor *Street Railway Review*, secretary; F. S. Hickok, engineering department Western Electric Company, treasurer.

There has recently been a great increase in interest and membership of the Association, and it promises to take a prominent place among the local societies in the largest cities in the country. Electrical men around Chicago are cordially invited to attend.

HENRY ELECTRICAL CLUB.—MR. JOSEPH SACHS ON SWITCHBOARDS.

At the weekly meeting of the Henry Electrical Club, held on Jan. 10, Mr. Joseph Sachs lectured on the subject of "Switchboards." With the aid of lantern views and diagrams Mr. Sachs described the various forms of switchboards used in arc and incandescent lighting, and street railway work, explaining the distinctive features of each. He traced the evolution of switchboards from the days when any place in a station was thought good enough for switches, rheostats, etc., to the present time in which all such apparatus is mounted on panels of slate or marble. Among recent improvements was the shunt method of connecting ammeters, in which the instrument is actuated by a fraction of the total current. In that way it was possible to use one ammeter for several circuits. In switchboard design, he said, the most desirable points were arrangement of measuring instruments so that they might be readily seen; simplicity; few switch contacts and joints; and ease of access to all parts of the board.

He dwelt on the importance of low resistance connections and switch contacts. Loose screws and bad contacts meant just so much added to the coal bill. Because bus bars and switches were large it was a mistake to think their resistances negligible. Danger from short circuits could be obviated by proper arrangement of circuits and attention to insulation. Fire risks were reduced by the use of non-inflammable materials like slate and marble. The practice now was to construct all switchboards in that way.

The lecture on Jan. 17 will be delivered by Dr. Pupin on the subject, "Transformers."

TELEPHONE CONVIVIALITY IN NEW YORK.

The members of the Contract Department of the Metropolitan Telephone Company gave effect last week to a new practice in the conduct of the Department by celebrating their first annual dinner. The gathering was planned and carried out entirely by the members of the department, its chief, Mr. T. H. Mack, being a guest; and the results showed that they are as good hands at organizing a dinner-table circuit as they are at securing metallic circuit telephone contracts at the rate of several hundreds a month. Those who have any feeling of surprise at the remarkable growth of the Metropolitan system, which for the year 1895 attained an increase of 25 per cent. in number of stations connected, would have wondered no longer if they could have glanced around the private dining room of the Madison Avenue Hotel at the score and a half of intelligent active-looking young men who carry on the relations of the Metropolitan Company with the public in need of telephone service. The dinner was excellent and good fellowship was promptly established by the perusal of the name and menu cards which were couched in the form of an extremely witty parody of a telephone contract. Mr. U. N. Bethell and Mr. H. L. Webb shared with Mr. Mack the honor of being the Contract Department's guests for the evening and took occasion to compliment the assemblage on the fine showing it made individually and collectively, morally and physically, and on the admirable results of their negotiations among the New York public in so largely increasing the use and popularity of the telephone. After dinner an impromptu musical and dramatic entertainment was provided by the diners. The gathering was so successful as a whole and the pleasure of meeting out of office hours so thoroughly appreciated that it was unanimously felt that the dinner would have a long line of successors.

A largely attended dinner of a single department of a single telephone company is one of the sidelights that one occasionally gets on the magnitude of the telephone exchange industry—in which, by the way, New York leads.

LEGAL NOTES.

IMPORTANT DECISION ON TAXATION OF CONNECTICUT TROLLEY LINES.

The decision of the Connecticut Supreme Court in the New Britain trolley taxation case was handed down on Jan. 7. It is written by Judge Baldwin, and the other four judges of the court concur. The decision is regarded as mixed and ambiguous, counsel for the trolley companies, however, claiming that it is a partial victory for their side.

The court upholds the right of a municipality to exact compensation for damages by a trolley road, and says, in effect, that such compensation may take the form of a levy on gross receipts for that part of the road which is constructed after the municipal order is passed; but such tax does not apply to the gross receipts of a system of trolley roads already constructed. Counsel for the companies hold, however, that such compensation under the decision must be limited to actual and specific damages to be determined by equitable proceedings, and that the municipality cannot arbitrarily fix a tax under the guise of compensation.

The decision finds error in so much of the judgment appealed from as relates to the requirement of annual payments by the appellant of a percentage of its entire gross receipts and of annual returns of the amount of such receipts, and to the use of fenders and to the execution within a given period of a written acceptance of those other provisions, and a written agreement to fulfill them, and referring to the approval of a location on any part of any street which leaves the unused part of the highway of less than the width required by section 8 of the street-railway act of 1893. The rest of the judgment was affirmed.

The case was then remanded to Judge Fenn, to be amended in accordance with the decision.

The finding is regarded as a compromise of opinions in the court which has had many sessions on the subject, and points of the decision are almost certain to lead to further litigation.

The court holds that an express grant by the state of the right of a company to lay rails through certain specified streets is not dependent on the consent of the municipal authorities, who have, however, power to "modify" the plans of the company while not fundamentally altering them. Municipal authorities, for example, cannot compel the substitution of another motive power for electricity, but may require the substitution of a storage battery for the overhead trolley. The municipality can merely "modify," not change, essentials.

The court holds that any regulation of the municipality of New Britain must apply to new lines, not to lines which have been accepted under an old contract between the company and the municipality. At the same time it states that if the tax imposed upon the New Britain Company's gross receipts had been estimated merely with a view to a fair tax on the new lines, the tax would have been valid. But the tax, on the contrary, in the view of the court, seems to have been imposed with a view to compensation for repairing the streets through which the old lines run.

The right to impose fenders on street cars, the court says, belongs exclusively to the Railroad Commission of the state under a specific law.

The court passes the question of the additional servitude of trolleys on highways as entitling the abutting landowner to damages, on the ground that it is not relevant to the case, and also the question whether existing trolley lines may or may not be taxed if suit is raised in a different form from that of the New Britain case. On both these points there is a suggestion that a constitutional question may hereafter be raised.

A DETROIT DECISION AGAINST TELEPHONE SUBSCRIBERS' CONTRACTS.

A decision was handed down on Jan. 3, in Detroit, by Judge Carpenter, of the Wayne County Circuit Court on a petition by Henry C. Wisner, asking for a mandamus to compel the Bell Telephone Co. to place an instrument in his residence without his signing an objectionable contract, and also to have the court declare that the rate charged by the company was unreasonable.

In his opinion Judge Carpenter said that while the telephone company agreed, in Mr. Wisner's case, to allow him a telephone without signing a contract, the latter's refusal to accept the concession was justifiable, as he had already commenced proceedings for a judicial determination of the controversy, and was entitled to one. If a mandamus was issued in the case of Mr. Wisner upon the concession of the company, the court would thereby compel the granting of a privilege which may be rightfully denied to every other member of the community by the company.

"Respondent is engaged in a public business," said the court. "It has been permitted to occupy the streets of the city of Detroit and to furnish service of a public nature to the entire community. It can not, however, as can an individual engaged in a business of private concern, determine with whom, how or on what terms it will do its business. Organized to deal with the public, enjoy-

ing a public franchise, engaged in performing a duty of a public character, like railroad companies, express companies and telegraph companies, it owes such a duty to the public that some branch of the legislative department of the government may regulate its business and its charges. And in the absence of such regulations, it can not insist upon unreasonable conditions nor exact unreasonable charges. A remedy by mandamus is the appropriate one.

"We do not think respondent had a right to insist that relator should rent a telephone for more than a year, if he pays all the expense of putting it in and taking it out and reasonable compensation for the service he receives.

"The proposed contract restricts the use of said telephone to relator and his employés. The language "he shall not extend this use to other individuals except his employés" clearly indicates that except in the contingency of relator's wife and children being his employés, they have no right to use his telephone. It is clearly unreasonable to compel relator to procure several telephones to perform the service which can be performed by one.

"This provision is, therefore, in our judgment, unreasonable. The proposed special contract provides that the telephone shall "not be used for calling messengers except from the lessor (respondent) or performing any other service in competition with services which the lessor (respondent) may undertake to perform." It would clearly be as just and reasonable to require relator to order all his groceries or all his shoes from respondent.

"There is, in our judgment, both a practical and a constitutional objection to our making a determination. The court cannot say that a rate which to-day is reasonable will in six months from to-day be reasonable. The character of the service rendered, new inventions, a change in the rate of wages, or in the rate of interest, will affect the reasonableness of the rate. It is, too, the province of the legislative department of the government to fix rates which shall govern the future business of respondent and those engaged in similar undertakings.

"It is the province of the judicial department of the government to determine what shall be charged for services that have been rendered. If we should attempt to determine to-day what relator should pay respondent for telephonic service for the next year, it would be within the province of the legislative department of the government to establish a different rate, and thereby overrule our decision.

"Our inability to determine reasonable rates for the future can not, however, deprive us of power to determine this controversy. It is not disposed of until the compensation to be paid for the service compelled to be furnished is determined. Justice can be done both parties by issuing a mandamus and determining, after the service is rendered, by an investigation in this proceeding, what is a reasonable compensation. A mandamus, therefore, should issue, requiring the respondent to furnish relator telephonic services without requiring him to execute the proposed special contract. A reasonable compensation must be paid for this service. If the parties hereto cannot agree, either may apply to this court at the end of every three months, or at any other time that relator discontinues the use of his telephone, to determine what shall be paid for the service which at that time respondent has furnished relator by virtue of this order."

All the Wayne circuit judges concurred in the decision.

VAN DEPOELE UNDERRUNNING TROLLEY—A REHEARING AND AN INJUNCTION DENIED.

In the United States Circuit Court at New Haven on Jan. 11, Judge Townsend has refused a rehearing of the under-running trolley case of the Thomson-Houston Electric Company against the Winchester Avenue Railroad Company. He denied an injunction against the Westinghouse Company, as it did not appear as a party to the suit.

JUDGE COXE'S TROLLEY SWITCH DECISION PARTLY REVERSED.

In the suit of the Thomson-Houston Electric Co. vs. the Elmira and Horseheads Railway Co., involving the trolley overhead switch patent of Van Depoele, the Circuit Court of Appeals has rendered a decision partly reversing that of Judge Coxe which sustained the patent. The new decision, however, is alleged to invalidate three of the minor claims and to leave the main broad claims in full force.

NEWSPAPER CABLE MESSAGES TO THE PRINCE OF WALES AND OTHERS WERE IN VIOLATION OF LAW.

State Department officials call attention, in connection with recent telegrams addressed to the Prince of Wales and others, to the following provision of the Revised Statutes taken from a law passed as long ago as Jan. 30, 1799, and still in full force and unrepealed:

"Section 5,335.—Every citizen of the United States, whether actually resident or abiding within the same, or in any foreign country, who, without the permission or authority of the Government, directly or indirectly commences or carries on any verbal correspondence or intercourse with any foreign Government, or any officer or agent thereof, with an intent to influence the measures or conduct of any foreign Government, or of any officer or agent thereof, in relation to any disputes or controversies with the United States, or to defeat the measures of the Government of the United States; and every person being a citizen of, or resident within, the United States, and not duly authorized, who counsels, advises, or assists in any such correspondence, with such intent, shall be punished by a fine of not more than $5,000 and by imprisonment during a term not less than six months, nor more than three years; but nothing in this section shall be construed to abridge the right of a citizen to apply, himself or his agent, to any foreign Government or the agents thereof for redress of any injury which he may have sustained from such Government, or any of its agents or subjects."

The subject of the cable messages sent by the *New York World* to the Prince of Wales, Duke of York and other eminent persons in England, in regard to the Venezuelan boundary dispute, was brought up in Congress last week, with special reference to the above clause; but the conclusion reached was that good rather than harm had been done in promptly eliciting friendly sentiments, and the matter was dropped without any action being taken.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED DEC. 31, 1895.

Accumulators:—

Electric Battery, D. S. Williams, Philadelphia, Pa., 552,218. Filed July 19, 1895.

A storage battery involving novel construction and combination of the supports for the positive and negative discs of active material.

Electrical Battery, D. S. Williams, Philadelphia, Pa., 552,219. Filed Aug. 23, 1895.

A storage cell in which a single positive electrode is employed in connection with a large number of separate blocks forming a negative electrode.

Electric Battery, D. S. Williams, Philadelphia, Pa., 552,220. Filed Aug. 23, 1895.

The individual cells are combined in a single receptacle so as to give a high voltage.

Secondary Battery, A. S. Krotz and W. W. Spencer, Springfield, O., 552,222. Filed Jan. 31, 1895.

The active material is retained within sheets of porous material.

Secondary Battery, C. A. Faure, Paris, France, and F. King, London, Eng., 552,425. Filed March 6, 1895.

The active material is held against the plate by a sheet of silicated asbestos over which is placed a perforated envelope of ebonite or celluloid.

Alarms and Signals:—

Keyless Fire Alarm Telegraph Box, N. H. Suren, New York, N. Y., 552,153. Filed Mch. 8, 1895.

The local or box alarm will not sound until the handle has been turned far enough to trip the mechanism and set it in operation beyond the further control of the operator.

Electrical Railway Signaling Apparatus, H. J. Hovey, Evanston, Ill., 552,181. Filed Aug. 5, 1895.

Electric Signal for Railways, E. B. Cutten, New York, N. Y., 552,279. Filed Apl. 1, 1891.

The signals are given in the locomotive cab.

Electrical Railway Signaling System. T. B. Dixon, Henderson, Ky., 552,316. Filed July 10, 1894.

Conductors, Conduits and Insulators:—

Insulating Joint, E. P. Gleason, Brooklyn, N. Y., 552,363. Filed Dec. 27, 1894.

In an insulating coupling the combination of two tubular and flanged portions, the faces of said flanged portions being at substantially at right angles to the length of the tubular portions, a fastening device, consisting of a ring on the outside of the flanges and covering them and the plugs, the insulating material and plugs of insulating material extended through holes in the flanges.

Insulator, C. H. Snively, Mount Carmel, Pa., 552,501. Filed Mch. 20, 1895.

The combination with suitably supported insulator blocks, of means for simultaneously clamping the wire between the blocks and stretching the wire.

Dynamos and Motors:—

Synchronous Single Phase Motors, C. E. L. Brown, Baden, Switzerland, 552,318. Filed Feb. 6, 1893.

A motor consisting principally of two parts, a fixed winding bedded in iron directly connected to the mains, and a second rotating winding also bedded in iron and connected with two collectors. Of these one has a considerable number of segments while the other is simply a collector with an equal number of segments as the machine has poles.

Electric Motor, A. W. Smith, Washington, D. C., 552,337. Filed July 23, 1895.

An alternating motor involving a commutator and special winding.

Electro-Metallurgy:—

Electric Smelting Furnace, J. A. Vincent and J. E. Hewes, Philadelphia, Pa., 552,341. Filed July 18, 1895.

In an electric smelting furnace, the combination of the hearth, with a removable bottom constituting one of the electrodes, an adjustable electrode arranged above the bottom and movable vertically, and feeding devices at the upper part of the hearth or furnace for delivering the materials to be smelted into the hearth.

Galvanic Batteries:—

Depolariser for Primary Batteries and Method of Making Same, G. W. Thurnauer, Aurora, and M. M. Kohn, Chicago, Ill., 552,311. Filed Feb. 20, 1895.

As a new article of manufacture, a depolarizing plate consisting of copper oxide intermixed with copper chloride, the whole forming a compact solid mass.

Lamps and Appurtenances:—

Electric Arc Light, L. B. Marks, New York, 552,190. Filed Oct. 9, 1894.

An arc lamp having a transparent or translucent inclosure around the arc, provided with a small inlet for air and ducts for leading the air in a uniform direction relatively to the arc.

Electric Arc Incandescent Lamp, J. A. Mosher, Chicago, Ill., 552,498. Filed Sept. 23, 1895.

In a composite carbon for electric arc lamps all portions of which are combustible and electrically conductive, the combination with a core, of a body portion super-imposed thereon and being, relatively, as to the core, of high combustibility and low electric resistance.

Measurement :—

Electric Meter, J. R. Tucker & C. C. Hinckley, Aurora, Ill., 552,309. Filed Mch. 25, 1895.
Consists in connecting a recording device with an ammeter in such a manner that the length of time during which the recording device is operated in any given period will depend upon and vary with the current in the circuit.

Miscellaneous :—

Multipolar Electromagnet, W. P. Daniels, Cologne, Germany, 552,103. Filed Sept. 7, 1895.
A lifting magnet provided with a multiplicity of sliding pole pieces adapted to conform to uneven surfaces.
Electric Thermostat and Push Button, O. F. Woodward, Le Roy, N. Y., 552,166. Filed Dec. 29, 1893.
Combines in a single instrument an electric push button and thermostat, and in some instances a call-bell.
Apparatus for Transforming Alternating Currents Into Uni-Directional Currents, O. Pollak, Frankfort-on-the-Main, Germany, 552,260. Filed May 22, 1893.
A commutator for charging storage batteries from alternating circuits, constructed so as hold the electrical connections between the commutator segments and the commutator brushes open while the current impulses are below a predetermined potential but higher than zero, and closed while said impulses are above such potential.
Electrical Bicycle, O. Bolton, Jr., Canton, Ohio, 552,271. Filed Sept. 19, 1895.
The armature is mounted directly on the shaft of the rear wheel
Apparatus for Purifying Feed Water, S. G. Cabell, Washington, D. C., 552,412. Filed May 26, 1894.
Apparatus for electrolyzing the feed water.
Apparatus for Purifying Water by Galvanic Action, S. G. Cabell, Washington, D. C., 552,413. Filed Feb. 15, 1895.
Similar to above
Galvanic Feed Water Purifier, S. G. Cabell, Washington, D. C., 552,414. Filed Oct. 16, 1895.
Electric Gas Lighter, P. Meyer, Alameda, Cal., 552,384. Filed Sept. 20, 1895.
Adapted to burners of the Welsbach type.
Engine Stop, J. Brady, Brooklyn, N. Y., 552,462. Filed Feb. 14, 1895.
Improvement on Patent No. 506,229.

Railways and Appliances :—

Apparatus for Automatically Maintaining Current upon Moving Vehicles, H. B. Dey, Brooklyn, N. Y., 552,105. Filed May 20, 1895.
A storage battery energized from the motor dynamo and adapted to actuate the latter and energize the motor circuit upon a cessation of the main supply.
Electrical Rail-fish, V. Thelin, Geneva, Switzerland, 552,338. Filed Aug 1, 1895.
The rail bond carries a thimble which is inserted into a hole in the rail and expanded by a taper pin.
Motor-Suspension for Street-Cars, G. F. Card, Mansfield, O., 552,347. Filed Aug. 21, 1895.
The combination with a motor, of a frame having one end elastically supported upon the car truck, and the other end elastically from the car axle, and a pivotal connection of the motor and frame between the points of support of the frame.
Means for Operating Electric Railway Vehicles. E. G. W. C. Hoffman, Charlottenburg, Germany, 552,369. Filed Sept. 3, 1895.
Relates to the construction of a car controller.
Electric Railway, M. H. Smith, Halifax, Eng., 552,451. Filed Oct. 26, 1887.
In an electric railway system the combination with the main conductor, of the sectional surface bar conductors having extended poles pieces, and a magnetic switch comprising a pivoted lever carrying an armature for the pole pieces and carrying a contact piece for the main conductor.
Rail-Bond for Electric Railways, B. J. Jones, Chicago, Ill., 552,477. Filed Mch. 29, 1895.
The bond is of V-shape and occupies a vertical plane between the web and the fish plate.
Electrical Rail Bond, M. K. Kendall, Melrose, Mass., 552,479 Filed Aug. 12, 1895.
Consists in forming a series of cross slits in the bond, placing the bond with the centre of the cross-slits opposite bolt-holes in the web of the rail, and driving a bolt or pin into the bolt hole.

Regulation :—

Regulator for Dynamos, C. E. Scribner, Chicago, Ill., 552,397. Filed June 1, 1889.
Consists of means for altering the current connections of a multiple wound field magnet.
Regulator for Electrical Circuits, J. C. Mayrhofer, New York, 552,495. Filed July 5, 1895.
In an electric regulator, the combination with a resistance coil, of a series of commutator plates connected at intervals with said coil, circuit connections from the opposite ends of the coil independent of the commutator, and two contacts having circuit connections movable over the commutator, whereby different circuits may be regulated independently or together in the same or opposite directions.
Electric Lighting System, J. C. Mayrhofer, New York, 552,496. Filed July 5, 1895.
Object is to provide apparatus for the regulation and control of the electric lights in a theatre, whereby in a simple and effective manner the different colors and intensities of light desired can be secured.

Switches, Cut-Outs, etc.:—

Automatic Electric Switch, H. H. Blades, Detroit, Mich., 552,094 Filed Sept. 14, 1895.
A motor switch. Improvement on patentee's previous inventions.
Safety Device for Electric Circuits, P. H. D'Unger, Chicago, Ill., 552,239. Filed Sept. 16, 1895.
The circuit is opened by the explosion of a material fired by a spark from the secondary of an induction coil, the primary of which is placed in the main circuit.

Telephones :—

Electric Telephone, S. D. Field, Stockbridge, Mass., 552,173. Filed Aug 5, 1895.
Produces a transmitted circuit current somewhat analogous to that employed in cable "curb" signaling, in the case of the telephonic current, shortening or degrading the heavier pulsations created by heavy tones, and accentuating or magnifying the finer vibrations and harmonics. Employs device shown in patent No. 552,172.
Signaling and Lock Out Apparatus for Telephone Stations, J. D. Clarke, Chicago, Ill., 552,420. Filed April 5, 1895.
Details of construction.
Double Diaphragm Telephone Transmitter, D. Drawbaugh, Eberly's Mill, Pa., 552,469. Filed Feb. 23, 1895.
A microphone transmitter having two diaphragms which are acted upon simultaneously by the voice impulses.

Telegraphs :—

Electromagnetic Mechanism, S. D. Field, Stockbridge, Mass., 552,172. Filed Aug. 5, 1895.
An adaptation of Houdin's compensating levers to avoid friction between the colliding surfaces in contact in an armature and magnet.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JAN. 7, 1896.

Alarms and Signals:—

Apparatus for Protecting Electrical Circuits, J. M. Oram, Dallas, Tex., 552,542 Filed June 4, 1895.
When one transmitter makes the alarm-circuit the second transmitter, if in unison, breaks said circuit, and vice versa, and any failure in substantially accurate correspondence of unison results in indicating such failure.
Phase Completing Device, J. F. Sibley, Clinton, Canada, 552,553. Filed Mch. 23, 1893.
The phase-completing device is locked and retained in position while the arm is withdrawn to complete its backward movement, and releasing devices actuated by the next forward movement of said arm an equal distance throw out the locking devices and release the phase-completing device.
Automatic Electric Alarm, T J. Stansel, Laredo, Tex., 552,733. Filed June 1, 1895.
An automatic hotel guest call.
Local Alarm Door for Signal Boxes, F. W. Cole, Newton, Mass., 552,746. Filed Mch. 9, 1895.
A local alarm is given before the fire alarm can be transmitted.
Electric Signal Tag, F. G. Pratt, Revere, Mass., 552,776. Filed Aug. 20, 1894.
An arrangement of relays and their circuits as to require the closing of the circuits in a certain definite predetermined order, before the signal circuit proper can be closed so as to clear the signal after it has been shifted to danger.
Automatic Electric Alarm, G. B. Williams, Texarkana, Tex., 552,803. Filed Apl. 8, 1895.
For use in connection with automatic sprinkler system.

Dynamos and Motors :—

Electric Motor, S. D. Field, Yonkers, N. Y., 552,521. Filed June 27, 1892.
The combination with the motor frame carrying the field magnets, the armature, and brushes mounted in fixed relations to the field magnets of a support for the motor frame whereby the motor frame may be partially rotated without changing the relations of the brushes to the line of commutation.
Electric Motor, G. L. Thomas, New York, 552,858. Filed Mch. 19, 1895.
Gas is produced under pressure by electrically heating a voltaic fluid in a closed vessel, which gas is caused to actuate a motor, whence it passes to a condenser, where it is reliquefied and returned to the generator.

Lamps and Appurtenances :—

Electric Arc Lamp, W. S. Bartholomew, Chicago, Ill., 552,874 Filed Sept. 23, 1895.
Relates to the construction of the frame of the lamp, and particularly to the manner of securing the carbon holders and of guiding the carbons.

Measurement :—

Electric Meter, W. H. McGrath, Fort Wayne, and J. M. Oram, Dallas, Tex., 552,540. Filed July 8, 1895.
A clock meter which registers the time the apparatus has been in operation.
Electric Gas Lighting Burner, J. E. Swendeman, Boston, Mass., 552,594. Filed June 7, 1895.
The wiper is brought below the fixed electrode after each ignition.

Miscellaneous :—

Valve Controlling Device, J. F. Batchelor, Brooklyn, N. Y., 552,811. Filed July 23, 1895.
In a valve controlling device, the combination with a main balance valve of an auxiliary valve having a valve stem carrying a perforated slide valve, and a disc valve adapted to simultaneously control the supply and exhaust pressure to one side of the main valve and means to operate said auxiliary valve.
Instrument for Treatment of Strictures by Electrolysis, J. A. Fort, Paris, France, 552,832. Filed Nov. 7. 1895.

Railways and Appliances :—

Electric Railway System, H. Brandenburg, Chicago, Ill., 552,604. Filed Oct. 5, 1894.
The live conductor is completely sealed and shielded from moisture and is in circuit with the trolley wire only at the point of contact between such wire and the trolley.
Trolley, B. Dale, Milwaukee, Wis., 552,631. Filed May 9, 1895.
Self adjusting bearing spindles of peculiar construction, whereby the wear will be automatically compensated for.
Conduit System for Electric Railways, C. A. Gaines, New York, 552,755. Filed May 1, 1894.
Details of construction.
Motor Vehicle for Single Rail Elevated Railways, Fritz B. Behr, London, England, 552,812. Filed Sept. 26, 1895.
The combination of the two axles of the two driving wheels, carried by a separate wheel frame and extending from such wheels to opposite sides of the carriage, two motor engines, means for transmitting the motion of the motor engines to the wheel axles, and further describing details of construction.

Regulation :—

Electric Circuit Controller, H. A. Gorn, New York, 552,756. Filed July 26, 1895.
An automatic switch for elevator motor control.

Switches, Cut-Outs, Etc :—

Electric Switch, S. Bergmann, New York, 552,574. Filed Apl. 23, 1895.
A compound revolvable ratchet device of insulating material, having two complete ratchet-faces lying in different general planes, each having alternate conductive and non-conductive portions.
Junction Fuse and Switch Box, W. F. Bossert, Utica, N. Y., 552,658. Filed Apl. 3, 1895.
Electric Cut-Out and Insulator, H. A. Wagner and F. Schwedtmann, St. Louis, Mo., 552,580. Filed Jan. 21, 1895.
For description see page 63 this issue.

Telegraphs :—

Printing Telegraph, J. E. Woodbridge, Duluth, Minn., 552,788. Filed Oct. 7, 1895.
Improvements on the inventor's previous patent No. 549,179.

Telephones:—

Telephone Switch, G. W. Coy, Milford, Conn., 552,516. Filed March 15, 1895.
All the necessary switching is done by means of the transmitting apparatus instead of being done as heretofore, by means of the receiver.
Telephone Transmitter, I. J. Kusel, St. Louis, Mo., 552,689. Filed April 29, 1895.
Details of construction.
Telephone Switch, G. W. Coy, Milford, Conn., 552,705. Filed April 5, 1895.
Same object as above.
Multiple Switchboard for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 552,723. Filed March 5, 1892.
Object is to provide apparatus for indicating to the operator primary signals from a calling line; so constituted as to fail to respond to signals subsequent to the establishment of connection with the line, and to accomplish this without including contact-points in line circuits.
Multiple Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 552,724. Filed Mch 17, 1893.
An electric annunciator provided with two independently pivoted armatures, one armature carrying a hook or detent adapted to engage with and retain the other armature, which serves as a drop or target, the armature carrying the hook being adapted to be operated by a less current than is required to operate and retain in position the armature which serves as a target.
Spring Jack for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 552,725. Filed July 30, 1892.
Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 552,726. Filed Apl. 26, 1893.
The annunciator is rendered irresponsive to signaling currents during the existence of a connection with its telephone line.
Annunciator for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 552,727. Filed May 2, 1893.
Responds to signaling currents of rapidly alternating character, but remains inert to continuous currents.
Multiple Switchboard, C. E. Scribner, Chicago, Ill., 552,728. Filed June 1, 1889.
Relates to a busy test on single cord multiple switchboards.
Spring Jack Switch, C. E. Scribner, Chicago, Ill., 552,729. Filed May 9, 1893.
Telephone Circuit, C. E. Scribner, Chicago, Ill., 552,730. Filed June 16, 1893.
Two induction-coils whose primary helices are connected with the same microphone and whose secondary helices are connected in series in the line-circuit; the telephone receiver is in shunt with the secondary helix of one of the induction coils.
Telephone Circuit, Charles E. Scribner, Chicago, Ill., 552,730. Filed June 16, 1893.
In combination, a microphone included in a local battery circuit, two induction coils having their primary helices connected in circuit with the microphone, and their secondary helices in series in a telephone line, and a telephone receiver in shunt or parallel circuit with one of the secondary helices, the object being to avoid side tone.
Telephone Switchboard and Circuit, T. C. Wales, Jr., Boston, Mass., T. Spencer, Philadelphia, Pa., 552,734. Filed July 25, 1895.
Relates particularly to a test circuit in centralized battery systems.
Trunk Line for Telephone Exchanges, T. C. Wales, Jr., Boston, Mass., 552,735. Filed Aug 24, 1895.
Applicable particularly to those switching systems in which calls received at an annunciator-board, where all line annunciators are placed, are distributed by means of trunk lines to different operators at switchboards.
Telephone, N. L. Burchell, Washington, D. C., 552,816. Filed Oct. 29, 1895.
An electric lamp is automatically lighted by the same movement that raises the receiver and transmitter.
Telephone System, F. R. Colvin, New York, 552,833. Filed Feb. 2, 1895.
For coupling subscribers' circuits and permitting the central office operator to hear and converse with both connected subscribers without disturbing the relations of their circuits.
Telephony, F. R. Colvin, New York, 552,865. Filed Jan. 14, 1895.
For description see page 69 this issue.
Telephone Switch, G. W. Coy, Milford, Conn., 552,866. Filed April 1, 1895.
All the necessary switching is done by means of the transmitting apparatus instead of being done as heretofore by means of the receiver.
Desk Telephone Apparatus, G. W. Coy, Milford, Conn., 552,867. Filed Apl. 1, 1895.
Similar to above.

THE PLAGUE OF MODERN IMPROVEMENTS—IN ENGLAND.

MR. HARRY FURNISS delivered himself of the following indictment in the *London Times*:—

"My experience in the last few weeks of the modern inventions which are designed to facilitate business and to benefit the public generally is, I think, worth recording, as I seriously question if these wonderful inventions and the extra expense incurred by adopting them are not a mistake. The working of the telephone has become, of course, a farce, and the sooner the Government takes it up the better. Several large business houses have given it up, and London, which ought to be the most favored, is probably the most unfortunate city in the working of the telephone of any in the world. I have tried half-a-dozen times in one day to ring up different people on the telephone without succeeding in getting through, and have had to send notes by hand. The electric light is another disappointing 'improvement.' Recently it has, in my own experience, gone out four times in one week, and we have had to use candles and lamps. Then there is the District Messengers' wire, which I have in communication with my house. I ring up for a cab; no response. I ring up again; nothing comes. I send out for a cab, and am late to dinner. The next day a representative calls casually to inform us that we cannot use the wire for two or three days, as something has gone wrong. I am now trying the phonograph; but, although at present I have had more correspondence about it than I have had through it I live in hope that I may find it worth the three years' trial the Company asks one to sign for. Altogether, it is a question whether paying rental for all these things, and then having, through their failure, to go to greater expense, is absolutely advantageous, and whether the story of the driver of the old stage coach who, when railways were introduced, remarked to a passenger, 'Well, all I can say is that if a coach comes to grief—well, there you are; but if there is an accident on the railway, where are you?' might not be very well applied to those experiments in the advancement of science intended to facilitate our work and add to our comfort. The electric light kills our sight; the telephone destroys our temper; the district messenger call ruins our dinner; and, conjointly, they waste our time and deplete our purses."

TO CONTRACT FOR A HAWAIIAN CABLE.

SENATOR HALE has introduced a bill in the U. S. Senate authorizing the Postmaster-General to contract with the Pacific Cable Company for the construction of a telegraph cable between San Francisco and Honolulu, Hawaii. The United States is to pay the company annually a sum equal to 4 per cent. of the amount expended each year by the company. The contract is to continue for twenty years, and the line is to be completed by July 1, 1897. It is also stipulated that the Government may come into the ownership of the proposed line by paying the cost price for it with 5 per cent. added.

CAMBRIDGE, MASS., MUNICIPAL LIGHTING PLANT.

The passing in the Cambridge Common Council of the resolution taking the property of the Cambridge Electric Light Company for municipal use means that the question will go to the people for final action. The purchase of this plant means an expenditure of $500,000 on the part of the city. This amount will probably be raised by issuing bonds.

Mayor Bancroft's signature is all that is needed before the people vote upon it at a special election. The mayor has not yet decided whether to sign or not. Many prominent citizens are endeavoring to persuade him against it. Prof. Agassiz, the celebrated naturalist, a large property holder, has announced his resolve to sell out and move to Newport if a municipal plant is started.

NEW HOPE IN ELECTRIC LIGHTING AT BRAINERD, MINN.

The municipal electric light plant at Brainerd was a failure, and the people recently voted overwhelmingly in favor of selling it, in order that they might save taxes and get a good service. Articles of incorporation of the Brainerd Traction, Light and Power Company have now been filed in Chicago, the stockholders being C. N. Parker, of Brainerd; E. C. Gibson, of New York city; P. A. Gibson, of Erie, Pa.; Fred S. Parker and W. S. McClenahan, of Brainerd. The officers are: C. N. Parker, president; E. C. Gibson, vice president; P. A. Gibson, secretary and treasurer; Fred S. Parker, manager; H. D. Freglawny, assistant secretary and treasurer. The company will have experienced men on the ground to make estimates on improvements in the electric light plant and water power, and will at once begin active work. From $10,000 to $15,000 will be spent in improvements at the lighting station. The plants included in the deal are the Brainerd Electric Railway Company, Brainerd water power, the electric lighting plant, owned by the city, and the Brainerd telephone system. This means much for Brainerd, and no stone will be left unturned that will lend a helping hand to the success of the enterprise.

SUDDEN DEATH OF MARCUS MARX.

Mr. Marcus Marx, vice-president of the Drawbaugh Telephone & Telegraph Co., of New York city, died suddenly on Monday last in the lobby of the New York Times Building whither he had been carried from the sidewalk. Mr. Marx came to this country from Germany when young and engaged in the glove business in which he amassed a fortune. Of late years he had devoted his energies to the Drawburgh Company.

THE MANAGEMENT OF "ELECTRICITY."

Mr. B. E. Greene, editor of "Electricity," has retired from the management of that paper and hereafter, including this week's number, "Electricity" will be issued under the direction of Mr. Edward Weston, electrician of the Weston Electrical Instrument Company, of Newark, N. J., who has associated with him Mr. C. D. Shain, eastern agent of Siemens & Halske.—*New York News Bureau.*

WESTERN NOTES.

L. A. BAKER & Co., Elgin, Ill., have now in their employ Mr. H. L. Willis, formerly an electrical engineer for the C. & C. Electric Co., and are prepared to do all kinds of electrical work and repairs on dynamos and motors in addition to their other business.

WEST CHICAGO.—Specifications for digging the trenches and laying the underground conduit, and making manholes and setting the lamp poles for the electric wires of the plant for illuminating the West Chicago system of parks and boulevards are now being got ready, and it is expected that work on this will be commenced very shortly, and when completed, the West side will have as fine boulevards as those already on the North and South sides of the city.

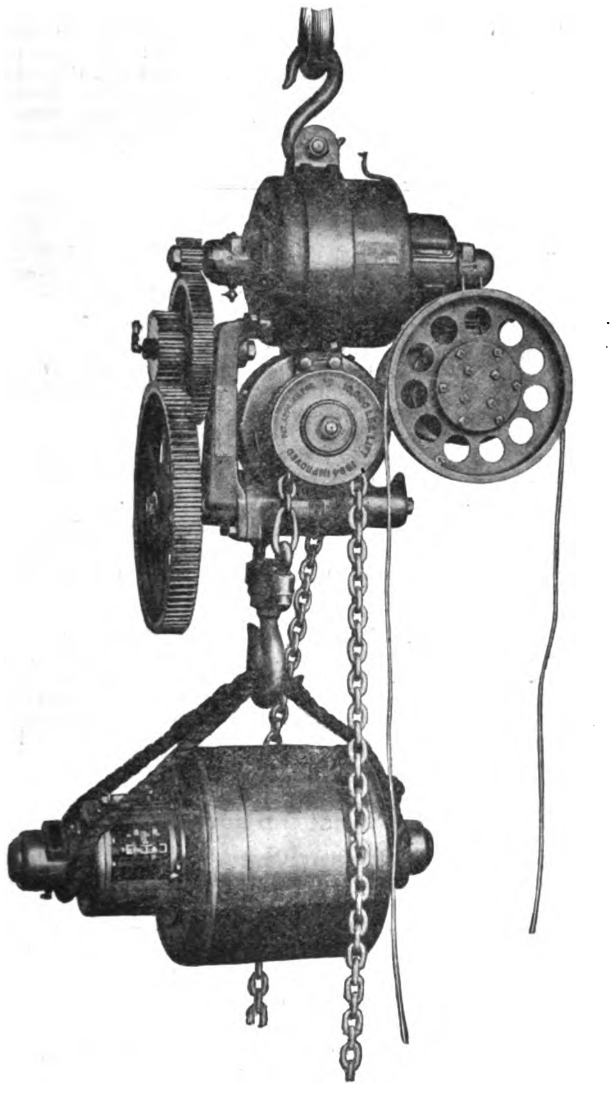
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

STOREY MOTOR CHAIN HOIST.

ONE of the many new departures in the line of direct-connected apparatus is shown in the chain hoist here illustrated, which is a very useful piece of machinery especially in electric light and power stations, iron and steel foundries, factories, etc., and for handling heavy freight.

This is another of the ingenious products of the Storey Motor & Tool Co., and the type illustrated is of 10,000 pounds capacity. This hoist is operated by a 5 H. P. motor and will lift 10,000 pounds 5½ feet per minute and lighter loads proportionately faster. It will lower at the rate of 10 feet per minute. By means of the



STOREY MOTOR CHAIN HOIST.

reversing controlling box which comprises a part of the apparatus, the hoist will raise and lower anywhere within the above speeds at the will of the operator. The starting, stopping, regulating and reversing of the motor is controlled by the two ropes shown which are connected to a wheel on the reversing rheostat, which is automatic in its action, the current being cut off as soon as the rope is released.

WIRE WOUND COPPER PIPE FOR HIGH STEAM PRESSURES.

THE two 12-inch wire wound copper pipes, made by the Quintard Iron Works, and referred to in last week's issue, were made to suit the requirements of the New York Edison Illuminating Company in regard to strength. While the winding of copper pipe is no longer a real novelty, we believe the system of winding in the present case to be so. After the usual manufacture and test of the pipe, the latter is closely served, by a winding apparatus, with annealed drawn steel wire and fastened by special means at suitable distances apart.

The usual method of serving is to use wire rope (both copper and steel) and securing it with various styles of hitches which of course make a great number of kinks in the serving and thereby greatly reducing the strength of it. Among the advantages to be obtained from the use of wire winding for the pipe, may be mentioned, that the copper is not subjected to any more than the usual amount of working, harmful local heating of the copper is avoided, and the greatest strength of the steel wire is obtained without its strength being injured either by working or securing.

ELECTRA CARBONS USED BY THE NEW YORK EDISON CO.

The New York Edison Co., is noted for the care which it bestows on its equipment and the rigor with which it examines and tests all supplies before acceptance. An article adopted by them is therefore a safe guarantee of excellence and a much sought for distinction. The "Electra" Nürnberg, carbons, for which Hugo Reisinger, of New York, is agent, have been adopted by the New York Edison Co., after a severe test in which, we understand, they were pitted against a number of others. This ought to be a sufficient testimonial of their superior quality which will not be lost on central station managers.

CHICAGO CYCLE SHOW.

That the bicycle show which took place last week in Chicago was an immense success, must be apparent not only to any one of the many thousands who attended it, but also to the countless numbers of those who not being able to go there in person perused the Chicago papers at that time. It was computed by the most conservative people interested in this immense industry that upwards of $5,000,000 worth of business would be placed at the show during the week, while others of a more sanguine temperament estimated that it would amount to more than twice that sum. Tattersall's great show building on 16th street being found inadequate to the wants of the exhibitors, two floors of the neighboring Jonathan Clark building on State and 16th streets had to be taken in as an auxiliary.

There were some 200 exhibitors of bicycles and everything pertaining to this great and still growing business.

The decorations of the buildings and spaces were on a most elaborate scale, the furnishings of the booths being very rich and tasteful; and many of the electrical signs and devices were so handsome as to make the tout ensemble remind one of the days of the World's Fair.

It is estimated that the value of the exhibits amounted to upwards of $500,000. The total expenditure in lighting and decorating the buildings was $35,000 which did not include the decorations and lights used in the individual booths.

In the lighting 200 arc lamps and over 5000 incandescent lamps were used, and this part of the display attracted fully as much of the attention of the crowds that thronged the buildings as the bicycles which were on show. Among the exhibitors were several well known in the electrical business inclusive of the following: Adams & Westlake, Julius Andrae & Sons Co., Prentiss Tool & Supply Co., Garvin Machine Co., Lodge & Davis Machine Co., Newton Rubber Works, Cycle Electric Light Co., Independent Electric Co.

The Chas. E. Gregory Co., Illinois Electric Construction Co., and others supplied the lighting material for the booths.

A WRONG IMPRESSION.

It is generally supposed that the demand for weather-proof wire is limited after December first, but the Electric Appliance Company report that their sales are increasing, and if anything, are larger than during the fall months.

MONOCYCLIC GENERATORS AT ST. LOUIS.

The second direct-coupled 800 K. W. monocyclic generator built by the General Electric Company has been started successfully in the St. Louis station. This machine and its brother which has been operating for some time in that station, are the largest generators of their kind, so large indeed that it was impossible to assemble them at the works before shipment. They are now operating successfully incandescent lamps, arc lights and motors in the city of St. Louis.

NEW ENGLAND NOTES.

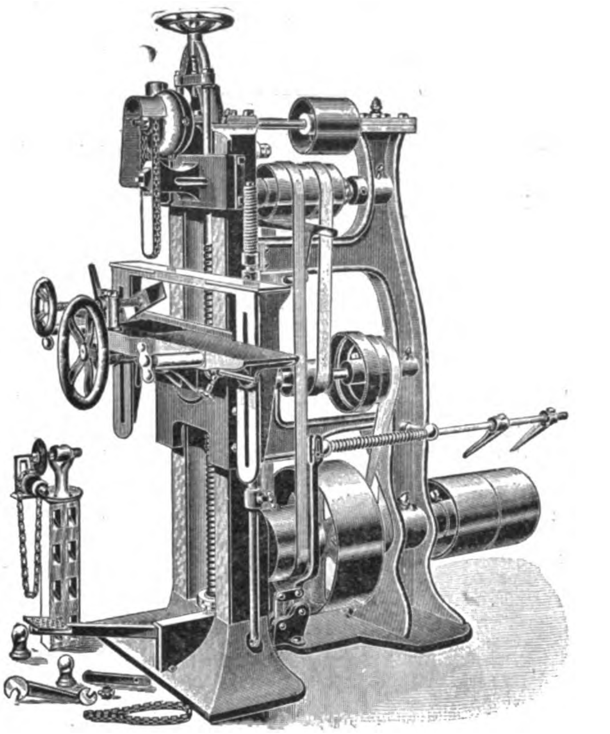
THE DIAMOND MACHINE Co., of Providence, R. I., has recently moved its department for the manufacture of leather covered wood polishing wheels into a new building, especially built and adapted to this purpose, thereby more than doubling the capacity for the manufacture of these goods. This move has been necessitated by the increased demand for wood wheels, recent orders having been booked for 500 wheels from one firm and 40 from another.

THE NEW BRITAIN MACHINE CO.'S CHAIN SAW MORTISER.

Perhaps one of the most important improvements in woodworking machinery introduced within the last decade is the chain saw mortiser, the patents for which are now controlled and the machine built by the New Britain Machine Co., of New Britain, Conn.

In this machine, one size of which is illustrated in the accompanying engraving, the cutting is performed by a steel chain, each link of which has a sharpened tooth so formed as to carry away its own chip, and is presented to the work a thousand times a minute, which illustrates the possibilities of the machine for rapid work. This chain, driven by a sprocket, travels over, and is guided by a chainbar having an anti-friction bearing at its lower end.

The table holding the work is fed automatically up towards the chain, the mortise, either "blind" or "through," is made at a single cut and the table rapidly descends to the starting point



New Britain Machine Co.'s Chain Saw Mortiser.

ready for another mortise so quickly as to almost limit the machine's output by the ability of the operator to supply it with work. Under ordinary circumstances, from 400 to 500 four panel doors can be put through in ten hours (each door having ten accurate, clean mortises,) and other work in proportion, depending on the size of mortise and hardness of stock.

The range of the No. 1 Standard Mortiser as at present constructed, is any mortise from $\frac{1}{16}$ to 1 inch in width, $1\frac{1}{4}$ to $3\frac{1}{2}$ inches in length, and up to $6\frac{1}{2}$ inches deep at a single cut, or up to 13 inches in depth by reversing the stock.

Our illustration represents the No. 2 Standard Mortiser which in size and capacity is a duplicate of No. 1 with the addition of a compound table, which is of great convenience in making very long mortises without unclamping the stock.

The New Britain Machine Co., also build the well-known Case engine which are admirably adapted to situations where space is limited. These engines are built in sizes from $2\frac{1}{2}$ to 25 H. P.

ADVERTISERS' HINTS.

Transformers of any voltage can be purchased of the General Electric Co.

The Standard Air-Brake Co. continues to discuss questions of practical importance to the street railway man.

Abendroth & Root Mfg. Co., are again advertising their improved water tube boilers. Their claims for these boilers have been substantiated under the most severe tests.

Roll Drop Commutator Bars is the topic of the Forest City Electric Co. who are pleased to furnish full particulars on request.

The Central Electric Co. remind their friends of their always up-to-date stock of incandescent light supplies. It includes every conceivable article for every style of lighting.

PHILADELPHIA NOTES.

Mr. Joseph Fritz, the electrician of the Francis Wilson Opera Co., playing in Philadelphia, shot himself through the heart on Jan. 8. He is said to have lost \$70,000 in speculation.

Camden, N. J.—It is claimed that \$400,000 has been improperly spent for lighting purposes by the City Council during the past eight years, in votes to the Camden Lighting & Heating Co.

The Falkenau Engineering Co., Ltd., have removed their offices to the suite 711 Reading Terminal Building and their stock room to the basement of the Reading Market. The excellent facilities of this building were recently described very fully in The Electrical Engineer, and the firm are now in good shape to handle any increase in their business, no matter how large.

CANADIAN NOTES.

Mr. R. Anderson, Ottawa, electrical engineer and contractor, reports having secured the following contracts: 700 light plant complete including street lights, for J. H. Francis, Pakenham, Ont.; 125 light plant, North American Graphite Co., Buckingham, P. Q.; 600 lights, J. D. McRae, Eganville, Ont., with 125 H. P. in electric motors; 150 lights at Union Station, Ottawa, for the Canadian Pacific Railway.

NEW YORK NOTES.

Speaking Tube Telephones.—The Metropolitan Telephone & Telegraph Co., 18 Cortlandt street, has issued a very interesting and instructive pamphlet on its "speaking tube telephones" for interior service of all kinds.

The Forest City Electric Company, of Cleveland, New York and Chicago, has recently issued a chart entitled "Divisions of Commutators" for the use of electrical engineers, designers of dynamos and repair men. This chart gives the degree and angle chord of bars in commutators of from 4 to 875 divisions. One of these charts will be mailed to those interested upon application to the nearest office. This data has been compiled by Mr. W. B. Cleveland, E. E., the Company's General Manager.

Eugene Munsell & Co., 218 Water Street, New York, with agencies in the principal cities, report an increased demand for solid sheet India and Amber mica, of which they make a specialty for electrical insulation. The Company import direct from the mines, and at all times carry the largest stock of mica to be found in this country. They have recently installed several new power presses, which gives them increased facilities for furnishing stamped solid sheet mica segments for all types of railway motors, and mica to any shape or pattern. Mr. Franklin Brooks, the junior member of the firm, is now making a tour around the world, and is spending considerable time at the mines in India, where the firm is largely interested.

NEW ENGLAND NOTES.

Mr. George E. Bliss has left the employ of the Malden Electric company and is now a member of the firm of Bliss & Pearson, dealers in electric supplies.

The Electric Railway Switch & Supply Co. has been formed at Saco, Me., to make switches and supplies, with \$100,000 capital stock, \$300 paid up. L. L. Davis, of Springfield, Mass., is president.

The Berlin Iron Bridge Co., of East Berlin, Conn., have just completed for the Windsor Co., of North Adams, Mass., a new fire-proof store house 70 ft. wide and 125 ft. long. The construction is composite, being iron and brick; the whole being fire-proof, no wood work being used. The floors are made of terra cotta.

The National India Rubber Co., of Bristol, R. I., have just closed a large contract for N. I. R. Cables; and their electrical department is exceedingly busy. They have completed extensive alterations and additions, and anticipate a good year's business. A new catalogue is in press and will be sent to their friends as soon as issued. They will also be glad to send a copy to anyone who will favor them with their address.

The Atlanta, Ga., Trolleys have to meet the novel competition of a "herdic" service at three cents. These little busses are already in use and seem to be popular.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE

Electrical Engineer.

Vol. XXI. JANUARY 22, 1896. No. 403.

ELECTRIC LIGHTING.

PHOTOGRAPHING AND SEEING IN DARKNESS.

BY

G. d'Infreville

THE publication in the last two issues of THE ELECTRICAL ENGINEER of cable dispatches from abroad announcing the fact that photographs had been obtained of objects screened from the sensitive plate by opaque bodies, has justly created a sensation the world over.

This announcement makes it incumbent upon me,—though I do so with some reluctance,—to publish my claims to a process for secretly photographing and seeing objects at night or in darkness without the use of the well-known flash light. This process has engaged my attention for several years, and one of the reasons I have kept it almost exclusively to myself and to a few trusted friends is, that I am still engaged in research in view of useful additions to it. On the other hand the complete description of the theory and of its practical application is out of the question, as it would at once destroy most of its value commercially.

I will state, however, so as to not mislead anyone, that the photographing or seeing in darkness does not give the same result as in daylight when obtained by the present well-known means. Some parts do not seem to appear as well, some others seem to be more visible; some features which were entirely invisible in daylight seem to be curiously disclosed even in some cases when covered by other substances. But the resulting effect is likely to be found interesting or useful.

I consider the seeing in darkness of particular importance, as photographing could not replace it as well or at all in many cases. For instance, it is advantageous to follow with the eye all the movements of a torpedo boat so as to take at the right time and without any delay proper and effective measures, such as the aiming and firing of guns, to repulse the attack. This process for seeing at night without being seen might, I think, be used to protect coasts and harbors against hostile fleet with particular advantages impossible to obtain with the use of the well-known search light as the latter indicates to the enemy that it is observed.

I think it will be possible by said new process for a man-of-war to secretly inspect its surroundings or a coast, or for a fleet to organize a constant and effective secret night watch against torpedo boats or carry on an effective night bombardment. It would, I think, help on land a comparatively small body of soldiers during a night attack to overcome a more numerous one not thus equipped. In short, in time of war the possession of said process would, I think, give superiority to the army or navy over an enemy not similarly provided. I think that policemen, night watchmen and detectives may with it watch or photograph interesting people or objects during darkness without being noticed.

These examples will suffice and need not be extended here as the field of applications may develop great variety and importance. Electricity has not a little to do with my process, but I would rather not tell to what extent, for the present.

I may conclude by reminding the reader that many animals can see in darkness; the cat and others of the feline family, the owl, the bat and even the horse, to some extent, are examples of it. Man has already outdone animals in other respects. Why could he not do it also in this one?

In reply to the editorial remark that while it may be of advantage to society it might also have its inconvenience, I would say that the process to some extent bears its own remedy with it, which can only be explained by disclosing the process itself. Are the telescope, opera glass or photographic camera classified among dangerous objects to-day? At any rate, can the progress of science be arrested and does it not result in the end to the greatest benefit of society?

THE DONSHEA METHOD OF CHARGING THE FIELDS OF LARGE CENTRAL STATION DYNAMOS.

THERE are three methods of exciting the fields of dynamos known as "Self-Exciting," "Bus Exciting" and "Separate Exciting." The advantages and disadvantages of these several methods are as follows:

In "Self-Exciting" the field terminals are connected to the brushes. The advantage of this method is that the field gradually dies away as the dynamo is slowed down, and when the dynamo is stopped, the field has entirely disappeared, thus avoiding danger of a sudden discharge of the field which would probably pierce the insulation of the field winding or make a short circuit through the armature.

The disadvantages of this method are: first, the slowness with which the dynamo builds up its own field, the dynamo frequently running at full speed for a considerable length of time before it develops E. M. F. sufficient to be connected into the system; second, the possibility that the field may build up reversed. This may be caused by a sudden discharge of the field, by a short circuit, or even by proximity to another dynamo.

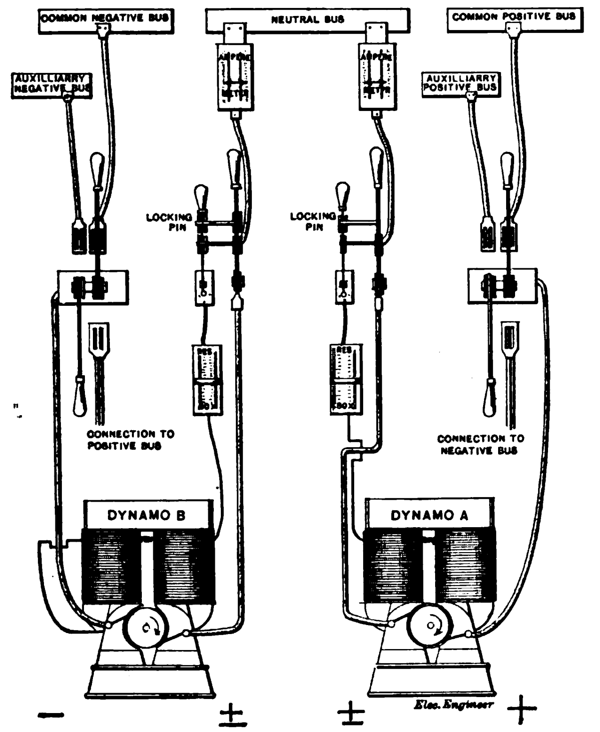
In "Bus Exciting" the fields are connected to the station mains or busses. The advantages of this method are: first, that the field is instantly made and the dynamo can be connected into the system as soon as it is up to speed; second, the polarity of the field is always the same, and hence cannot come up reversed. The disadvantage of this method is that the field is on although the dynamo may be shut down, and it is necessary to discharge it through a bank of lamps or other resistance by means of a field break switch. This method of discharge, although safe, might cause trouble were the bank of lamps disconnected or otherwise out of order.

In "Separate Exciting" the field circuit of each dynamo, or of all the dynamos, is connected to a special dynamo or other current producing device. This method possesses the same advantages and disadvantages as the "Bus Exciting" method does. It has the additional disadvan-

tage that the exciting dynamo or battery is small, and, therefore, weak and unreliable. An accident to it would cause the loss of as many dynamos as were being charged from it. To obviate the difficulties above enumerated with the three systems of field excitation, Mr. W. I. Donshea, of the New York Edison Company, has devised a method which is in use in the stations of that Company and has also been introduced in a number of Edison stations in other large cities.

In the Donshea method, one side of the field coil winding is connected to one of the brushes, while the other side of the winding is brought through the regulating resistance box to the blade of the field switch. As shown in the accompanying illustration, this blade is pivoted on the same axis as the blade of the main dynamo switch on the regulating switchboard, but not connected with it electrically.

When the blade of the field switch above referred to is closed it makes contact with clips connected to the neutral bus. The field circuit is then made from the neutral bus,



THE DONSHEA METHOD OF CHARGING DYNAMO FIELDS.

through the field switch, through the regulating resistance box, through the field coils and to the brush which is connected through a switch with the positive or negative bus, and the field is thus bus excited. When the dynamo is up to pressure, as indicated by the dynamo galvanometer, the main dynamo switch is closed. On the blade of this switch are mounted clips which engage into the blade of the field break switch and a pin or latch which is operated by a spring drops into a hole or slot on the blade of the field switch and securely locks the two blades together. Thus when the blade of the main dynamo switch is opened it brings the blade of the field switch with it, the two remaining in electrical connection together. The field is thus self excited. The engine is then slowed down, the field gradually dying out.

When the dynamo is wanted again, the pin or latch which locks the blade of the field switch to the blade of the main dynamo switch is withdrawn and the field switch blade is brought up in contact with the clips connecting to the neutral bus. This instantly charges the field and full field is had by the time the engine is up to speed. By means of this method the main circuit and the field are opened at the same time and the discharge of the field takes care of itself in the slowing down of the machine, there being no break in the field at any time.

A further advantage of this method of exciting the field is that as the field is connected on one side to the opposite pole to the neutral (that is the positive or the negative) it is charged from the common or the auxiliary bus, depending on which bus the dynamo is connected to. When running on the auxiliary bus the higher pressure maintained there gives a greater working margin in the regulating resistance box than is possible when the fields are charged from the common bus. A further advantage of this method is that it greatly simplifies the apparatus used for throwing over the dynamos from one side of the system to the other in the three-wire system. It is usual to employ a throw-over head board switch on the dynamo from which three cables are led to the switch-board, being connected to the positive, negative and neutral buses, respectively. In the Donshea method no head board change-over switch is required and but two cables from the dynamo to the switch-boards need be run. One of these cables would be the permanent connection to the neutral bus through switch and ammeter and the other would be connected to a change-over switch connected to both the positive and the negative busses.

This system of field charging can be readily applied to existing switchboard construction by the simple addition of a special Donshea switch directly attached to the blade of the neutral dynamo switch as ordinarily constructed.

AMERICAN APPARATUS IN THE MUNICIPAL LIGHTING PLANT, ODESSA, SOUTHERN RUSSIA.

THE electric lighting station at Odessa, installed in 1888, has recently received an interesting addition in the shape of three American alternators with full equipment, in the construction and installation of which special and peculiar requirements had to be met. The old plant consisted of two Ganz low frequency alternators. In ordering the new machines of higher frequency and higher potential, it was necessary that the current furnished should not only supply the Ganz transformers but run in conjunction with the old generators, and as the municipality would grant no further space for a station, the installation had to be crowded into very restricted quarters.

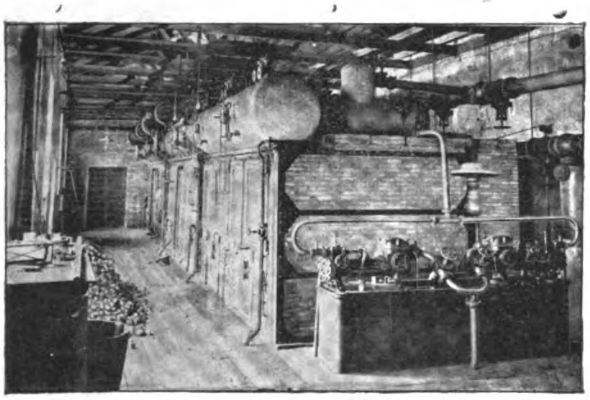
The original plant was erected to light the Municipal Theatre at Odessa, one of the handsomest buildings in the South of Russia, and comprises two 80 K. W. Ganz alternators, directly coupled to non-condensing engines. The voltage of the primary circuit is 1850 volts and that of the secondary 60 volts, the distance between the station and the theatre being about 2,700 metres.

The success of the illumination of the theatre was such that electricity was also supplied to other neighboring buildings. The capacity of the station soon became severely taxed, and in June, 1893, the municipality at Odessa decided to increase the existing plant to meet the constantly increasing demands. After considerable competition the contract for the addition to the station and for the exploitation of the new installation for 15 years, was granted to Mr. J. Margulis, a well known engineer of Southern Russia. He decided to use the Thomson-Houston system of lighting as it seemed the better to respond to the local requirements than any of the European systems which were offered.

The new steam generating plant consists of two Collet water tube boilers, built in Paris, with a capacity of 2,250 kilog. of water per hour at a pressure of 12 kilogs. per square centimetre. The boilers are set in one battery and are fed by two Worthington pumps. Attached to each of these pumps is a special reservoir in which the water flows from the condenser. The piping is so connected with that of the former installation that all the boilers work in parallel.

The steam engines are vertical tandem compound condensing machines of 175 H. P. each, from the works of Franco Tosi of Legnano. They run at 260 R. P. M. and are furnished with governors which regulate the speed so that the variation is only $2\frac{1}{2}$ per cent. between full load

and no load, a condition necessary to obtain the satisfactory operation of alternators in parallel. Each engine is furnished with an independent jet condenser driven from a pulley on the engine shaft. The condensers are placed beneath the engine room. In order to cool the water in these condensers a Chaligny aero-refrigerator has been installed and to avoid the employment of supplementary pumps to raise the water discharged from the condensers the apparatus has been placed as low as possible, while the air pumps have been specially constructed to throw the water to a height of 3½ metres. A small steam engine is employed to drive a fan forcing a current of air through the tubes over which the hot water flows. By this arrangement the dimensions



BOILER ROOM, ODESSA ELECTRIC LIGHT STATION.

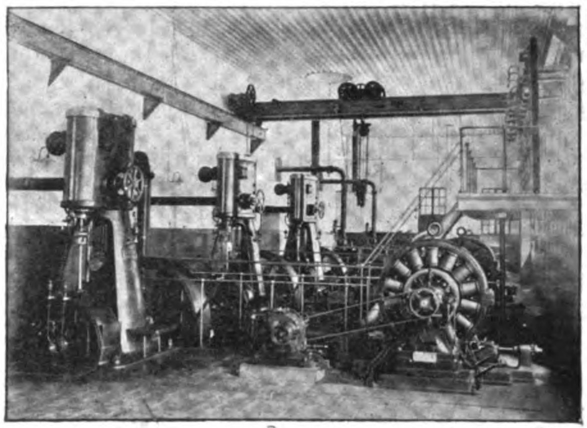
of the refrigerator have been greatly reduced and a vacuum of from 65 to 68 centimetres of mercury can readily be maintained with an expenditure of water not greater than that necessary to feed the boilers under ordinary conditions.

The three alternators are Thomson-Houston 120 kilowatt, 14 pole 1,070 revolution machines of standard frequency, giving 2,000 volts at no load and compounded for 2,200 volts at full load. They are driven by perforated leather belts from the engines and as the station building was already constructed when they were installed, the greatest distance allowable between shaft centres was 4.50 metres.

The exciters are of the Volta type, built in Paris by the firm of Postel-Vinay. They are compound wound and are driven from pulleys fixed to the alternator shaft. Each exciter has a capacity of 3,300 watts at 125 volts and suffices to excite all three alternators simultaneously.

The switchboard is built up of marbleized slate panels. The switches for the primary circuits are mounted on separate slate bases and have a further insulation of ebonite. The exciter switches are three pole and the main switch four pole, two of the poles being used for equalizer connections. The rheostats in the exciting circuits are arranged for connection in groups in order to vary the potential of all the dynamos simultaneously and thus avoid any unequal distribution of load. Each exciter is provided with an ampere meter and a fuse; each alternator with an ampere meter and station transformer with its voltmeter. Each primary conductor is provided with a fusible cut-out at its point of connection with the main switch. The single pole switches for the alternator and exciter circuits are so arranged that the circuits are broken through incandescent lamps, and these lamps are also used as pilot lamps for the individual machines. The secondary circuits of the station transformers are so arranged that by closing two small single pole switches the phase lamps for the machines are brought into circuit. By means of special grouping of the reactive coils and a special commutator, no excessive rush of current is produced when the alternators are thrown in parallel, even when the phases are in opposition. A momentary fluctuation of the lights is produced on account of short circuiting the machines through the reactive coils, and it is, therefore, advisable to use the phase lamps and to close the main switch the instant the machines are in phase. As a speed variation of from 2 per cent. to 2½ per cent. between full load and no load exists in the engines, the pulsations in the lamps vary between 150 and 180 per minute. In order to diminish these pulsations, as much as possible, before throwing the machines in parallel, one or other of the following means is employed. The first consists in closing the valve on the engine driving the new alternator until this revolves in synchronism with the others under full load, and at this moment the switch is closed and the valve opened. The second method consists of closing the valve until the speed of the engine falls below that of those already in service; the valve can then be opened rapidly and the switch on the new alternator closed the moment the machines come exactly into phase.

According to the specifications of the municipal authorities, the three 120 K. W. alternators must work in parallel, and be so arranged that the Ganz circuits with transformers at 40 periods at 1,850 volts can be supplied by the Thomson-Houston alternators at 125 periods per second at a potential of 2,000 to 2,200 volts. That is to say, that at any given moment the Ganz machines can act as reserve for the Thomson-Houston group and the Thomson-Houston machines can act as reserve for the Ganz dynamos. In order to do this, a compensator is employed to bring the potential down to that of the Ganz circuit. The compensator is furnished with a number of terminals in order that the potential may be varied, if the load on the Ganz circuit varies in proportion to that on the other circuits. The speci-



ENGINE AND DYNAMO ROOM, ODESSA, RUSSIA, ELECTRIC LIGHT STATION.

fications stipulated that there should always be a dynamo in reserve, and the two Ganz machines are used for this purpose. Another circuit is furnished with Ganz transformers, but takes its current from the Thomson-Houston compensator. In case of accident, the 40 period circuit can be taken off the Thomson-Houston machine and connected to the Ganz dynamo and the result is that the same flexibility is obtained in the system as if all the dynamos were of the same frequency and all operated in parallel. The experiments carried out by the municipal engineers before the city accepted the plant proved that with the necessary precautions the American alternators operate in parallel as advantageously and as readily as direct current machines. Excitation of the individual machines can be varied; the line potential is that which each machine would have if it ran individually under similar conditions; the change from condensing to non-condensing or vice versa can be effected upon any engine when its dynamo is running in parallel with the others, without difficulty. Any number of alternators can be thrown in parallel with or without load as easily as direct current machines under similar conditions.

The plant in question is now considered as one of the

most satisfactory operated in Europe, and it is more than gratifying to find that in spite of all the deserved and admissible claims made for European electrical machinery, American apparatus seems to be that which at this present moment is meeting with the greatest success in Europe whether for lighting or for railway purposes.

THE POLLAK CURRENT RECTIFIER FOR CHARGING STORAGE BATTERIES FROM ALTERNATING CURRENTS.

ONE of the decided novelties exhibited at the World's Fair in Chicago was the current rectifier of Mr. Ch. Pollak, of Frankfort on the Main, Germany. This apparatus, which was illustrated and described in THE ELECTRICAL ENGINEER of Sept. 13, 1893, is intended to convert alternating into continuous currents for charging storage batteries. Its construction is such that of the pulsating current obtained by rectifying the alternating current, only such portion is used as is equal to or higher than that of the battery, all other portions of the current impulse being rejected for obvious reasons.

In a recent number of the *Consular Reports*, U. S. Consul Frank H. Mason, at Frankfort, Germany, draws attention to the successful operation of the Pollak rectifier and gives the results of some of its work in the Pollak Accumulator Works in Frankfort. Electricity is supplied at Frankfort from the municipal central station at 7¼ pfennigs (a little more than 1¾ cents) per unit, in the form of single-phase alternating current of 3,000 volts. At the accumulator works, this current is reduced by transformers to 65 volts and then rectified and fed to the storage batteries.

Four of these rectifiers, each for 350 amperes, have been in continuous service day and night at the works of the company in Frankfort for more than a year, with such complete success that the system may be fairly claimed to have passed the experimental stage. Their efficiency is stated to be 96 per cent.—that is, the alternating currents are converted into direct ones with a net loss—including

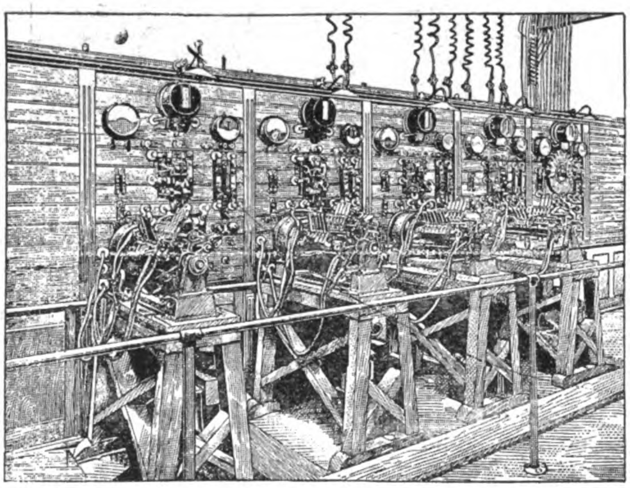


FIG. 1.—POLLAK CURRENT RECTIFIERS.

the slight reaction of about 2 per cent. on the transformer—of only 4 per cent.

The current from the rectifiers also operates arc and incandescent lamps, runs continuous-current motors of all sizes down to the smallest, and is used for charging storage batteries, which is the chief function of the Frankfort company. The rectifier and its accessories are exceedingly compact, the whole installation, including seven transformers, occupying only 25 square yards of space, within which compass the apparatus and its capacity might easily be doubled should occasion require. The rectifiers are small, require no other foundation than wooden trestles resting on a solid factory floor, and demand no more oversight than an ordinary dynamo. Mr. Mason states that from the testimony of the inventor and the numerous experts who have visited Frankfort specially to examine the system, the current supplied by the new rectifier is for

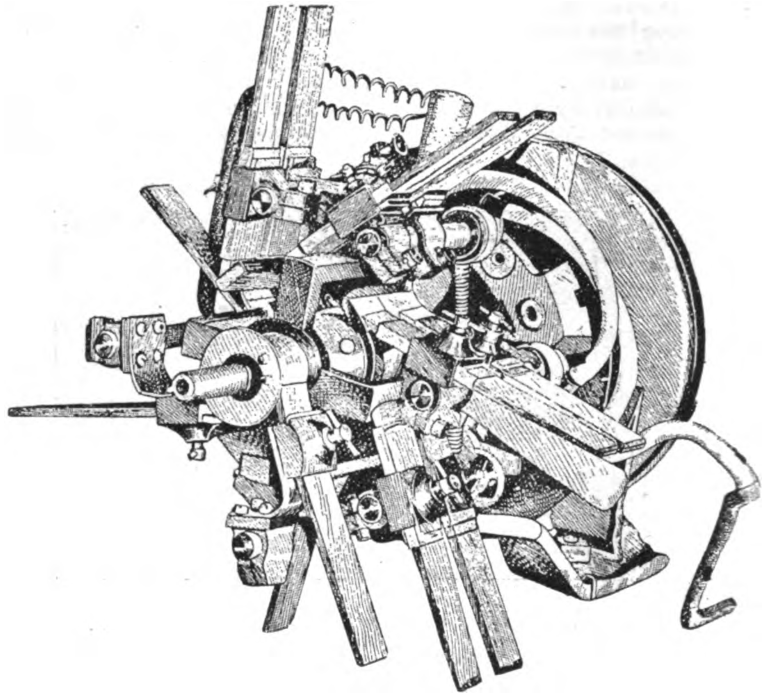

FIG. 2.—POLLAK CURRENT RECTIFIER.

all practical purposes identical in value and effects with the continuous currents hitherto produced in the ordinary manner. We may add that the apparatus has been recently patented in this country.

THE ALLEGED "OUTAGES" IN CINCINNATI.

Superintendent Beggs, of the Cincinnati Edison Co, appeared lately in response to the call of the local Board of Administration to show cause why the city should not settle the outages on the basis of the Police Department Reports, recently mentioned in these columns, and he evidently succeeded in doing so. He was armed with reports of the city inspectors placed in the central lighting station last month, and set out to show that the system of reporting lights was defective. A time elapses between the moment when the officers discovers the light out and the time it gets through two reports and to the central lighting station. Again, officers report a light out just before they change watch, and it stands as "out all night," even if relighted a short time afterward. Reports were received last month from places where no lights are located. The point was also raised that if the time for lighting the city in the evening is 5 o'clock and the lights were not turned on until 5:55, the contract did not provide that as an outage and it should be deducted.

The outcome was that the board decided to settle on the Edison figures, and to notify Superintendent of Police Deitsch that the police do not report to the central lighting station all of the outages reported to the Board of Administration.

AN EDISON STATION FOR LOS ANGELES.

The Los Angeles Edison Light and Power Company is the name of a new corporation that has been formed for carrying on a general electric lighting and power supplying business. The head of the company is Charles R. Lloyd of San Francisco. It is understood that the new company proposes to commence inside of sixty days putting in its plant. The promoters of the new enterprise say that the plant to be put in will be the most modern in its equipment of any in the United States. It is intended to spend $500,000. The wires will all be laid underground in the business portion of the city. Several Los Angeles men are interested in the enterprise. The plant is to have a capacity for 30,000 incandescent lamps and 500 arcs.

A GOOD CROSS-EXAMINER.

A short time ago a large factory, fitted with the most modern appliances, including electric light, caught fire, and despite the most strenuous efforts of the fire brigade, was almost demolished.

The following morning a newly-appointed member of the force was dispatched to the spot, with a view of ascertaining how the fire originated. After closely interrogating the manager of the factory, he asked to see the man who was responsible for the electric light.

The manager stated that the electric switches were under his sole control.

"Then you are the man that lights up the electric affair?" said the policeman.

Manager—That is so.

Policeman (bubbling over with excitement)—Now, be careful how you answer my next question, 'cos if it ain't satisfactory, it will be took as evidence against ye. When you lighted the electric light last night, where did you throw the match?—*Pearson's Weekly.*

ELECTRIC LIGHTING SALE ON STATEN ISLAND.

The sale at auction of the property of the Electric Power Company of Staten Island has been fixed for Jan. 29. This company was practically owned by Erastus Wiman. At the time of his failure it passed into the hands of Albert B. Boardman, as receiver, and he has since operated the plant. The company has contracts for lighting New-Brighton and Edgewater, and there is expected to be competition for the property between the unsecured creditors, represented by Austin B. Fletcher, and the Thomas syndicate, which owns nearly all of the bonds. The property does not include the new plant at Livingston.

GEDNEY CHANNEL LIGHTS CRUSHED BY ICE.

Large quantities of ice were taken to sea by Sandy Hook last week by the ebb tide. The ice came mostly out of the Shrewsbury River and from the Jersey shore. Every electric light on the buoys marking Gedney Channel across the bar was extinguished by the ice, and only the red light on the buoy at the Southwest Spit was left in working order. The Lighthouse Department was notified and new lamps were supplied.

THE PADUCAH, KY., MUNICIPAL PLANT IN BAD SHAPE.

Mr. C. C. Chapman, who has been employed as superintendent of the Municipal Electric Light Plant at Paducah, Ky., has resigned pursuant to a request from the council. For some time past the electric light system has been in bad shape. A committee was appointed and decided that the defective service was due to the incompetency of the superintendent.

MORE MONEY NEEDED FOR THE ALAMEDA MUNICIPAL PLANT.

At the last meeting of the Alameda, Cal., Municipal Trustees plans and specifications were read for the installation of additional electrical machinery to the city's plant, involving an outlay of some $15,000. It will necessitate the erection of a new building, the placing of a new engine and boilers and of a new dynamo of a capacity of 4,000 incandescent lights. Proposals will be invited at once for the work. The money to pay for the same was raised by increasing the taxation from $1 on each $100 of assessed value to $1.22. At the time the tax rate was fixed it was not stated what the increase was for, as it would undoubtedly have raised a storm that could not have been withstood; but as the affair blew over and feeling subsided the new improvements were proceeded with. The electric works absorbed $27,000 of the public funds last year, when a great deal of the plant was renewed, at least $19,000 of it going for construction. But it is claimed this further outlay is necessary to make the incandescent branch profitable. It is the purpose to have a capacity of at least 4,000 incandescent lights for the plant.

A COSTLY PISTON ROD FOR A CENTRAL STATION.

A special despatch from Burlington, Ia., of recent date, says: A broken piston rod in the electric light works caused the shutting off of all street and residence lights in this city. A new rod was ordered from Sioux City, and to have it here in time for to-night's lighting the managers of the electric plant chartered a special train from Sioux City, Iowa, to Cedar Falls, over the Northwestern to make connection which would bring it here on time. It makes the rod the most costly one on record.

INDIANAPOLIS, IND.—An ordinance has been passed giving the Board of Public Safety power to make rules in regard to electric wiring and to confer police powers on an electrical inspector, paid for by the insurance companies.

NEWS AND NOTES.

THE ANNUAL ELECTRICAL AWARDS OF THE ACADEMIE DES SCIENCES.

The last number of the *Comptes Rendus* is taken up with announcements of the 1895 prizes awarded for scientific, mathematical, and engineering work. We append a list of the prizes awarded for electrical researches:—The MONTYON PRIZE of 700 fr. has been awarded to M. Galliot for his successful introductin of an electrical towing arrangement for a distance of 6 kilometres on the Burgundy Canal. Some two years ago M. Galliot decided to electrically utilize the head obtainable between the feed-water reservoir and the third lock on either side of it, and since then all barges have been towed up and down by a motor-barge deriving its current from a trolley wire running along the banks of the canal, and connected to turbine-driven dynamos. The water necessary for the operation of the locks is not interfered with, the turbines being fed by the large volume of water necessary to make good the losses by infiltration.—The LA CAZE PRIZE of 10,000 fr. was awarded to M. Edmond Bouty, Professor at the Paris Faculty of Sciences. M. Bouty discovered a curious phenomenon connected with electro plating, to which he gave the name of "electrostriction." For instance, if a thermometer bulb be copper-plated an appreciable permanent displacement of zero is found to take place, corresponding to a pressure of several atmospheres. M. Bouty's explanation is, that this phenomenon of expansion or contraction is due solely to abnormal temperature, caused by the Peltier effect. Recently M. Bouty has investigated the influence of the layer of air left between the metal plates of a condenser and the solid dielectric, and, finding it considerable, M. Bouty now silvers the faces of his mica condenser sheets.—Another LA CAZE PRIZE was awarded to M. H. Le Chatelier, well known for his work on the electric pyrometer. By the aid of this instrument he has, amongst other things, observed that at 580° C. quartz suddenly expands, though its molecular composition is not modified; the process is reversible.—As already announced, the LECONTE PRIZE of 50,000 fr. was awarded to Lord Rayleigh and Prof. Ramsay for their discovery of argon.—The GASTON PLANTÉ PRIZE, a biennial one of 3,000 fr. was awarded to MM. J. and P. Curie for their work in "piezoelectricity."—The KASTNER-BOURSAULT PRIZE of 2,000 fr. was awarded to M. Baudot, the inventor of the well-known multiple-writing telegraph much used in France.

ELECTRICITY ON THE CANALS.

There has just been issued an important supplemental report to the annual report of the Superintendent of Public Works. It is written by Charles R. Barnes, State electrician, of Rochester, and treats of the proposed introduction of electricity upon the canals. Commenting upon the report the Superintendent says: "I am very sanguine that electrical canal-boat propulsion is not only possible, but also that the devices which have been already tested and are being constantly improved will result in a perfect system within the time required for the general improvement of the canals now inaugurated. The test seems to be satisfactory and to indicate that as soon as the details of the system are so worked out as to meet every contingency of canal-boat traction, it will become a cheap and favorite one with boat owners and forwarders; and that the cost of traction will be largely reduced and the speed greatly increased."

The report of Mr. Barnes describes the Lamb electric-towing system, which consists, essentially, of a stationary cable-way, supported by a line of poles along the canal bank, and electric motor carriages travelling thereon and towing a boat or boats attached thereto. It is familiar to readers of THE ELECTRICAL ENGINEER.

EDUCATIONAL.

ELECTRICAL ENGINEERING AT MAINE STATE COLLEGE.

THE Maine State College has recently installed as an addition to the electrical laboratory and for the practical purpose of lighting the grounds and buildings a 40 horse-power multipolar generator built by the Eddy Electric Mfg. Co., Windsor, Ct.; also a 20 horse-power bipolar dynamo manufactured by the Belknap Motor Co., of Portland, Me. These are belted to a jack-shaft, run by a 60 H. P. Hamilton-Corliss engine. The boiler is the Heine water tube type of 85 H. P. The plant also includes 58 Bradbury-Stone 800 ampere-hour storage cells, which take care of the light load after eleven o'clock.

The college, located at Orono, Me., ranks well among New England's technical institutions.

Power Transmission.

ELECTRICAL POWER FRANCHISE FOR BUFFALO.

BY I. C. WOOD.

THE Niagara Falls Power Company having, on January 14th, formally accepted the grant approved by Mayor Jewett on December 16th, 1895, the elongated query as to whether or not the power generated by the Falls of Niagara would ever run the cars, light the streets and turn the wheels of industry in Buffalo, may be now answered affirmatively. For we take it as assured that at least the Buffalo Railway and the Buffalo General Electric Company will find it convenient to use, and the Power company find it profitable to furnish this power.

The terms of the grant were practically dictated by Attorney Rankine of the Power company, hence are quite favorable to that corporation. Nevertheless, the interests of the city, though at times subordinated to the desire of some to have power at any price, were intelligently provided for by the joint committee which is responsible for the city's approval of the charter as it now stands.

The grant covers a term of 66 years from date of acceptance; it requires the furnishing of 10,000 H. P. on or before June 17, 1897, and an additional 10,000 H. P. per year for four years thereafter.

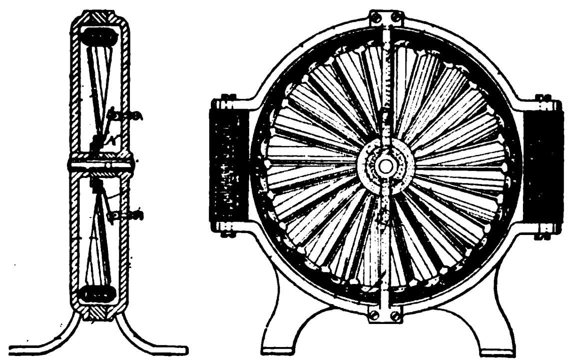
Commencing with the year ending January 15th, 1903, the Niagara Power company must pay, at the end of each year, 2½ per cent. per annum of its "gross receipts from all electricity sold or furnished for lighting, heating or power purposes to any person, company or corporation for use or to be used in said city [Buffalo] regardless of whether such electricity shall be furnished or delivered under this grant." At the end of the twelfth year (1914) of such payment, i. e. eighteen years after acceptance of the grant, there is to be a readjustment of the percentage of earnings paid to the city which adjustment is "to be made by three arbitrators, one to be appointed by the company, one by the Mayor of said city, and the two so elected to appoint a third, and such arbitrators by a majority vote shall have full power to increase or decrease the percentage to be paid or otherwise regulate or adjust the same as to them shall seem just and equitable."

In the controversy over the terms of the franchise, it being admitted by Mr. Rankine that the power would be distributed in Buffalo by a sub-company, the following question arose, viz:—Might not the power company sell its product to this sub-company at a nominal price, so as to reduce its (the power company's) own gross earnings from Buffalo business, and so scale down the amount upon which it would be required to pay to the city on the 2½ per cent. basis? The inference was that though ostensibly losing money on its contract with the sub-company, the profits of such sub-company would eventually reach the treasury of the principal company. To prevent such methods, a clause was inserted in the grant permitting one assignment of the franchise, after six months from its acceptance, on condition that the assignee company agree to pay the same as would be required of the principal company. This, of course, meets the point, except that it is still possible to sell *all* the power to one, two, or three large consumers, at a nominal price, and, by being interested in these concerns, the company could take its profits from them and so reduce its 2½ per cent. tax. But the idea of such methods being pursued by Mr. Adams and his associates in the power company is altogether too ridiculous.

No price has been set for power delivered in Buffalo. This point was the centre of the franchise fight, and the company won. It early took the position that the actual cost of transmission was not exactly known, and that Buffalo must rely upon the business proposition that the company must, someway or other, reduce the price to where they could successfully compete with the present cost of power, minus cost of changing to electrical operation. The grant provides against discrimination or favoritism after a price has once been made.

DIEHL'S NOVEL FAN MOTOR.

MR. PHILIP DIEHL, the well-known inventor, has added many ingenious devices to the list of electrical apparatus, and one of the latest is a novel fan motor, the construction of which is clearly shown in the accompanying engravings. It will be noted that the fan-



NEW DIEHL FAN MOTOR.

blades are arranged inside of a ring-armature, with the field-magnet located outside of the armature. The commutator is placed on the hub of the fan, and the fan-blades are utilized as conductors between the commutator-sections and the armature. In thus utilizing the fan-blades as conductors they are insulated from each other and the armature-ring is wound in sections corresponding in number to the number of the fan-blades, the latter being of course electrically connected with the commutator and armature sections.

A POLYPHASE TRANSMISSION PLANT FOR GUATEMALA.

Messrs. Siemens and Halske, of Berlin, have in course of construction a long-distance transmission plant which is to be operated by the "Empresa Eléctrica de Guatemala," and which is intended to carry electric energy for light and power purposes to the town of Guatemala from a waterfall 22¼ miles distant. The system of transmission is the three-phase, at a pressure of 10,000 volts, with step-up and step-down transformers at either end of the line. Power is to be derived from the outlet of a lake giving 2,000 litres per second, with a fall of 87 metres. At present, therefore, some 1,300 H. P. is available. But it is contemplated in the near future to carry out works permitting the water of the lake to be accumulated during the daytime; this will bring the available power to 5,000 or 6,000 H. P. The plant now in view consists of a set of two horizontal Nagel and Kaemp turbines of 520 effective horse-power each, running at 200 revolutions per minute. Each turbine is coupled direct to a Siemens and Halske three-phase alternator capable of generating 425 kilowatts at a pressure of 850 volts. The current is transformed by a set of four transformers from the pressure of 850 to 10,000 volts, then transmitted to the town by a three-conductor aerial line having an aggregate section of 105 sq. mm., the maximum loss in the line amounting to 10 per cent. On reaching the town the pressure is lowered again by another set of four transformers from 9,000 to 1,000 volts, the current being then distributed to the supply network of the town. The distributing conductors are overhead, carried on iron poles.

MORE ELECTRICITY FOR MOLINE.

The Moline Water Power Company has awarded the Trump Manufacturing Company of Springfield, Ohio, the contract for an important extension of the company's capacity for generating electric power by means of water wheels. The new turbines, twelve in number, with the present steam power will produce a total of 6,000 horse-power. The whole improvement will cost $140,000.

MR. W. S. KELLY, a well known electrical engineer of Boston, is pushing a scheme for generating electric power at Howe's Pond in Readsboro, Vt., and transmitting the current to North Adams and other points.

ELECTRIC TRANSPORTATION.

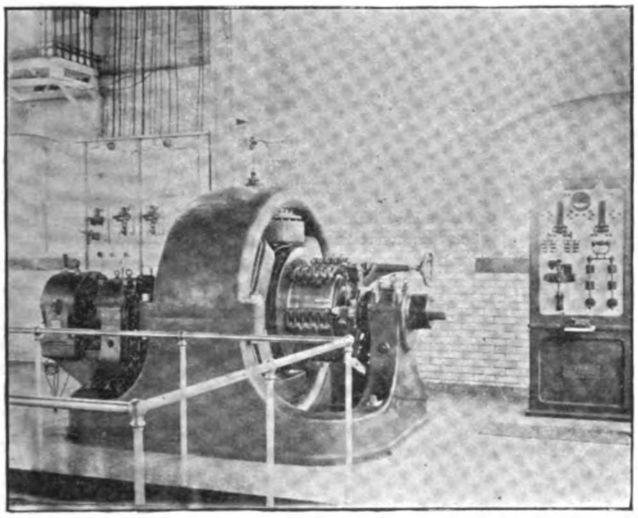
POWER EQUIPMENT OF THE NIAGARA FALLS RAILWAYS.

BY ORRIN E. DUNLAP.

THE Buffalo and Niagara Falls Electric Railway, the various lines of the Niagara Falls and Suspension Bridge Railway and the Whirlpool and Northern Electric Railway are now enjoying a power service from the central station of the Niagara Falls Power Company. In reducing the voltage and changing the current from alternating to direct, a rotary and a pair of static transformers are used, views of which are given in the accompanying engravings. The rotary transformer is placed in the northeast corner on the main floor of the power house, while the static transformers are located below the main floor. These transformers were furnished by the Westinghouse Company.

It is well known that if the armature of any direct current dynamo be tapped at points which are electrically 180 degrees apart, an alternating current can be drawn therefrom. If now the dynamo be run as a motor from the direct current end an alternating current can be drawn from collector rings tapped on at the points above mentioned; and, vice versa, if the dynamo be run as a synchronous alternating current motor a direct current can be taken from the commutators. This last is the principle on which is constructed the 500 H. P. rotary transformer supplying the electric railways around Niagara Falls.

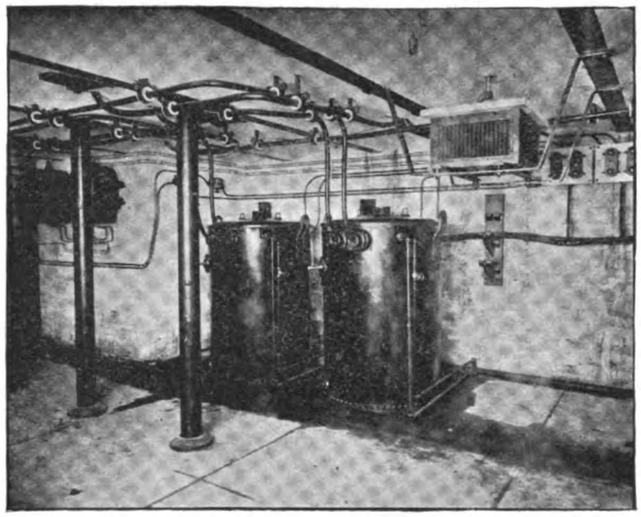
The source of power is the great 5,000 H. P. dynamos.



ROTARY TRANSFORMERS IN POWER HOUSE OF NIAGARA FALLS RAILWAY SYSTEM.

The function of the rotary transformer and its accompanying static transformers is to change the 2,000 volt alternating current into a 575 volt direct current so as to adapt it for use on a street railway circuit equipped with standard street railway apparatus. The current is brought from the main bus bars at a potential of about 2,250 volts by four 600,000 C. M. cables. This size of cable gives ample room for the expansion of the system. Four cables are necessary, as the current is distributed on a quarter phase system, with two cables for each phase.

These cables are connected to the middle points of two double-pole, double-throw switches. Throwing the switches up throws the current into two auxiliary static transformers, the secondaries of which are connected to a quarter-phase starting motor. The armature of this starting motor is on the same shaft as the rotary transformer armature. The method of starting is to first throw both switches up; this throws the current into the starting motor and the shaft starts and is brought up to speed. Now the field circuit of the main armature is closed and voltage allowed to build up. The phase relation of the armature is determined by synchronizing lamps. These synchronizing lamps are two in number and placed in series with the secondaries of two 2,000 to 100 volts converters, the primaries of which are attached, one to the main dynamo circuit and one to the 2,000 volt side of the static



STATIC CONVERTERS IN POWER HOUSE OF NIAGARA FALLS RAILWAY SYSTEM.

transformers feeding the rotary. When the armature is near synchronism, these lights will slowly grow bright and then dim. By watching these lamps one can choose the proper moment to throw the switches down. This done, the dynamo current passing through the two static transformers is reduced in voltage by them from 2,250 to about 440, and the current increased in the same ratio. The current at this reduced voltage then passes into the alternating current end of the revolving armature, running it as a synchronous motor. In its passage through the revolving armature the voltage is increased in the ratio of 7 to 10, which makes the final direct current voltage about 600, which is fed to the railway circuits.

THE SUBMARINE BOAT "LE GOUBET."[1]

THE most recent addition to electrically propelled boats is the "Le Goubet," just finished in Paris, which embodies a number of novel features, largely the result of experience gained with a smaller boat of the same name, built several years ago. The present "Le Goubet," which is illustrated in the accompanying engraving, Fig. 1, mounted on a truck passing through the streets of Paris, measures 8 metres in length, with a maximum beam of 1.75 metres. Its weight is about 10 tons, and it is built in three sections, which are bolted together, with a false keel, weighing 1,200 kilogrammes.

Fig. 2 shows a view of the interior of the boat looking toward the bow. The operator has before him the handles *a a* opening to the sea water the discharge of the pumps, the cocks of which are shown at *b b*; these pumps, according to the position of the valves the hand wheels of which are shown in *c c*, expel the water which serves as ballast or the vitiated air, which owing to the increased density of the carbonic acid, sinks to the bottom of the boat.

Behind the operator's head at *d* is the "postal" apparatus, by means of which a small hermetically sealed case

1. From *La Nature*.

containing despatches is put into communication with a vertical chimney communicating with the sea water. The object deposited in the postal box rises to the top of the water owing to its small specific gravity. The cone shaped bow also contains the steel tubes which hold the compressed air used as a reserve for breathing purposes.

Looking toward the stern of the boat on the interior the view shown in Fig. 3 is presented. Here is seen the electric motor, operated by batteries which will be ranged on each side of the boat. The machine above which is shown the hand wheel which controls the movements of the screw hides the regulating gear wheels. On the walls of the prow are shown the torpedo discharging apparatus. Just below the lookout tower is placed a lever, which by means of a quarter turn detaches the false keel which acts

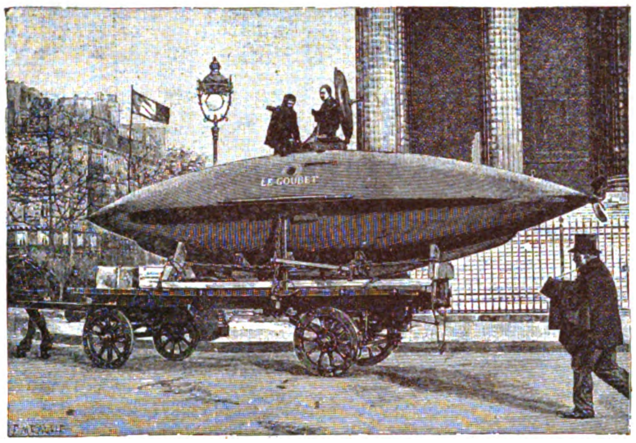


Fig. 1.—The Submarine Boat "Le Goubet."

as a safety ballast, so that the boat may immediately arise to the surface in an emergency. Ordinarily the boat will float at the surface, the small lookout cap alone being visible above the level of the sea, but upon entering the dangerous zone a little water introduced into the bottom

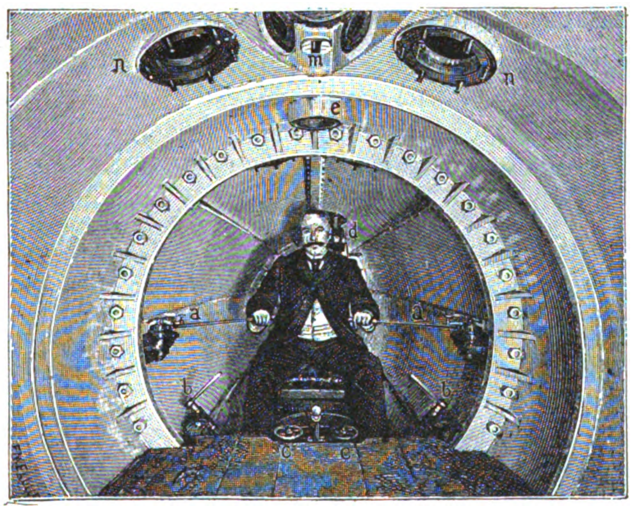

Fig. 2.—"Le Goubet."—Looking Towards the Bow.

of the boat sinks it to the proper depth, about four or five metres, and ten metres if necessary.

The dead lights are but a small help for the purpose of making observations, but in order to give those inside accurate information as to their location, a vertical tube consisting of a system of telescopes and reflecting prisms is pushed up from the top of the boat, rising above the level of the water. This tube can be revolved in any direction, and by observing it the commander of the submarine vessel can obtain a full view of what is going on in any direction. In order to keep the boat at the exact level below the surface desired, a pump ejects or injects

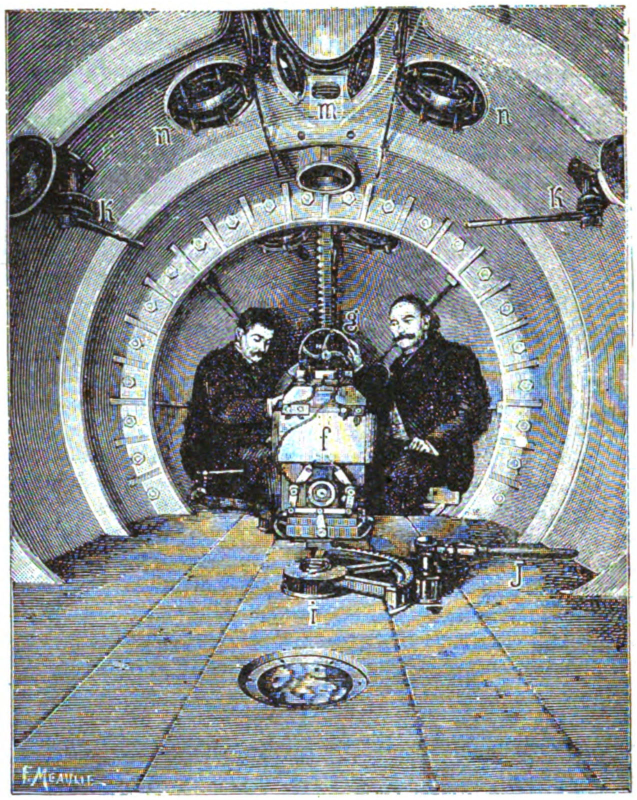

Fig. 3.—"Le Goubet."—Looking Towards the Stern.

water into the bottom. This pump is operated in one direction or another automatically by the position of the needle of a pressure gauge.

Electric energy is supplied by bi-sulphate of mercury cells, which the inventor has selected in preference to accumulators, owing to the fact that in spite of all precautions hydrogen is disengaged, which is not only bad for breathing but also introduces the danger of explosive gases into the boat, which may be fired by a spark from the motors.

TERMS OFFERED FOR THE NEW SYSTEM IN CLEVELAND, O.

The Everett system of street railways, which is proposing to build traction lines in Cleveland, has offered to sell 3 tickets for 10 cents, 8 tickets for 25 cents, and 32 for $1, with free transfers; to limit the hours of work for motormen to 10 per day with pay at the rate of $1.90 a day for 10 months, and $2.10 thereafter, to maintain a car service equal to any now given on existing lines in Cleveland; and to take a franchise for 25 years, at the expiration of which the city may purchase the property at its appraised value, to be determined by arbitration. Should the company retain the franchise for more than twenty-five years, the subsequent renewals shall be for periods not exceeding five years. Moreover, the company binds itself not to consolidate with other existing companies without the consent of the city. The Mayor of Cleveland has agreed to these provisions, but will insist on a track tax also.

PHILADELPHIA MUNICIPAL CARS.

A bill is now before the Philadelphia City Councils, for the purchase by the city of the Frankford and Southwark Passenger Railway at $645,538.37, and authorizing the city to purchase at that price and lease to the best bidder for a term of ten years. The lessee is to pay as a bonus to the city the money to be paid the company, fulfill all conditions required of the present company, and give free transfers on fares not exceeding five cents. The bidding is to be based on the proportion of gross earnings to be paid the city.

ELECTRIC TRACTION ON BROOKLYN BRIDGE.

The general plan for the trial electric cars on Brooklyn Bridge is to mount four fifty horse power motors on the axles of one car of each train. These passenger car locomotives will remain with the trains at all times, and will switch the trains from the incoming to the outgoing platform and to the tilting sheaves, where the trains are attached to the cable. If, while ascending the 3.78 per cent. grade, the grips should slip and the train be in danger of stopping, the electric motors can be employed to assist the train over the summit.

During the early morning hours, when the cable is not running, the trains may be operated entirely by electric motors. By supplying each train with its own facilities for switching, the interference of the locomotives with the incoming and outgoing trains will be avoided and the complexity of the switching reduced one-half.

The four motors are of the General Electric 1,200 type, adapted to this equipment. Each motor weighs about 3,000 pounds, and will exert a draw-bar pull of 1,320 pounds, at eleven miles an hour. The frame of the motor and the gearing are of steel. The motor is suspended so as to relieve the axle of nearly all weight. The trucks are of the same style as used on the Chicago West Side Elevated Road, and have the combined advantages of a passenger and locomotive truck. They are made by the McGuire Manufacturing Company of Chicago. The controlling apparatus is in duplicate, and the motors can be operated from either platform. In order to avoid obstructing the platform, the controllers are located underneath the car body. These controllers are of the well-known L 4 type, which have given satisfactory service in Chicago. Each controller can operate the four motors, or any two of them, as desired.

It is also the desire of the trustees to heat the cars by electricity, and twelve electric heaters will be placed in each car. These heaters, made by the Consolidated Car Heating Company of Albany, have a maximum capacity of 40 square feet of radiating surface at 400° Fahrenheit. Five degrees of heat can be obtained by means of a controlling switch.

The electric car-lighting system of the bridge, is equipped with apparatus nearly all of which was made by the General Electric Company, and has given entire satisfaction since its installation, nearly a year ago.

OBITUARY.

THOMAS MARTIN.

The death is announced by cable of Mr. Thomas Martin, J. P., of Gravesend, England, father of one of the editors of THE ELECTRICAL ENGINEER. The deceased, whose family had long been connected with the old East India Co., began active life in the service of the English Trinity House, for whom he did a great deal of work in re-charting the North Sea. This important task led to his being attached for special navigation duties to the British Baltic fleet in the Russian War, and also brought him in close touch and friendship with many of the early submarine cable promoters and engineers on both sides of the Atlantic, including those interested in the "Great Eastern," which was entrusted to his care in English waters. His acquaintance with sea floors was intimate, and he was frequently consulted as to buoying, grappling and currents. For nearly the last quarter of a century he had been in charge of the deep sea pilotage of the Peninsular & Oriental Steamship Co., which has the finest fleet of steamers sailing under the British flag. Mr. Martin had also been in the Commission of the Peace for several years. He leaves a widow, niece of Dr. Samuel Smiles, the biographer of Stephenson, and author of "Self Help."

DR. F. W. SHAIN.

It is with extreme regret we record the death of Dr. F. W. Shain, of Jersey City, who was thrown from his buggy last week and never recovered consciousness. He was 45 years of age and at one time member of the Board of Education. As the brother of Mr. C. D. Shain he had a large circle of acquaintance among electrical men, by all of whom he was highly appreciated for his many manly qualities.

JOHN W. DUXBURY.

John W. Duxbury, superintendent of the Central Division of the New England Telephone and Telegraph Company, died on Jan. 13, at Lowell, Mass. Although in declining health for a year, he attended to his duties until last Thursday, when he strength failed. He leaves a wife and two daughters. Mr. Duxbury was born in Dover, N. H., Oct. 4, 1844. He received his early education in that place and was graduated from Bowdoin college in 1863. He immediately entered the employ of the Western Union Telegraph Company, and in a short time became connected with the army telegraph corps at Chattanooga, where, though only 19, he had full charge.

After the war Mr. Duxbury re-entered the employ of the Western Union Company and later he was connected with the Providence telephone exchange. Entering the New England Telephone and Telegraph Company as assistant manager he was six years ago appointed superintendent of the central division of the company with headquarters in Lowell.

GEN. EDWARD B. FOWLER.

Gen. Edward B. Fowler, the war Colonel of the "fighting" Fourteenth Regiment, died on Jan. 16 at his home in Brooklyn. He was prostrated with paralysis about three months ago, and from the beginning of his illness there has been no hope of his recovery.

Gen. Fowler belonged to an old English family which settled at Hempstead, L. I., over a hundred years ago. He was born in New York City in 1827 and when a boy moved to Brooklyn with his parents. While still attending school he joined a youthful patriotic corps known as the "Union Blues." Two years later, when the Fourteenth Regiment was organized, he joined it with the rank of Lieutenant. His promotion was rapid, and when the war broke out he held the position of Lieutenant-Colonel. He was with the "Fighting Fourteenth" all through the war. He assumed command of the regiment at the second battle of Bull Run, and led it with conspicuous bravery in the many engagements in which it participated. His "red-legged devils" and their brilliant deeds are one of the glorious memories of the war.

He was twice severely wounded, but did not return home

GEN. EDWARD B. FOWLER.

until the regiment was mustered out of the service on June 6, 1864, when he retired with the rank of brevet Brigadier General. He resigned the command of the regiment in 1866, but until recently had been President of the War Veterans' Association of the regiment.

Soon after the close of the war Gen. Fowler was given a responsible place in the Custom House, and held it a long time. Subsequently he was connected with several banks, chief clerk of the Brooklyn Board of Audit, Treasurer of the Atlantic and Pacific Telegraph Company, and chief clerk in the Internal Revenue Department in Brooklyn. He was auditor of the Commercial Cable Company at the time of his death. Gen. Fowler was always an ardent Republican.

The deceased leaves a widow, a daughter, Mrs. W. H. Baker, wife of the vice-president of the Postal Telegraph Co., and a son, Edward Fowler.

The funeral services were held on Sunday afternoon in the Simpson Methodist Episcopal Church, after the body had lain in state in the Brooklyn City Hall. Among the pallbearers were Gen. B. F. Tracy, Gen. John B. Woodward, Gen. Butterfield, Gen. McLeer, Gen. Theodore B. Gates, the Hon. Seth Low, Mr. A. B. Chandler and Mr. George G. Ward. We are indebted to Mr. J. B. Tattavall, of the *Telegraph Age*, for the excellent portrait herewith.

CONTENTS.

PHOTOGRAPHY THROUGH OPAQUE BODIES.

WORLDWIDE attention has been aroused by the reports of the work done by Prof. Rontgen in taking photographs electrically of articles screened by solid objects. In our present issue we print an article by Mr. Georges d'Infreville, the well known electrical engineer and inventor, in which he advances what we may perhaps call his claims to priority in this respect; and in which he also makes some remarkable statements as to the ability to see electrically in darkness. We are sorry that Mr. d'Infreville is not at liberty to go into further details, but we are constrained to say that in this article he makes no assertion that he has not been making, confidentially, for a long time past—to our knowledge, for many months. This seems to us to be another of those instances where a good many people are working on one line, and are greatly surprised or even mortified to learn, from a sudden disclosure, that they have not got the field entirely to themselves. Mr. d'Infreville and the others working upon the subject of "phosphotography" and "phosphorescent" or "etheric" lighting in general, have our heartiest good wishes for an early fruition of all their hopes and dreams.

THE INSTITUTE 1,000 STRONG.

IT is with no small pleasure that we record the fact that within the present month the Institute has reached a membership 1,000 strong. This result has been accomplished in less than 12 years, and represents normal healthy growth throughout the last 10. They who have labored for the welfare of the Institute, and have borne the burden and heat of the day, have certainly much to encourage them in such a showing and also in the useful, dignified position of the Institute to-day.

Still, there is much that remains to be done, and some ideas for the future are suggested by the action of the American Society of Civil Engineers at its annual meeting last week. For many years past, that Society has owned and occupied a fine house on Twenty-Third Street, but it has now reached a membership of 2,000 and has thus outgrown its quarters. Under these circumstances, the Society has bought real estate at Broadway and Eighth Avenue (Fifty-ninth Street and Central Park) and will erect a $400,000 building which is to embody the latest beauties of architecture as well as the latest facilities for library, museum, &c. It seems to us that such a move brings up again the old project for closer engineering union and co-operation. Only in such a fireproof structure standing apart can a library and museum be properly kept; and neither the old house of the Civil Engineers nor the newer house of the Mechanicals is fit or safe as a repository for the treasures and relics rapidly accumulating. In the case of the Electricals, they have dodged from pillar to post, have shared the hospitality of both of the other societies, and now have a small niche in the cock loft of the Havemeyer Building, where things are very comfortable but by no means stately.

Until the conditions are inviting, the Institute will not receive the many donations of books and papers intended for it nor will it be made the custodian of the large variety of electrical relics and models that should properly be in

its care and keeping. We see no good reason, therefore, why the Institute should not endeavor to meet the other societies at this juncture in an endeavor to put up a building worthy of all and able to accommodate all. The opportunity is so good, we should be very sorry if no effort is made to benefit by it. As times grow better, members will be able to assist in the work by their liberality, but even on a plain business basis the various bodies of engineers should be able to secure a central union building which is at once a home, a museum, a library, and a safe deposit for the property and publications of them all.

SLOW SPEED DIRECT-CONNECTED ENGINES.

THE last five years have witnessed a remarkable growth in the application of direct connected engines to the driving of dynamos both large and small; and in the latter case particularly, direct driving has become somewhat of a fad. Not all engineers, indeed, are agreed upon the superiority of small direct connected units and many are still of the opinion that the belt-driven dynamo running at 1,000 revolutions or thereabout has been unnecessarily crowded into the background. Engine builders, also, have not all entered the field of direct driving voluntarily and in many cases may be said to have been pushed to it by the desire to meet a demand created largely by competition. Those who favor belt driving argue, not without some reason, that the direct-connected unit forces both the steam engine builder and the dynamo constructor to adopt methods which militate against either the cost or the efficiency of their respective apparatuses in order to adapt them to each other; as a result a reaction is already beginning to be noticeable, looking to a lessening of the difference in speed requirements. A most most notable example of this kind is the type of geared engine designed by Mr. Elmer A. Sperry, which is described elsewhere in this issue. With the arrangement there adopted, a ratio of two to one is obtainable between the speed of dynamo and engine, a decided gain, as it permits of the employment of a slower speed engine or a higher speed dynamo or a combination of both, as compared with present direct connected practice. The last word on dynamo driving has by no means been said, and the progress of Mr. Sperry's method will be watched with keen interest by electrical engineers.

ELECTRIC TRACTION ON THE ERIE CANAL.

ONE of the most interesting as well as important public documents recently coming under our notice is the report of State Electrician C. R. Barnes, containing the results of experiments on canal boat traction carried out with the Lamb towing system at Tonawanda, as recently described in our columns. These experiments were carried out with a scow having a displacement of 217½ tons and drawing 5½ feet of water, the run being made over a distance of 2,145 feet or 0.4062 mile. Notwithstanding the fact that the vessel used was a scow, which for a given displacement offers more resistance than an ordinary canal boat, and also that the motor employed was only taxed to one-third of its rated capacity and that its efficiency was still further impaired by fluctuation in the potential of the railway current during the test, an average speed of about 2½ miles per hour was obtained, with the expenditure of only 8½ electrical horse power. With these figures as a basis Mr. Barnes shows that at the price at which the Erie Canal Traction Co. is bound by virtue of its franchise to furnish electric power to boatmen, namely, not to exceed $20 per H. P. per season of navigation, with a boat making 35 single trips between Buffalo and Troy, the cost per trip at the speed referred to would be less than $5.00 or 1.4 cents per mile. Assuming that during one-third of the entire time the motor remained idle at the locks and elsewhere, although power was charged for just the same, the cost per boat mile covered would average 2.1 cents or $7.66 per trip. Still further, adding a rental charge for the motor, the total cost would amount to 4.2 cents per mile or $15.32 a trip. Mr. Barnes considers this estimate a very conservative one, and believes that at this rate not only would power be cheaper to the consumer, but the renting out of motors would prove a profitable enterprise. He also shows that if it were desirable to run at the speed of 3½ miles instead of 2½ miles per hour, the power would be increased from 8½ to about 23.4 electric H. P., which would make the cost 8$\frac{2}{10}$ cents per mile, or $29.93 per trip. It must be borne in mind that all these calculations are based as a result of the first test of the system. There is very little doubt that when the apparatus has been thoroughly adapted to its work these figures will show a decided reduction, but even as they stand they are a sufficient indication to warrant the belief that electric canal boat towing on the Erie canal for its entire length is now only a question of a comparatively short space of time.

MODERN APPARATUS vs. EXISTING CONDITIONS.

UNDER the above title Mr. W. J. Buckley in a paper read before the Northwestern Electrical Association, printed elsewhere in this issue, has brought together a number of home truths which we earnestly recommend to the attention of every central station manager. Mr. Buckley has done well to give particular prominence to the Welsbach burner and its influence on the income of lighting stations, for there is no subject now more seriously engaging the attention of many central station managers than the combating of this new foe to dividends. Mr. Buckley suggests various expedients for counteracting the influence of the Welsbach, such as a cut in rates, the application of incandescent lamps ranging from 100 to 500 candle power, or, if necessary, the buying up of, or selling out to, the gas company. There may be virtue in either or all of these suggested remedies, but we think the keynote is struck in Mr. Buckley's suggestion that the incandescent lamps be increased to a "competitive brilliancy." Mr. Buckley evidently implies thereby the raising of the candle power beyond the normal and justifies this expedient by the present comparatively low cost of incandescent lamps. As an expedient, pure and simple, we have no fault to find with the suggestion, but does it not imply a pre-existing weakness in any system that compels the adoption of a temporary measure of this nature? Mr. Buckley says with much truth, that the public are willing to pay one-fourth to one-half more for electric light than for gas, *provided they get full candle power*, and herein, we think, lies the key to the whole situation. If instead of giving the candle power of lamps a temporary "boost" during a limited period of time, the practice be adopted of renewing all lamps as soon as they fall below, say, 12 candle power, neither the Welsbach nor any other type of gas-light thus far presented to the public could successfully compete with the incandescent lamp. Careful station managers have long since recognized this fact, and in the best paying stations lamps are renewed free as often as the customer calls for them; while in not a few instances the companies themselves make regular periodic inspections and without solicitation renew defective lamps. All this appears so axiomatic as a factor in successful central station management as scarcely to require pointing out at this late day, with lamps selling at 18 cents apiece; but we are convinced that the losses of nonpaying stations will on examination be found to bear a direct ratio to the candle power of the lamps on their circuits. It may still require time to bring home the lesson of "full candle-power" to the rank and file, but until that becomes the goal to be striven for, dividends may have to wait on assessments.

Mechanical.

THE SPERRY SLOW SPEED ENGINE FOR DIRECT DRIVING.

It is probably not beyond the bounds of truth to say that no industry has had a greater influence on stationary steam engineering than electric generation and distribution. From the Edison Jumbo, to belting and later back again to direct connection, all served to show the changes which a new industry can bring about within a comparatively short time. But notwithstanding the present popularity of the direct connected high speed engine there are some who believe that better results can be attained with engines moving at slower speed with Corliss valve gear, and which are not subject to the wear and tear of high speed engines. Thus far the belt has been the only means by which this seems possible, but in a recent patent Mr. Elmer A. Sperry shows a type of engine which is so designed that a comparatively slow-moving piston in connection with a Corliss valve gear can without change of stroke or other relations employed with the highest economies, be made to give double the rotative speed as compared with engines coupled in the ordinary manner. This allows electric generators to be built of only half the size, weight and cost of those now required for a given service at the speeds in vogue at present. The manner in which Mr. Sperry has carried out this design is shown in Fig. 1, which illustrates his new type of engine, while Fig. 3 shows an enlarged view of its principal operating parts.

As will be seen, the reciprocation of the piston is transformed into rotary motion of the crank through the oscillation of the articulating-links, the axis of the crank-shaft lying practically in the projection of the middle line of the oscillation of the links. One of the links being anchored at the fulcrum or gudgeon, the free end of the other link vibrates to and from this gudgeon and hence turns the crank by this vibration, which occurs twice for every single oscillation of the links. The free end being connected to the crank by the pitman the crank-shaft is given two revolutions for each double stroke of the piston, and at the same time the length of the stroke of the pitman and piston may be held on an equality or may be made to vary in any desired ratio to each other. When these ratios are equal, the strength of the parts—for instance, the crank-shaft, pillow-block, crank-pin, pitman, etc.—need not be materially altered from the best practice in the ordinary type of engine. This, it will readily be understood, would not be the case if, for instance, the piston was attached to the oscillating links at their articulating-point. In this case the strokes of the pitman for anything like the best distribution of strains would have to be far less than the length of the stroke of the piston, and would therefore have to be made very much heavier for an engine of a given piston-speed, and furthermore the limitation which by far is the greatest in present engines would in no wise be overcome, but would on the other hand be aggravated. The attachment of the piston to a point on the lever intermediate between the fulcrum and the articulating-point or any method with the arrangement shown whereby the stroke-lengths of the pitman and piston may if required be rendered equal and allowed to vary from this point either way, is considered by Mr. Sperry to be one of the essential parts of the system.

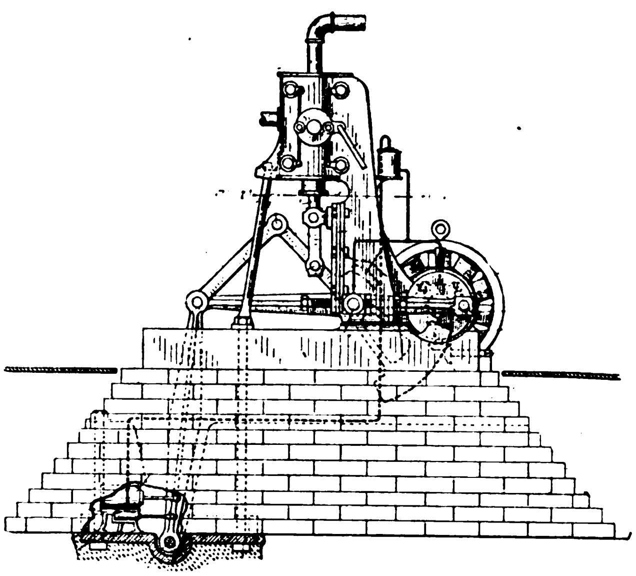

Fig. 1.—The Sperry Slow Speed Engine for Direct Driving.

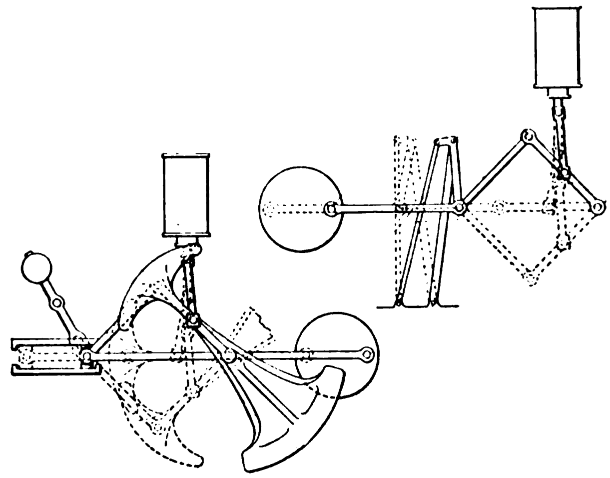

Figs. 2 and 3.

To illustrate the function of the masses and counterweights attached to and forming a part of the oscillating or reciprocating elements, Mr. Sperry takes a case of a 400 H. P. engine making one hundred double strokes of the piston and two hundred revolutions of the crank-shaft. The articulating-point between the lever and the link, Fig. 2, will be found to attain a velocity of about fifty-two feet per second crossing the centre line of its oscillation—that is, in half a stroke it has attained approximately this velocity. It has been found that the weight of the vibrating masses should be such that at this central point they will have absorbed in their acceleration a considerable percentage of the energy delivered from the source of power. This should for most instances exceed thirty to fifty per cent. of the power. With high velocities light parts will fulfill these requirements. It may be with advantage increased considerably beyond this point, but should not be decreased very much below it, although farther experience may lead to a wider variation for special purposes.

In the case cited one ton at this point may be made to absorb 165.6 horse-power seconds. The energy stored up in the moving masses at this point is delivered by them to the pitman and crank-shaft in the last half of the stroke. In this region the pressures due to early cut-off, expansion of steam or other causes would otherwise be materially lessened, the advantage of this arrangement being a very even distribution of the pressures on the crank-pin through both halves of each stroke. The increase in weight of the oscillating mass furthermore tends to neutralize the lunge or tendency to pound and to give a more uniform movement while passing the centre of oscillation, at which point the strains are reversed. Both these points have been found essential and necessary, not only to smooth running but for economical construction.

Telephony and Telegraphy.

SCRIBNER'S METHOD OF AVOIDING SIDE TONES IN TELEPHONE TRANSMITTERS.

As is well known, the telephone-receiver at a station is included in circuit with the secondary helix of an induction-coil whose primary helix is in the circuit of the microphone at the same station, so that disturbances or vibrations of the microphone are reproduced in its own telephone-receiver, such sounds being designated "side tones." The side tones may be either noises arising from accidental vibration or jarring of the microphone or the vocal sounds spoken by the user of the microphone. The noises produced by the jarring of a powerful transmitter

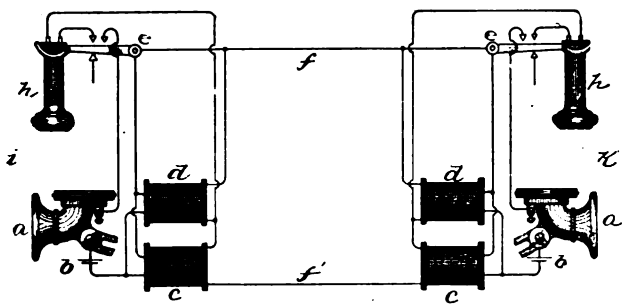

Fig. 1.

are frequently sufficiently loud to mask or obscure the articulate sounds reproduced in the receiver when it is in use, while the sounds reproduced in the receiver during the use of the corresponding microphone are so loud as to make the close application of the telephone to the ear unpleasant or injurious, while if the receiver be momentarily removed to avoid the loud sound the reply from the distant station may be lost. To avoid this inconvenience, Mr. C. E. Scribner, the well-known inventor of Chicago, has designed the arrangement illustrated in Fig. 1 and shown diagramatically in Fig. 2. The microphone *a* is included in a local circuit with the battery *b* and with the primary helices *c′* and *d′* of two induction-coils *c* and *d*

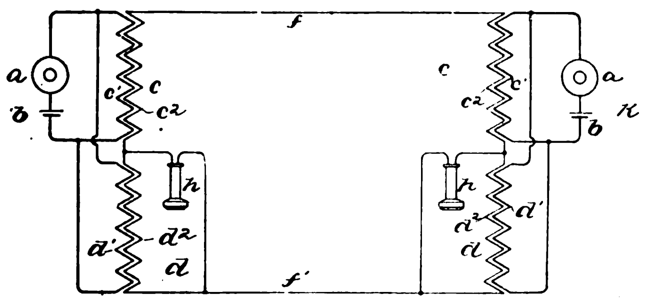

Fig. 2.

the primary helices being placed in parallel branches of the local circuit.

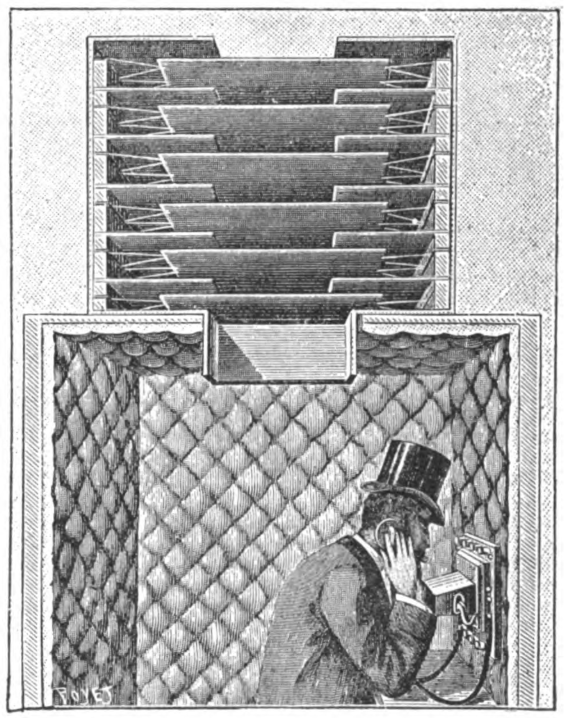
As seen in Fig. 1, the microphone-circuit is connected with the contact-points of a telephone-switch *e* by which it is closed when the telephone is removed from the switch-hook, in the usual way. The secondary helices c^2 and d^2 of the induction-coils *c* and *d* are connected in series in the line-circuit *f f′*. The telephone-receiver *h* is placed in a branch of the line-circuit in parallel with the secondary helix d^2. The connections of the primary circuits with the local circuit are so made that undulatory currents through the primary helices *c′ d′* induce currents in their respective secondary helices c^2 d^2 in the same direction in the line-circuit, as indicated by the arrows in Fig. 2.

The mutual inductions between the primary and secondary helices of the respective induction-coils *c* and *d* are so adjusted that with a given resistance in the line *f f′* no difference of potential exists between the terminals of the secondary helix d^2 while undulatory current is circulating in the primary circuit. Under this condition no current will flow through the telephone-receiver *h*, and hence no side tone will be produced therein. The coil d^2 thus produces no useful current in the line-circuit, but contributes only sufficient electromotive force to overcome its own resistance, thus permitting the helix c^2 of the induction-coil *c* to impress its full electromotive force upon the line-circuit *f f′*, creating current through the instruments at the distant or receiving station.

The secondary helix d^2 is made of high impedance, by making it of many turns of fine wire and placing in its field a considerable mass of iron, the effect of the high impedance being to prevent any considerable portion of the rapidly-changing telephonic currents flowing from a distant station through the line-circuit *f f′* from being shunted from the telephone-receiver *h* through the helix d^2.

THE MENIER VENTILATED TELEPHONE BOOTH.

Telephone booths, as is well known, are constructed so as to deaden the sound, in order to prevent the conversation from being heard on the outside. The means employed to effect this purpose have in the past given rise to much discomfort, by the absolute lack of ventilation which becomes noticeable, even after but a few minutes' sojourn in one of these booths. Our readers will, therefore, be interested in a very novel device, devised by Mr. H. Menier, of Paris, which we illustrate in the accompanying engraving, taken from *La Nature*, the object of



The Menier Ventilated Telephone Booth.

which is to afford complete secrecy for the telephonic communication, while at the same time permitting of the ventilation of the booth.

As is shown in the accompanying illustration, the top of the booth has a large opening, over which is placed a box open at both ends. Within this box are placed, at regular intervals, thin boards covered with cloth, let into the sides of the box, with openings of the same size as the hole in the roof of the booth. Other thin boards, also covered with cloth, are supported by cords from the sides of the

box, and are placed between the boards above mentioned, which are attached to the sides of the box. This arrangement allows the free circulation of air from the top of the booth, while experience has shown that it shuts in all sound.

In order to assure himself of the latter condition, Mr. Menier installed an apparatus of this kind over an opening in the wall, separating two rooms, and it was found that two persons, one in each room, placed one metre from either end of the sound deadening box were not able to converse, even in a loud tone of voice.

ELECTROLYSIS OF PITTSBURGH TELEPHONE CABLES.

A special dispatch from Pittsburgh of Jan. 13 says:—Every underground cable in Alleghany City, all underground wires in Bellefield, and part of the system of East Liberty and of the West End, have been abandoned, the down town district practically being the only part of the system in the two cities that has escaped the ravages of electrolysis. The wires affected are the property of the Central District and Printing Telegraph Company, otherwise known as the local telephone company. The wires had recently been placed underground at a cost exceeding $50,000. The water companies, telegraph companies, electric light companies, natural and artificial gas companies have also suffered to a large extent.

TYPICAL NEW YORK TELEPHONE LEGISLATION.

The usual fight against telephone corporations of New York State has begun in the Legislature. Assemblyman Cain of Brooklyn has introduced a bill creating a State commission to consist of the Comptroller, Attorney General and the State Engineer and Surveyor, who are to meet at Albany once a month and investigate all complaints by or against telephone companies and make rules and orders for the carrying out of the law. They may employ a stenographer at a salary of $2,000 and may hire expert accountants to examine the books of telephone corporations. The entire expenses of the commission shall be paid by the telephone corporations, in the same manner as the expenses of the Railroad Commission are paid by the railroad corporations. Telephone corporations are required under the bill to make an annual sworn statement, upon blanks furnished by the commission, of their receipts and disbursements for the year. The charges to subscribers, which are intended to be of such a nature as to net the companies a profit of at least 10 per cent. upon their capital stock, are as follows: Cities of 1,000,000 or over, $85 a year; cities of 500,000, $75; cities of 100,000, $48; cities of 20,000, $36; places of 8,000, $30; all other places, $27. Charge at pay stations, 10 cents for the first five minutes, and 5 cents for each five minutes after, for local distances.

What was known last year as the "Gerst telephone bill," which regulated the charges in all cities, was similar to this bill except that the charges in the Cain bill are about $12 a year higher.

THE HARRISON TELEPHONE CO. IN DUBUQUE, IA.

A special dispatch from Dubuque, of Jan. 8 says:—The Harrison Telephone company that started to establish an exchange in this city some time ago got the worst blow in a Kansas City justice court that it has yet received anywhere. A stock broker of that city had stock of a face value of $20,000. He sold it for $200 cash. The man he sold it to brought action against him for obtaining money under false pretenses. The justice reserved his decision. If he finds that the stock is worth even 1 cent on the dollar the defendant will be released. The company still seems to have a nominal existence, but it begins to look now as though all the millions of stock it issued would be of greater value if the paper on which the shares are printed were blank.

Mr. A. W. Prior has resigned the position of manager of the Macon Telephone exchange. He will go to Pennsylvania to engage in the manufacture of electrical apparatus.

Providence, R. I.—In addition to its fine new exchange, illustrated in The Electrical Engineer last week, the Providence Telephone Co. is putting up a building at Pawtucket for its own exclusive use, to be one story in height, and to be fireproof in every respect.

OUR "NEW YORK EDISON" ARTICLE.

Mr. Chas. L. Clarke, writing of The Electrical Engineer of Jan. 8, and its description of the New York Edison stations says:—"It looks like one of the most complete articles on a commercial electric light and power plant, in its technical and business aspects, that has ever been published. I like its direct and simple style. It appeals to me as a practical engineer."

MISCELLANEOUS.

CONCENTRIC WIRING.[1]—II.

BY SAM. MAVOR.

There is a steadily growing dissatisfaction with the generally adopted practice of enclosing the conductors in wood casings, and a steadily growing conviction that something better might be done. In most factories and warehouses it is possible to have the casings laid upon the surface, but in dwelling-houses, or in good hotels or clubs it should not be tolerated. Everyone is familiar with the unsightly wood casings and clumsy crockery ware which disfigures so many of the best hotels and other buildings in this country. How often we hear that electric light is not adopted because of the dread of the wood casings, and the cutting about and disturbance which their erection involves! Those casings are a standing reproach to the people who erect them. One has only to see the interior of a good building which a contractor has dared to wire on the prescribed lines with wood casing to realize how utterly unsatisfactory is the system. Those hideous casings are entirely out of harmony with their surroundings, and offend the eye at every turn. They blunder across ceilings and cornices, intrude upon decorative panels, and push their ruthless way through frieze and dado; while out of sight beneath the floors the joists are cut away to clear the casings until the margin of strength is often perilously low. The truth of the matter—and we all know it—is that we cannot carry out the wiring of, for example, a private residence in compliance with the recognized rules for double wiring and wood casing without excessive cutting of floors and plaster work, and disfigurement of walls and ceilings. At every turn we have to compromise between the decorations of the house and the fire insurance rules, and the concessions must needs be generally in favor of the decorations. In short, the modifications of the rules require to be so many and important that this system of wood casing is one which cannot be consistently and thoroughly carried out.

When the usual double wiring is carried out in situations where moisture charged with acid from cemented or plastered walls of interiors, or in such buildings as paper mills, wet spinning mills, dye houses, breweries, distilleries, chemical works, and the like, the destruction of the insulation is only a matter of time, and the casing, by harboring the moisture around the conductors, hastens the process. After the insulation has broken down, electrolysis, assisted by the acidulated moisture, takes place, and deposits away the copper of one of the conductors, with the consequent risk of heating and ultimately of sparking. The presence of moisture being a necessary condition of the development of such faults, the dampness of the surroundings of the conductors greatly reduces the danger of fire, but that the risk is not absent is proved by the charred and burned casing or woodwork found at such places. It must be remembered, however, that heating due to diminished section of the conductor may occur at a time when the moisture which caused the fault has disappeared, and this is a danger which no amount of fuses will modify. How can you ensure that your woodcased conductors shall never be subjected to such conditions? And how many of your average wireman's joints would stand 24 hours' immersion in water or soaking in moisture? The miserably futile expedient of attempting to waterproof the casings with putty and varnish is sometimes resorted to; such makeshifts are too childish. Lead-covered conductors are occasionally used where much moisture has to be encountered. But these for double wiring are a mistake, unless the positive and negative wires are both enclosed in the same lead sheathing. The objection to separate lead-covered conductors is that, if there should be an earth or leak on the negative wire, and the lead and insulation of the positive wire becomes punctured at a damp situation, the lead becomes charged positively, and will be deposited away over its whole length where moisture is present to assist electrolysis. This remark has no application to lead-covered conductors on board ship, where the lead sheathing is throughout in intimate contact with the hull of the ship, nor to lead-covered concentric conductors. This liability to injury from moisture is the fatal weakness of the ordinary wood-cased system. It is of much greater consequence to obtain a moderately high insulation, which may be relied upon to be durable, than to have—as can easily be had in a dry building—an insulation resistance of many megohms, which will disappear on the approach of the charwoman and her wash-bucket, or is at the mercy of the first loose slate or leaky water-pipe. What a common experience it is to discover wiring faults in the fungus-grown casings in damp and mouldy basements, or upon the "sweating" surfaces of cemented walls or ceilings! A fault which developed a few weeks ago in the writer's office is a good illustration of the weakness of the present double-wiring practice. The walls are covered with a light-green paper, which on one side of the room is pasted to a wooden partition, and through this partition and paper the conductors are led to a switch. Behind the base of this switch sparking was observed. On examination it was found that in our humid

climate the paper had absorbed moisture from the atmosphere, and this moisture, charged with an acid held in the paper, had attacked and destroyed, first the insulation of the conductors, and then the copper, until of the latter only a green sulphate remained, and the circuit was interrupted. As only one lamp was in circuit the spark was small and the heating effect slight, but under other conditions the results might have been serious. This is an interesting example of a fault developing in an apparently dry and well-aired and warmed room, and under the eyes of one whose business it is to avoid such faults, and to whom a spark was the first intimation of anything being wrong.

After wood casing, with its perviousness to moisture and other attendant disadvantages, the biggest blot on existing practice is the indiscriminate use of fuses. Some insurance people, and wiring contractors too, imagine that the risk of fire varies inversely as the number of fuses. The contrary is more near the truth. Fuses are not only a nuisance, they are apt to be a positive source of danger. The smaller number of fuses used the better; but they must be absolutely reliable, well mounted, and well placed. Most of the leading wiring contractors have adopted the distributing box plan of wiring, in which the branch fuses are grouped at the distributing centres. This system should now be compulsory. The use of isolated fuses should be strictly prohibited. The only inducement to use them is a trifling saving in the cost of conductors. The number of fuses should be kept down by keeping up the section of conductors. The larger expenditure on branch conductors entailed is amply repaid by the simplicity and uniformity secured. The dangers of diminishing the section of conductors and scattering fuses through a building are that the crockery fuse bases and cases are liable to breakage; the terminal screws are liable to become loose and so cause heating; and last, but most important, the danger of a conductor of too large area being used by an inexperienced or careless person instead of a *bona-fide* fuse, in which case the "fuse" is a delusion. This last danger is so real and so imminent that the insurance companies ought long ago to have prohibed the use of such fuses. The writer was recently in competition with a firm of contractors of large experience who do a great amount of wiring, and were in this case estimating for wiring about 200 lamps of 16 C. P. each. Samples of the conductors, &c., quoted for were invited along with the estimates, and our double-wiring friends submitted a sample of each of the *nine* sizes of insulated cables and wires, with their corresponding wood casings, and of each of the several sizes of fuses which they proposed to use. Nine different sizes of cables and wires were certainly not essential to the double wiring of this building, but they were part of the method of a much-experienced contractor, and his method is common to many others.

MODERN APPARATUS vs. EXISTING CONDITIONS.[1]

BY W. J. BUCKLEY.

Two things are constantly changing the conditions of your various plants, namely: the development of new apparatus, and the reduction in price of supplies. The money earning station fits its apparatus to its service; not the service to the apparatus. If you charge $10 a month for a 2,000 candle power arc lamp and your customer regards you as a robber, it would seem expedient to furnish either a smaller arc, or a big incandescent lamp service at meter rates, thus reducing the price, but not the proportionate profit. A big cut in your 2,000 candle power rates will transform that service into a non-paying investment, while a service of half the candle power at half the cost of production, will pay a profit.

The big incandescent lamp is a money making factor ignored by a majority of operating stations, either through lack of knowledge or appreciation of the fact that efficient 100 to 500 candle power lamps are selling at a price that commends their use.

Unless you are running a modern plant, it costs $6 per month to produce and maintain a 2,000 candle power arc lamp. This applies to the average station, and will be believed by the stockholder who has been in business long enough to see his intended investment enlarged, his plant rebuilt and his prospective profits used up long before they reach him in the form of a cash return, in expenditures necessary to meet unlooked for changes or unwelcome competition.

One of the chief elements of the latter is the Welsbach burner. This competition you have met in your various ways; yet you are all doubtless impressed with the fact that it has come to stay; not perhaps in its present form, but in a new and improved burner which eliminates some of the many glaring faults of the original. The quicker this competition is met, the easier and cheaper it is overcome. But how? Many men of many minds would have as many answers. The president of the Calumet Gas Company, of Chicago operating the second largest arc plant in this country, thinks the strongest competing service is an arc system in "blocks of five;" 500 candle power arc lamps, $\frac{5}{8}$ carbons, $5 per month, 5 per cent. discount when paid within five days after the first of the month.

1. Abstract of a paper read before the Northwestern Electrical Association, Milwaukee, Jan. 15-17, 1896.

In this consideration we may assume, first, it is unnecessary to bodily buy the Gas Company; or secondly sell your holdings at a sacrifice. If you can sell at a price and will not, we take it that you are running your station for the sake of your health, in which event, the Welsbach burner becomes a mere diversion breaking the monotony of an otherwise peaceful life.

The Welsbach fad strikes a town over night and goes through it like a dose of measles. It lasts about nine months, will usually displace one-third of your lamps in service, which, owing to the many objections of the burner, developed in its use, gradually return like lost sheep to the fold until the former output is reached, if not passed, by the demand created for a more liberal illumination.

The first change found necessary in your operation is to increase the candle power of your lamps to a competitive brilliancy. When 16 C. P. lamps sold at 85 cents this might prove disastrous, but with better lamps at 18 cents apiece, it becomes a necessary virtue. This will not decrease your profits as much as your first thought might suggest, for the increased voltage will run your meters fast enough to make up the added expense, provided you sell your current through meters. If you do not do so, the added revenues of those who do, would suggest that you climb in the band wagon and buy meters for your entire equipment. It is a money earning proposition to you and the satisfaction to your customer, who is pleased with his daily inspection of current used, even if the meter is 25 per cent. too busy.

In this connection the advisability of accurate switchboard instruments and their periodical calibration with a standardized instrument is clearly shown; as a comparison of the station output with the receipts, will immediately uncover any leakage in the revenue.

The increasing of your pressure will disclose, if your experience has not already proved it, the inefficiency of small transformers of any make. The ground losses on the line and the copper and iron losses in the transformers of the ordinary alternating station are uselessly and unnecessarily large. Four out of seven stations tested by me in the past three months for their constant load loss, have shown that less than two-thirds of the current generated reached the lamps. One station employing a 90 K. W. 1,800 light 1,000 volt alternator with 1,842 lamps wired, gave an output of 70 amperes at the switchboard when 840 lamps were burning. The lamps, which were all of one make, were counted between the hours of seven and eight P. M. when the customers were requested not to turn off or on any lamps in that interval. The test showed that current for 1,400 lamps had been generated at the station with a constant load loss of 28 amperes. This loss should not exceed 8 amperes. The current at the switchboard running 840 lamps should have registered as 50 amperes, all of which would indicate that this station ran with a constant load loss of 20 amperes, or current enough to supply 400, 16 C. P. lamps, for which the station received no pay. This useless loss was eliminated by putting triple petticoat porcelain insulators in place of the single petticoat S. G. glass; removing one fixed and one intermittent ground on the line and changing 1,400 lights of 5, 10 and 25 light 50-volt transformers to 2, 250-light, eight 100-light and two 50-light 100-volt transformers. The balance of 400 lights were on the residence circuit and were changed from 50 to 100 volt without materially decreasing the size of the transformers. When these changes were completed, the output at the switchboard was 51 amperes with 898 lamps burning. While formerly most of the output was sold at a given rate per lamp per month when the change was made, every lamp was put on meter, and a losing station converted into a paying property.

Increasing the candle power will apply to the same extent in meeting ordinary gas competition. We know the public is willing to pay a fourth to a half more for electric light than gas, provided they get full candle power. Taking gas and incandescent lamps at equal candle power, the equivalent rates would be as follows:

Gas	at	$1.00	per	thousand	equals	16 C. P.	lamps	at	½c. per hour.
"	"	1 50	"	"	"	"	"	"	¾c. " "
"	"	2.00	"	"	"	"	"	"	1c. " "

This presumption will certainly leave a fair margin of profits on a competitive basis, as the life of the incandescent lamp cuts but one fifth the figure it did four years ago. The pioneer usually forgets this change in lamp values, and through force of habit and training keeps down the incandescent candle power. A new rule hung on the switchboard should read "Keep up the Candle Power to Keep Your Job."

The following efficiencies of 100-volt 16 C. P. lamps is the result of a test made with some of the prominent makes:

Thomson-Houston	consuming	.62	amp.	or 62	watts	gives	3.875	watts	per C. P.
Edison	"	.55	"	" 55	"	"	3 437	"	"
Buckeye	"	.56	"	" 56	"	"	3 500	"	"
Packard	"	.57	"	" 57	"	"	3.562	"	"
Bernstein	"	.65	"	" 65	"	"	4.062	"	"
Beacon	"	.54	"	" 54	"	"	3.375	"	"
American	"	.58	"	" 58	"	"	3.625	"	"
Columbia	"	.61	"	" 61	"	"	3.800	"	"
Keystone	"	.56	"	" 56	"	"	3.500	"	"

The price delivered and the guaranteed life are other points which decide the preference, but I hesitate to include the life test through a dislike of a probable criticism of advertising some particular lamp; and again each batch of lamps filling a given order from almost any maker seems to vary from the average life of the preceding lot.

The "New Lamp," like the "New Woman," will curtail the material used in its construction and produce more effect with a given energy. A lamp having a life of 500 hours and taking $2\frac{1}{4}$ watts per candle-power at 18 cents apiece, or still better, a 300 hour 2-watt lamp will greatly increase our competitive strength.

The contingency arising from an opposition plant entering your field with neither your permission nor pleasure is, of course, governed by local conditions and your judgment.

Referring again to the Calumet Gas Co. as a successful fighter of competing plants, I will state that this Company has but one rule: fight from the shoulder. Drop the prices down at one stroke to a point where the other fellow must lose. Deprive him of all revenue and he is forced to quit. This rule has placed the price of 1,200 C. P. arc service in certain districts in Chicago at 10 cents per night, $2.60 a month.

It may be expedient to state that the Calumet Gas Co. has money and a modern plant. If you have neither, the value of fighting from the jump is not altered, as it forces you to draw on other resources to modernize your station, a good thing in itself, or without resources it compels a more liberal and immediate purchase of your plant.

To-day, power, arc and incandescent service, is produced from the same machine and any agreement to divide the service is liable to daily abrogation. The best protection to the value of your property and its revenue, is to keep it modernized. This contemplates a continuous expenditure anticipated and met by the money earning plants.

The development of the business has demonstrated the economy of large units. In arc service the 100 to 125 light machines have displaced the 35 to 50-light units with a saving in maintenance of 40 per cent. In direct current service, the large units effect a saving in maintenance of 20 per cent., which is increased up to 50 per cent. by being direct connected. In alternating current service, the large units effect a less apparent saving in current efficiency; but the slower speed, lower temperature, and ability to run continuously makes their adoption a commercial gain, apart from the simplification of circuits.

Speed and weight should govern the price of all types. A dynamo running at 600 revolutions weighs nearly twice as much as one of the same design and rated capacity at 1200 revolutions. It costs 70 per cent. more to build. Hence, a direct connected dynamo at 275 revolutions is worth 70 per cent. more than a belt driven machine of the same design at 550 revolutions. When the armature is built directly on the extension of the ordinary engine shaft, this may be reduced to 50 per cent. on account of the doing away with one box, pedestal and part of the frame.

Suppose a purchaser wants a direct current belted machine of 100 H. P. or 1000 lights capacity. He finds the cheapest type, a bipolar machine, say with a speed of 1200 revolutions, weight 6000 lbs., price $900, average efficiency 80 per cent., with an armature life of two years if loaded. In the multipolar machine he finds the high speed belted dynamo at 1,100 revolutions, weight 6,500 lbs., price $1,000, same efficiency and life as bipolar. The medium speed dynamo at 550 revolutions, weight 11,000 lbs., price $1,400, 85 per cent. efficiency, armature life five years. The slow speed 275 revolutions, weight 17,000 lbs., price $2,200, 87 per cent. efficiency, armature life eight years.

Thus we have dynamos of the same make, if you will, and each of the same rated capacity in horse power, lamps or kilowatts ranging from $900 to $2,200 in price; the more expensive machines not always receiving at your hands the consideration they deserve. The dimensions of the base frame of any dynamo will show when too great a preponderance of weight is delegated to that inanimate object.

Again the rating given a dynamo by the maker should not always be accepted. The various machines offered should be placed on the same basis for estimating their capacity, namely: assuming the highest point of efficiency at full load, the added capacity of the machine beyond that should be regarded as an overload. Most dynamos are rated at their utmost capacity, irrespective of efficiency or temperature.

A 150 K. W. alternating dynamo rated at 130 amperes and 1,150 volts is worth but 86 per cent. of one of equal quality rated at 150 amperes and 1,000 volts, the first being the output at the dynamo, the latter the output at the centre of distribution where it belongs. This difference in actual value is reduced to 75 per cent. if the first dynamo is rated at full capacity, and the latter at its most efficient output.

It may be a question of the value of money to you whether you can afford to buy slow speed machines at their increased cost. The Harrison Street station of the Chicago Edison Company has shown an extraordinary reduction in cost of current per kilowatt hour by the use of direct connected machinery; but the units are from 500 to 1,500 kilowatts. A fair estimate of the added saving in the use of direct connected apparatus would be in a

100	K. W.	machine	10	per cent.
200	"	"	20	"
300	"	"	30	"
500	"	"	40	"
1,000	"	"	50	"

In buying arc apparatus the speed and weight should also govern in nearly the same degree the price of the largest size you can use. The pressure which reaches 6,500 volts in a 125 light arc dynamo seems to be carried on the ordinary arc circuit as easily as 3,000 volts. Of course 6,000 volts will jump nearly twice as far and theoretically would require twice the insulation to hold; but experience has shown that if an overhead arc line is built to protect a pressure of 3,000 volts, it will carry 6,000 volts with safety. No reliance whatever is placed upon the insulation of the ordinary No. 6 overhead arc line, which should be erected as if the wire was bare; as almost all such lines five years after erection are bare, so far as insulating qualities are concerned. The weak spots requiring increased insulation are the wires from the pole to the lamp or entering stores. Beginning then at the pole these wires should be a high grade rubber insulation. The regular weather proof line wire will give constant trouble even when protected with porcelain or hard rubber bushings or flexible tubing. It is not necessary to use rubber insulation throughout your overhead arc line, even with 150-light arc machines.

When the purchaser comes to buy alternating apparatus he is confronted with single phase, quarter phase, two phase, three phase, multiphase and monocyclic, surely enough to phaze him to start with. (The author then gives a brief description of the various types of single phase, 2-phase, 3-phase and monocylic machines.)

You are all familiar with the difference of cost in erecting and maintaining two or more circuits instead of one or three wires instead of two; but some buyers neglect the consideration of this expense until their multiphase apparatus is purchased, when it confronts them with the nasty familiarity of the unexpected expenditure so usual in disbursing our wonderfully overestimated receipts.

Again at least one two-phase system advocates limiting the loss in line copper to 2 per cent., the alternative of having a greater line loss with a smaller expenditure of cash for copper, is, a reduction in the efficiency of the service and usually the use of condensers. It is Hobson's choice as to the amount of money required, though you might get time on apparatus, while copper is cash.

The phase affects the units in which your power is distributed. Impedance lag and idle currents develop as the size of the self-exciting motor increases, practically limiting the distribution of power on a single phase circuit to motors not exceeding in size 100 H. P.

The single phase generator may be a 1,000 horse power machine, but any one of the motors must not be larger than 100 horse power unless independently excited and started.

So far as the phases are concerned, the only conditions under which a multiphase system is more applicable than a single phase is in the transmission of very large amounts of power over great distances and where the power is distributed in several units. After the phases the important consideration is the number of alternations or the frequency.

Generally speaking the higher the frequency the better the lighting service. The frequency of 3600 alternations per minute or 30 cycles per second is suitable for power only and will not commercially operate an arc or incandescent service at all; because the low period current waves produce an undulating and decidedly fluctuating light. Power is practically limited between 20 and 150 cycles per second or 2400 and 18,000 alternations per minute, because lower frequencies reduce the speed and increase the weight of motors and transformers beyond a commercial economy, while higher frequencies mechanically prevent getting the necessary number of pole pieces within an efficient compass or radius.

Running any make of alternating arc lamp from the incandescent transformer has not yet produced a competitive arc service; and applying the known results to the plants represented in this Association, the application would resolve itself into the use of the regular arc dynamo and lamp where the number of lamps exceed forty. When an alternating station has an output of a few arc lamps by all means use the alternating arc with a special transformer permitting the use of the ordinary carbon, but when you can sell more than forty arc lamps, the saving of the current lost in conversion and the single wire circuit of the regular arc system must then commend itself.

The alternations also affect the ordinary transformer. But two makers to my knowledge build a transformer especially for 7,200 alternations. All the other manufacturers build a transformer designed for high frequencies; and without altering the patterns or construction beyond a few trivial changes to make room for the necessary added ampere turns of wire offer a transformer presumably suitable for any frequency.

How does this affect the man who buys transformers? If he has a high frequency current, this type of transformer will

consume 50 per cent. more magnetizing current than one designed only for high frequency. If he applies the high frequency transformer to the low frequency current the lack of necessary ampere turns of wire or weight in iron makes the loss in magnetizing current still greater and the transformer mighty hot.

The quick repair transformer wherein the iron field is split in two, so the coils can be readily replaced, is too dear at any price; the broken magnetic circuit causing too great a loss of current in energizing the transformer, apart from the charring of the insulation by the excessive heat generated.

It is an apt illustration of the eternal fitness of things that the electrical apparatus built to repair easily, soon develops a determined disposition to accommodate you.

Summing up the brief opinions offered might suggest to the members of this Association who are probable buyers of new apparatus:

1. If the amount and valuation of your money will permit, buy direct connected apparatus.

2. If your means or present arrangement of power suggests the purchase of belt driven dynamos, buy the heaviest slowest speed machine of the largest capacity practicable.

3. Use 2½-watt lamps; 2-watt if you can buy them.

4. If your power service is in small motors none of which are larger than 50 H. P. use single phase apparatus; if in motors larger than 50 H. P. use multiphase.

5. If the proportion of lights is greater than power, buy high frequency apparatus; if power is the most important service, buy low frequency.

6. Use the largest transformer practicable having the best regulation consistent with minimum loss on no load.

7. Sell all your current through meter, and check up the station output with your receipts.

These suggestions numerically arranged like the Commandments will not be taken, I trust, as advice. Advice is the cheapest thing I know of, and I value my opinions too highly to offer them to any but those who choose to entertain them.

THE UP-BUILDING OF THE SMALL TOWN.[1]

BY FRED DE LAND.

THOUGH we may not agree with the pessimistic side of the question Mr. Fletcher so ably presented in "The Doom of the Small Town," yet we must admit that he clearly pictured the silent tragedy that is being enacted in many towns and villages from whence the young, the hopeful, the more ambitious depart to seek more suitable abiding places, leaving the dullard, the ne'er-do-well, the rich-in-purse-but-poverty-struck-in-soul to rust on in unhelpful existence. And while citing many causes that may have led to present conditions his conclusion that: "Whatever be the causes, unless tendencies be arrested, the future of the small town is extremely discouraging, and it is very doubtful whether any material change in existing conditions will soon occur," is not nearly correct.

But the question I propounded to myself while reading this article was: Has Mr. Fletcher shown us only one side of the shield and that the dark side? Is it not possible to gather statistics relating to small towns that would have shown a condition of prosperity in many, even though such a showing would rob the first portion of his paper of much of its gloom? For there is nothing new in villages being deserted for towns more favorably located or offering greater advantages to the inhabitants. Such movements in our country can be traced as far back as A. D. 1700.

The reverse side of the shield shows that never before have so many small towns enjoyed modern improvements that not only tend to make life better worth the living, but also to increase property values out of all proportion to original investment. In the very States he mentions are towns of only six hundred, eight hundred and a thousand inhabitants with electrically lighted streets, with well kept roadways, and surrounded by that atmosphere of prosperity that attracts and invites the refined, the practical and the prosperous. In Michigan there are seventy-one incorporated cities varying in population from 287,837 (Detroit) to 746 (Gladwin) and in every city there is one or more electric lighting plants, which is not at all strange. But there are also 309 incorporated villages reporting a population in 1894 varying from 91 to 6,051. Of these 309 villages, nearly 100 have electrically lighted streets, though several reported a population considerably less than 1,000 souls. Compared with the census of 1890, the census of 1894 records a decrease in population in several towns and villages, but in no town of electrically lighted streets was any decrease reported, while the growth in some of these electrically lighted towns is almost marvellous.

Speaking to a Michigan merchant on this subject, he replied that in his town of nearly 3,500 inhabitants the marked growth in population and in prosperity had its inception in the order of the village board directing that electric lights be employed in illuminating the street at night. "Now the hanging of those big lamps in our streets has indirectly wrought as marvellous a change as often follows the placing of a new and attractive carpet in the reception-room of the old homestead. Gradually the old style furniture is replaced by the modern and more attractive until finally the room is modernized throughout, is artistic and comfortable. So it was in our town. The arc lights gave us a taste of progressiveness and awoke a desire for other improvements. Later the main streets were all paved with asphalt or with brick, and additional lamps were placed at street corners. Then some old frame stores that had been a fire menace for years were torn down and a modern office building erected on the site. These improvements furnished our local editor with a subject to talk about, and soon the fame of our house cleaning had penetrated every hamlet in the state. That this fame brought its own rewards is shown in the fact that we now have no less than seven factories, one of which employs 180 hands, and five large modern stores to say nothing of numerous small shops, two new school houses, three churches, while 583 new dwellings and other buildings have been erected since the arc lamps were placed in circuit, and when I consider how remarkable are the changes that have been wrought, and how we might still be jogging along in the old way had the dozen oil lamps not been displaced by the big white lights, I feel very grateful for the wisdom and the forethought that ordered the expenditure that proved to be so profitable an outlay."

This is a homely illustration but thoroughly sensible and practical, and one that many a village resident might profitably ponder.

The author gives additional instances of like nature and then continues:

Surely it is more pleasant to read instances of this character than it is the despondent conclusions Mr. Fletcher has presented in *The Forum*. And it requires no vivid stretch of the imagination to conclude that just as satisfactory experiences might have been recorded in some of the Massachusetts towns that report such a marked decrease in population during the past ten years. The State census report just issued shows a loss in the ten years intervening between 1885 and 1895 in 140 towns and villages. The streets of some of these villages and towns have never been lighted with electric lamps, and the decrease in population reported in each ranges from 5 per cent. to 25 per cent., while, on the contrary, many other villages have advanced rapidly in population. Millis, for instance from 683 to 1,006, or an increase of 47 per cent. from the day that modern progressive methods predominated. Millis, it is needless to state, is a town of electric lighted streets. Then there is Dudley with a gain of 17 per cent. in population, and a dozen other electric lighted villages all showing marked gains, while their neighbors puttering along with dark streets had slowly degenerated.

STORAGE BATTERIES IN CENTRAL STATIONS.[1]

BY MAURICE BARNETT.

THOSE who were present at the last convention of the Northwestern Electrical Association will recall the paper on "Storage Batteries in Railway Plants" read by Mr. G. Herbert Condict,—and will also recall that the paper in question did not excite any unusual discussion. At the Cleveland convention of the National Electric Light Association Mr. Nelson W. Perry reviewed the general aspects of the "Storage of Energy" and expressed what he considered to be the relative value of different forms of storage apparatus in a central station. So far as his remarks on the storage battery were concerned there was very little concurrence of opinion with him,—and the discussion that was started drew, from a number of practical electrical engineers, expressions that were favorable to the use of storage batteries in central stations. At the meeting of the American Institute of Electrical Engineers, held November 20th, 1895, not fewer than four able papers were read on the subject of storage batteries and the general consensus of opinion seemed to be that storage batteries, looked at either from the standpoint of first cost of general utility and economy in the station, were a decidedly valuable adjunct of central stations. Again, two years ago there was only one important storage battery plant in use in a central station in the United States, and station managers were not seriously considering the installation of this form of accessory apparatus. During the past two years very large battery plants have been placed in Boston, in New York, and in Lawrence, Massachusetts, by local Edison companies, while two battery installations have been made in Merrill, Wisconsin, and Anaconda, Montana, in connection with railway power plants. Since the first installation was completed at Lawrence, Massachusetts, the battery capacity has been doubled, and it is understood that the advisability of increasing the capacity of some of the other stations in the same way is conceded. Negotiations for storage plants for other central stations have been carried on for some time and will probably end in our seeing the number of existing battery plants very greatly increased.

1. Abstract of a paper read before the Northwestern Electrical Association, Milwaukee, Wis., January 15-17, 1896.

1. Abstract of a paper read before the Northwestern Electrical Association at Milwaukee, Wis., January 15-17, 1896.

What, it may be asked, has occasioned the change of attitude of electrical engineers and station managers towards the storage battery? The answer to this is:

First:—Litigation no longer stands in the way of the use of any of the standard types of batteries.

Second:—The application of special types of batteries to special kinds of work has resulted in a vastly improved performance of battery plants in meeting the exigencies of station work. This refers specially to performance of battery in acting as a reservoir for storing the energy represented by the difference between the average and the maximum load, as a regulator of pressure on circuits subject to varying demands and as a transformer utilizing high voltage charging currents and discharging at any lower voltage desired.

Third:—It is generally recognized that plants part steam power and part storage battery are cheaper than an all steam power plant would be for the same work.

Fourth:—The use of batteries in sub-stations frequently permits a saving in conductors between the central and the sub-station.

With regard to litigation it may be said that formerly when one bought a storage battery one contracted the liability to a law-suit at the same time. It is now generally known that this incubus on the storage battery business has been removed. One large company, ably managed, has obtained control of this business by securing to itself the right to manufacture in the United States, storage batteries of all the important types heretofore developed. It has also obtained control of valuable foreign patents as those covering the manufacture of the "chloride accumulator" and the "Tudor" battery.

The field has thus been cleared of litigation and those wishing to use storage batteries can do so without apprehending annoyance or loss in any way. This element of uncertainty was removed simultaneously with the dispelling of the prejudice against storage batteries, caused by their failure in certain applications for which, especially in their undeveloped form, they were notoriously unfit, a circumstance that has been of infinite value in removing the most important obstacle to the use of storage batteries in places where they were especially adapted.

Before taking up the practical side of this subject as covered by the adaptability, performance and economy of storage batteries in central stations it may be interesting to review a few typical battery plants here and abroad which have been installed to perform both regular and special functions. From the "Railway World" of November 12, 1895, the following paragraph is taken:

"The first accumulators used in connection with a railway power station were, so far as the writer can ascertain, those employed in the power plant of the railway lying between Zurich and Hirslanden, Switzerland, an account of which was published in the *Elektrotechnische Zeitschrift* of June 28, 1894. According to report the dynamo delivers current under a constant load, the accumulators being charged or discharged as load on the line is less or greater than the output of the dynamo. In this plant there were automatic means for cutting in and out of end cells to keep the voltage constant. Results showed that by means of the accumulators a saving was effected of 2.2 pounds of coal per hour, amounting to nearly a ton per day, or $2,500 a year. The cost of accumulators, installed complete with accessory apparatus, was $7,400. Allowing for interest and depreciation the battery paid for itself in four years by saving in coal bills alone. The saving was effected by reason of there being no necessity for keeping a second boiler and steam engine in reserve, —and that by this arrangement the power plant ran at its highest efficiency. It was furthermore developed that the first cost of combined steam power and battery plant was less than cost of total steam power plant would have been for the same work.

Two interesting battery applications were recently made abroad in the power plants of the "Douglas-Laxey line" and the "Snaefell Mountain Electric Tramway,"—both in the Isle of Man. In the Douglas-Laxey line it requires a current of 150 amperes at 500 volts to carry a car up the 8½ per cent. grade at a nine-mile rate. Before the battery was connected to the line the cars ran with exceptional smoothness,—the accumulators keeping the voltage steady and eliminating the variations due to sudden starting of cars.

The Mt. Snaefell battery plant consisted of 246 special cells of the chloride accumulator type. At 550 volts, the battery furnished 176 amperes for hours; 112 amperes for 6 hours; 84 amperes for 9 hours; and 72 amperes for 12 hours. The battery was used in precisely the same way as that on the Douglas-Laxey line with the exception that a special use was made of it at seasons of the year showing but little traffic. By agreement the line bound itself to run two cars a day each way every day of the year. As it would not pay to keep the power house in operation just for this load the practice was adopted of charging the battery once a week and allowing it to carry the whole load for the other six days.

Lastly there is the Germantown plant. This battery installation is used to carry the peak of the load and also the minimum load. Speaking of this latter function, Chas. M. Allen, the superintendent has put himself on record as follows:—"In the second place, we do not have sufficient day load to pay us—and it is here the battery comes to our relief. Before we used the battery, the loss on our day circuits was most discouraging. By the use of the battery we have wiped out this loss and can show some profit besides. We now shut down the machinery in the early morning and the battery carries the entire load until nearly dark; then after midnight, while the load is light, but while we must still run our city lights we charge the battery and it is a fact noticed by our engineer, as shown on his reports, that he uses about the same quantity of coal on nights he does not charge the battery as when he does."

We can now take up in a general way the questions of adaptability, performance and economy of the storage battery in a central station considering these in the following order:—

1. Ability of battery to carry peak of load. 2. Economy of battery to carry minimum load. 3. Ability of battery to regulate pressure. 4. Storage batteries in sub-stations.

It is a fact which managers of central stations will testify to that the maximum output of an electric lighting plant is limited to 1½ hours or at most to 4 hours a day. In designing a central station the engineer must choose between several alternatives. First, if he puts in complete steam power plant of most modern type to handle the maximum load, over half of the plant will be idle the greater part of the day, from which it will follow that the profits of lighting will be greatly reduced by large interest charges and heavy stand-over losses in the boilers. Such a plant, besides being very expensive, has no reserve capacity in case of accident. To off-set the question of large first cost it has been proposed to introduce the best type of economical machinery to handle the average output with some less expensive apparatus to take care of the overload. For the latter work, Mr. Perry has proposed gas engines to drive extra dynamos. Such a plant while avoiding the stand-over losses to which a boiler plant is subject, and showing smaller interest charges, is open to the objection that amortization expenses of cheap machinery, not to speak of loss in efficiency, counter-balance the saving in interest. Nor has such a plant any reserve capacity in case of accident. Mr. Perry's suggestion of gas engines would be valuable were it not for the fact that every failure to ignite would appreciably alter the speed of the dynamos, as gas engines cannot maintain their speed when obliged to make two revolutions on a single explosion. As a matter of fact in gas engine plants a storage battery is considered almost absolutely essential as a regulator and as a reserve against break down. Lastly, there is the combination of a steam power plant to handle the average output and a storage battery to take care of the overload. Storage batteries of central station type can be installed for this work for about one-half what a steam power plant would cost,—making a plant half steam power and half storage battery cost only three-quarters what an all steam power plant would for the same work. Mr. C. L. Edgar, general manager of the Boston Edison Illuminating Company, which is the owner of the largest storage battery plant in the world, has put himself on record as to the accuracy of the above figures.

A question that arises here is as to the maintenance cost of such a battery. Generally speaking, it should not exceed that of direct generating machinery. In work of this kind, therefore, the storage battery has undoubted economic value as it suggests the way of designing a central station that will be only moderately expensive and which will be safe-guarded against stoppage arising from accident to the generating machinery.

Coming now to the question of the economy of using storage batteries to carry the minimum load it may be said that opinion is divided on this point. Abroad where the motor load is insignificant the minimum demand for power lasts for half a day. It is thus possible to get along with a single shift of men and something is also saved by drawing the fires, banking the boilers, or other practice when it is not intended to run plant, and it is considered more economical to let the battery take care of the minimum demand than to handle it with the direct minimum machinery. In this country the motor load is very important and the minimum load lasts only from 4 to 6 hours a day. A whole shift of men cannot thus be saved. Experiments have been tried in Boston on a large scale with a view to ascertaining the value of a storage battery in this connection. As yet no definite conclusions have been reached on this point. Undoubtedly there are numerous cases where the minimum load is small and lasts for half a day at least—making it economical to use a battery. The Germantown plant is a case in point where most satisfactory results are obtained by using a battery in such a connection.

One of the most important and valuable functions of a storage battery in a central station is as a regulator of pressure. To anyone who watches the variations in the voltage and amperage of generators running with and without storage batteries, conviction will soon come that the voltage varies perceptibly less when a battery is arranged in parallel with the generator than when it is not. When a shunt wound dynamo, such as are used in central stations, is running alone, any increase in ampere output will be attended by a fall in voltage. When on the other hand a battery is combined with the dynamo, the moment the pressure falls from a large demand for current on the line, the battery begins to discharge and thus augments the output of the dynamo. In other words the battery acts as a reservoir; when the load on

the line is small the battery is charged; when the load becomes heavy the battery begins to discharge and in so doing performs a doubly valuable function. In the first place it saves the generating machinery from strain, and, secondly, by keeping the pressure constant, makes possible a much higher efficiency both in the station and on the line. Mr. Edgar has said that if a steam plant and a battery plant were on a par in all other respects he would personally feel very much inclined to install a battery plant for the above reason alone.

Lastly we came to the question of the use of storage batteries in sub-stations. Just imagine a city which has spread out irregularly At some distance from the central station it may happen that the population is large and that considerable current will be required to furnish adequate light. If the situation is such that it is cheaper to furnish light from the central station than to operate a small power plant as a sub-station the former will be done. The consequence of this will be shown in very heavy losses in the line owing to large currents transmitted, and secondly there will be very heavy interest charges for very large conductors. If on the other hand a storage battery sub-station were located in the centre of this suburb the following economies would be gained. In the first place much smaller conductors would be employed, resulting in diminished interest charges, and secondly a high tension current would be used in transmission by which losses on the line would be lessened. These economies are brought about by the ability of the battery to act as a "transformer." In other words the battery may be charged in series with a high tension current and discharged in multiple bringing the pressure at the sub-station down to requirements.

On the other hand a battery may be charged in multiple and discharged in series by which it will be possible to get along with one dynamo instead of two or more in series. Owing to the flexibility of storage batteries they are splendidly adapted to working on a three-wire or a five-wire system.

There is one point that has not, thus far, been touched upon, namely, the coal consumption in a station consisting of both generators and batteries. The use of storage batteries is sometimes objected to on the ground that there is a loss of fifteen to twenty per cent. of the watts generated while the battery is being charged. Perhaps we can do no better than by quoting Mr. Edgar again. "The watts lost," says Mr. Edgar, "by the inefficiency of the battery are made up more than four-fold by the better economy of the steam plant. We have taken typical winter days and figured out exactly the cost of running our system with the battery and without, and have proved that the actual coal consumed with the battery is a material amount less than without it."

To recapitulate, storage batteries are valuable in central stations on account of the three-fold function they perform, as reservoirs of energy, regulators of pressure and transformers of high to low or low to high tension currents. In performing these functions they make possible lower first cost in main central station and lower first cost for conductors between this and the sub-stations where batteries may be installed. They are, further, valuable in saving the power and generating machinery from strain and in effecting economy by introducing the factor of high efficiency in the station and on the line.

LEGAL NOTES.

DATA ON STREET RAILWAY CONSTRUCTION IN NEW YORK.

THE action brought by the Southern Boulevard Railroad against the People's Traction Company and the North New York City Traction Company, and Comptroller Fitch to restrain the latter from awarding to the first defendants a franchise for surface roads between the Harlem and the Bronx Rivers, it being alleged that the bidding for the franchise, which ran up to nearly 7,000 per cent. of the gross receipts, was farcical, was put on trial last week in Part III. of the Special Term of the Supreme Court. It will be remembered that the bidding was suspended by a preliminary injunction which Justice Beach continued until trial.

Its chief interest lay in the important evidence of H. H. Vreeland, President of the Metropolitan Railway Company, who was called as an expert, and gave statistical evidence concerning the cost of construction, of equipment and of operation for surface roads operated by electricity.

He said that the cost of construction per mile varies from $10,000 to $35,000 according to local conditions, and the requirements of municipal authorities. For example the paving required here by the city costs $6,000 a mile. The average cost of a trolley car including motors up to the moving of the car is $2,000. The average cost per car-mile of operating an overhead trolley system is 14 cents in New York, 18 in Massachusetts, and 15 in New Jersey.

The per cent. of operating expense to receipts varies from 55 to 60. The per cent. depends on the density of population and whether the riders are through passengers or short-trippers. The witness said he was not familiar enough with local conditions in the towns of Mamaroneck, New Rochelle, Rye and Pelham to give an estimate of the rates of operating expenses to receipts.

The Lenox Avenue line in this city, was originally built for a cable and then changed into an underground trolley road by the General Electric Co. The One Hundred and Sixteenth Street cross-town line, built originally for an underground trolley, cost $45,000 per mile of single track, which included considerable paving. In a suburban section where paving need not be considered a similar track could be laid for $30,000 a mile. A cable road would cost three times as much, but the legitimate place for a cable line is a straight track. The cost of constructing a storage-battery line would be the same as for a trolley less the cost of overhead construction. To operate by storage battery on a horse-car track would cost a third more because of the extra weight of the cars and their rocking. To build a horse-car track costs $20,000 a mile. An overhead trolley costs 60 per cent. of gross receipts, compared with 75 per cent. by horse power. The cost of equipping a road twenty miles long in the Twenty-third and Twenty-fourth Wards would be $2,000 a car, and a power-house would cost according to the number of cars to be operated—$2,000 a car. To operate forty cars would require a power-house costing $80,000.

WESTERN ELECTRIC CO. vs. NAT. TELEPHONE MFG. CO.—RULING ON DEMURRERS.

In the United States circuit court, Boston, on Jan. 13, Judge Colt heard arguments of counsel on the demurrer filed by the defendants in the case of the Western Electric Company against the National Telephone Manufacturing Company et al.

The suit is a bill in equity brought to restrain the defendant telephone manufacturing company and its officers from making, selling or using certain call boxes or telephone exchange apparatus for which the plaintiff claims to own patents.

The demurrer of the defendant company was on the claim that the plaintiff was not entitled to maintain its bill because it was not brought in the proper circuit as against it. The demurrer of the officers of the defendant company urged this claim as a ground for the action, together with the further claim that the plaintiff's bill alleges no joint infringement between defendant corporation and them, and also the claim that the bill stated no ground for equitable relief.

The court sustained the demurrer filed by the defendant corporation, and overruled the demurrer filed by the officers.

F. P. Fish and Barton & Brown for complainant; E. P. Payson for defendant.

HOW CITIES CAN SAVE MONEY.

No intelligent business man doubts, probably, that the entire volume of our city's business, for instance, could be done much better than it now is for one-half of what it costs if it were done on the principles that govern in the carrying on of private business. The clerical work in the city hall and in the various departments would show just as great a disparity against the public if compared with similar work done for private parties, as is shown in the comparison already alluded to between the cost of the public's janitor service and what private parties pay for similar service. Parties could easily be found to enter into contract—and give bonds for faithful performance—to do all the municipal work of Detroit, the paving, sewering, lighting, water supply, etc., for half what the city pays to-day. And they could make a handsome profit out of the business even then.—*Detroit Free Press.*

BROOKLYN BRIDGE AS A "MUNICIPAL PLANT."

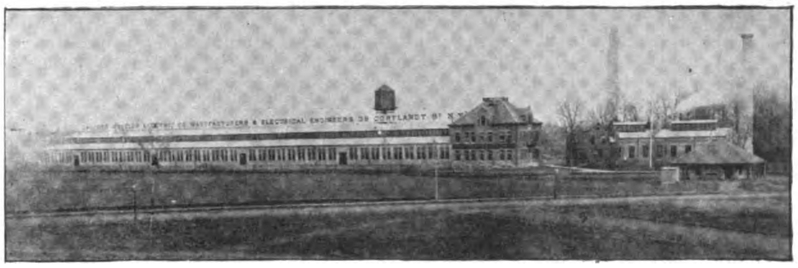
Legislative investigations have come, and legislative investigations have gone, and not one has yet touched upon the most magnificent piece of public mismanagement that the New York public was ever cursed with. I mean the great Brooklyn Bridge. It has often been said that the New York public is the most good. natured, long-suffering and patient of any city in the world. Visitors from other cities and foreign travellers marvel at this. It certainly must be true. If it were not so, I am perfectly sure that the stupid, ignorant, impracticable, thickheaded and incompetent management of the Brooklyn Bridge would have been kicked out of office long, long ago. If you have never attempted to cross the bridge during the so-called "rush hours," you would never believe that such a shocking condition of affairs could possibly be permitted in a civilized community. I can only think of one scene which parallels this—a panic-stricken crowd which pushes madly out of a theatre when somebody has started the cry of fire. I wish the readers of *The World* who read this paragraph would come down to the New York entrance of the bridge any afternoon between 6 and 7 o'clock, and then and there determine in the heat of righteous indignation what ought to be done to make this magnificent highway between New York and Brooklyn what it ought to be, and in the hands of intelligent men soon would be.—*New York World.*

Society and Club Notes.

VISIT OF THE AM. SOC. OF CIVIL ENGINEERS TO THE NEW CROCKER-WHEELER FACTORY.

In connection with the annual meeting in New York City of the American Society of Civil Engineers, a very interesting special trip was made on the morning of Jan. 15 to the rebuilt factory of the Crocker-Wheeler Electric Co. at Ampere, N. J. A special train of three cars was run from New York for the purpose, and it was crowded with members and their friends, about 50 ladies being also in the party. The honors of the occasion were done by Dr. S. S. Wheeler, president, and Prof. F. B. Crocker, assisted by several members of their engineering, office and factory staff; and a most instructive morning was spent.

The entire plant is new, having been rebuilt this summer on



General View of Crocker-Wheeler Electric Co.'s Shops, Ampere, N. J.

the site of the old works occupied by this company, which were formerly the works of the Spiral Weld Tube Company. The new buildings are of the modern slow-burning mill construction, and have been erected practically in accordance with the plans of the New England Mutual Insurance Companies.

The principal engineering feature is the electrical power transmission system which is employed throughout. All of the machinery is operated by individual motors built into each machine, or by separate motors, each driving a single length of shafting, which in turn drives as many of the old-style machines as can be conveniently belted to it. The result is, first, that all power used in connection with these machines is stopped whenever the machine is out of use, and second, that the works are free from belting, leaving them remarkably light and clear for handling material. In addition to the remarkable reduction in power required for operating the plant, this method of driving gives a shop system of great flexibility. This was well illustrated during the past summer when many of the company's machines were operated in their original positions in the ruins of the old works which were burned, under temporary covers, by means of temporary wires run to the motors built in them. The machines were afterward from time to time moved from one position to another as the work on the new buildings required, being kept, however, in continuous operation day and night. By this means the company turned out 20 per cent. more product this year than ever before in its history, in spite of the fact that for three months the entire plant was in ruins. A curious spectacular illustration of the flexibility of electric power was given by hoisting into the air by the electric crane a large electric lathe, which went on with its work, the long spiral of cutting from which curled off slowly to the floor all the time.

The lighting and power for the plant are supplied by a 150 horse-power Corliss engine driving an 80 kilowatt dynamo in the detached power-house. There is also an auxiliary plant. The current is conducted from the power-house by cables through an underground tunnel, which also carries the heating pipe and the cables for experimental work through the cellar of the office building, thence rising from a manhole under the floor of the main shop and running along under the roof by ordinary trolley line insulators to about the centre of the shop, where they terminate on suitable slate panels. From these branch out four sets of wires carried in a similar manner along the roof trusses and extending through and feeding the four quarters of the main building. By this arrangement the supply of power for either section of the shop can be readily discontinued by a small switch.

From the switchboard run also the circuits for supplying the other buildings. The branch connections from the main circuits are carried down the inside of the cast-iron columns of the building to a point about 6 inches below the surface of the floor; thence they are carried along through small wooden troughs, which were laid for this purpose in the concrete, straight across the shop close to the bases of each pair of columns, or 10 feet apart. The wires are brought up from the troughs through the floor wherever connections are desired, through 1-inch holes bored through the flooring. The wires pass into and out of the centres of the columns through small handholes cast in them near the top and bottom.

The king posts of the roof trusses are extended upward so as to furnish posts for the roof sign. The main building is 100 feet wide and 450 feet long, the office building adding another 50 feet to the length.

In the construction of the buildings it was decided to use a floor heavy enough for the foundations of any machinery it was desired to put down at any part, and which would also permit the carrying of heavy loads on roller trucks, rather than to introduce handcar or industrial railroad tracks, since this would greatly cut up the floor, and could not be arranged to reach every part and avoid interference of two cars on one track.

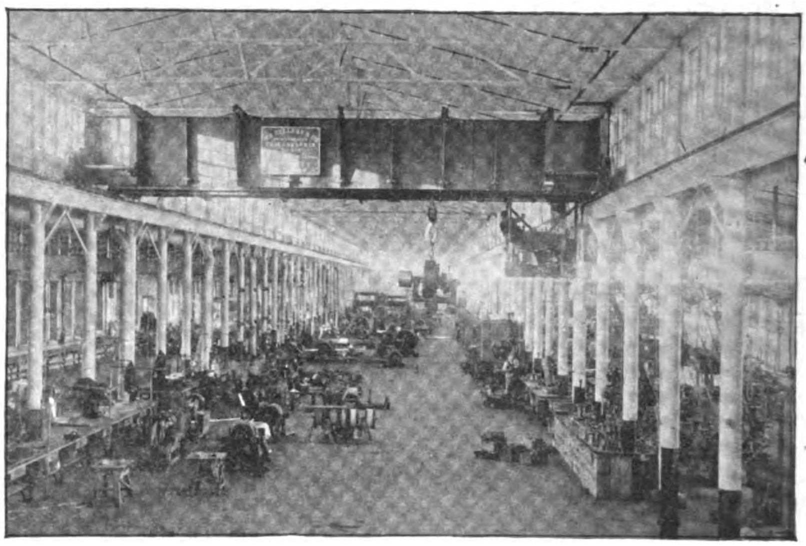
The beautiful office building is designed with special reference to facilitating the work of the engineering department and the management of the company. The general offices and the office of the chief engineer and assistants are on the main floor, with connections directly to the floor of the shop. The workmen's entrance, also on this floor, is so arranged as to make the men pass through the bookkeepers' department. The second floor contains the drafting department, blue-print and photographers' rooms, and the toilet and locker rooms. The third floor will be for assistants and storage. One half of the basement is arranged for a laboratory for such experimental work as it is desired to carry on without disturbing the shop; the other half is for bicycles. Up through all of the floors extends a fireproof vault about 10 feet square, with arched brick floors and air spaces on all sides, for the reception of the records of each department.

The visit closed with a very creditable fire drill, using water from the tank supplied from the company's electrically driven artesian well.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 102d meeting of the Institute will be held at 12 West 31st Street, on Wednesday, January 22d, at 8 o'clock P. M. Mr. Frank J. Sprague will present a paper on "Electric Elevators, Their Uses and Advantages," embodying specific descriptions of various types which will be shown by lantern slides.

The meeting of the western members will be held on Wednesday evening, January 29th (one week later), at the Armour Institute, 33d St. and Armour Ave., Chicago.



Crocker-Wheeler Main Shop, Looking North.

ELECTRICAL SECTION OF THE AMERICAN INSTITUTE.

The above section held a regular meeting at the Institute headquarters on Jan. 17, when a paper on the subject of "Transformers" was read by Dr. M. I. Pupin, of Columbia College. The lecture was extremely interesting and was illustrated by many

brilliant experiments, dealing with lines of investigation on this important subject.

FOURTH ANNUAL CONVENTION NORTHWESTERN ASSOCIATION.

THE Fourth Annual Convention of the Northwestern Electrical Association began at the Hotel Pfister, Milwaukee, on Wednesday, January 15th, and was continued for the two following days.

The convention was opened in the forenoon by PRESIDENT GEORGE GRIMM. After making some feeling remarks as to the loss which the Association had sustained by the death of their late President, Mr. Henry C. Thom, whom he had succeeded, he entered into the business of the day. He said that he regretted to have to state that the Association was not in as strong a position financially, as was desirable. The president further added in this respect, that owing to the absence of the Secretary, Mr. Goltz, who is now in Europe, he had become very familiar with the business affairs of the Association. Without any extraordinary expenditures, he found that each succeeding report of the Secretary showed a deficit in the treasury. He believed that a plan could be easily devised which would again place the Association on a sound financial basis, and to help to attain this end he earnestly asked the members to be prompt in the payment of their dues.

Another matter which he said required the attention of the members was that the Association should distinctly define the extent to which the officers and the Association will go in furthering proper legislation relating to electrical matters.

THE SECRETARY'S report showed that the Association had grown considerably within the past year.

The election of officers for the ensuing year was taken up at the afternoon session, the following being elected: President, Pliny Norcross, Janesville, Wis.; first vice-president, Chas. D. Wyman, Milwaukee; second vice-president, H. C. Higgins, Marinette; secretary, Thos. P. Mercein, Milwaukee; treasurer, John Schuette, Manitowoc. Mr. Mercein takes the place of Mr. Wm. Goltz, who is now abroad.

Two papers were read during the afternoon. The first was by W. J. Buckley on "Modern Apparatus and Existing Conditions."[1] The paper by A. V. Abbott on "Economic Expression for Fuel Value," which was down on the programme, was not read, so Fred De Land followed with his very interesting paper on the "Upbuilding of a Small Town."[2]

In the evening a large number of the members and delegates visited the Bijou Theatre and witnessed the performance of the "Devil's Auction."

On the second day the session was taken up with the reading of papers, the most interesting being entitled "Some Facts About Acetylene Gas," by J. C. McMynn, and also a paper by E. R. Cunningham entitled, "Power Transmission Plants."

During the day a telegram was received from Mr. Pliny Norcross, who had been elected president of the Association, in which he declined to accept the office.

Owing to the absence of Mr. Norcross, Mr. C. D. Wyman, who was elected first vice-president, presided at the meeting.

In the evening the Association held its annual banquet, about one hundred people being present. After the dinner was over, a number of very lively and interesting speeches were made, amongst those who spoke being Thos. R. Mercein, H. G. Underwood, Geo. Cutter, R. C. Spencer, C. D. Wyman, F. DeLand, John Schuette, Jas. Wolff, E. H. Bottum, I. P. Lord.

The banquet was considered by all those who attended it to be one of the most successful that had been held.

At the third session the matter of electing a president to take the place of Mr. Pliny Norcross was taken up and Mr. W. B. Baker, Waupaca, Wis., was chosen. After some unfinished matters had been disposed of, the convention terminated.

The trip which it was intended should be made to view the fine new City Hall and also the Cudahy Packing Company's plant was abandoned, and a few of those who had attended made a visit to the engine works of Messrs. Allis & Co.

EXHIBITS AND CONVENTION NOTES.

THE CENTRAL ELECTRIC CO., Chicago, had their interests looked after by their representative, Mr. H. M. Latimer.

THE BRYANT ELECTRIC CO. of Bridgeport, Conn., were represented by Mr. Thos. G. Grier, of Grier Bros., Western Managers for the above Company.

THE AMERICAN CIRCULAR LOOM CO. were represented by their able Western agents Messrs. H. H. Brooks and A. D. Chandler, who kept well in line and with their usual energy boomed the conduit.

THE ELECTRIC APPLIANCE CO. had their energetic representative, Mr. W. W. Low, on hand. He is always to the fore at conventions, but unfortunately owing to pressure of business and other matters he had to tear himself away before the finish, which was consequently very tame.

1. See page 90. 2. See page 101.

MR. G. W. STURGES was on hand for the Joliet Steel Co.

THE HARTLEY ELECTRICAL WORKS of Chicago were represented by Mr. B. Hartley.

THE CUTLER-HAMMER MFG. CO. had a good representative present in Mr. H. H. Cutler.

MR. GEORGE CUTTER stood for himself as usual and represented his constituency very ably.

MR. C. W. WOODWARD was in the field for the Electric Storage Battery Co. for whom he is the Western manager.

THE COLUMBIA LAMP CO. were represented by their Chicago agent, Mr. J. M. Hill.

MR. E. DICKIE was around for the American Carbon Co., Nobleville, Ind.

MR. L. W. COLLINS, a well known Convention figure, was all alive for business for the electrical specialties carried by Lee & Collins, Chicago.

MR. ALBERT SMITH, of Keelyn and Smith, Milwaukee, was a frequent visitor to the Pfister during the Convention.

THE WESTERN ELECTRIC CO., Chicago, had their business well attended to by their representative, Mr. John W. Ebert.

CHICAGO GENERAL FIXTURE CO. were represented by Mr. C. O. Baker.

WESTINGHOUSE, CHURCH, KERR AND CO. sent Mr. Jerome B. Wilkinson, of their Chicago office, to represent them.

MR. THOS. RACINE, Milwaukee Auxiliary Fire Alarm Co., was to the fore at the Convention all the week.

JULIUS ANDRAE & SONS of Milwaukee were ably represented by Mr. Herman Andrae.

THE WISCONSIN ELEC. CONS. CO. were represented by Mr. F. Morawetz.

WILSON, CLARK CO. of Chicago were represented by their president Mr. J. McNeill Wilson and J. H. Clark, Jr.

LANGSTADT & CROSSWELL, of Appleton, Wis., were represented by Mr. M. H. Crosswell.

WARREN WEBSTER & CO. were represented by Mr. W. D. Pickels.

THE WESTINGHOUSE GLASS FACTORY was represented by its Chicago Agent, Mr. J. H. Reid.

THE ELECTRICAL PRESS was represented by F. L. Perry, W. P. Sullivan, A. V. Abbott, F. De Land, W. A. Remington, J. V. S. Church, L. L. Summers.

MR. J. M. ATKINSON, Chicago, representative of the Forest City Electric Co., Cleveland, was around, bright and energetic as usual.

MR. E. L. CLARK, of the Valentine Clark Co., Chicago, materialized from the bleak Northwest on the second afternoon of the Convention.

MR. JOHN T. MCROY, Chicago, showed his new underground shale conduit, his sample being a 4 duct of 3¼ inches diam. He explained to numerous callers the virtues of this recent invention.

THE SUNBEAM INCANDESCENT LAMP CO., Chicago, had the Messrs. F. S. Terry and A. S. Terry around with their habitual alertness, extolling the longevity and brilliancy of the Sunbeams.

THE ROYAL ELECTRIC CO., Peoria, Ill., showed one of their new transformers with removable coils for which they claim many sterling qualities. Mr. G. G. Luthy was constantly on the scene in their behalf.

THE ADAMS-BAGNALL ELECTRIC CO., Cleveland, were represented by Mr. L. H. Rogers, who found the days and nights altogether too short to allow him to tell everybody who wanted to know, all about the merits of their new lamps and specialties.

THE FORT WAYNE ELECTRIC CORPORATION provided a very substantial lunch to which all visitors were heartily welcomed. W. J. Buckley, C. E. Wilson and J. C. Murphy of the Chicago office looked after the wants of their friends in a very able manner.

THE WIRE TRADE was largely represented, Grimshaw and Raven Core, Safety, Simplex, American Electrical Works, Roeblings, Crefeld, Washburn & Moen, being all on hand with their energetic representatives, Messrs. Wolff, Austin, Hixon, Donahoe, Gordon, Lasell and Gill who were all activity for their various interests.

THE OSBURN ELECTRIC CO., Chicago, had on view their new conduit suitable for buildings; this conduit is made of galvanized steel tubing with 6-inch lengths of porcelain inside, for which they claim that it is absolutely insulating and fire proof. They also had a line of the Oscarow imported woven wire brushes. Mr. Roy Osburn and his assistant Mr. Wm. Gallagher were in charge.

THE PEOPLES ELECTRIC CO. of Madison, Wis., were represented by their Pres. Mr. L. W. Burch, who showed a very neat line of the electric light, street railway, and household supplies carried by this new and enterprising concern. They also had on exhibition a Paiste arc lamp focusser, Adams-Bagnall arc lamps, Standard telephones, and a very interesting lot of photographs of the electrical machinery manufactured by the Northern Electrical Mfg. Co., for whom they also are selling agents.

THE GENERAL ELECTRIC CO. had on exhibition two of the T.-H. 93 arc lamps suitable for direct or alternating incandescent circuits. They also had on show some switches and other electrical specialties, and distributed their Moonlight Schedule Calendars for 1896 to their visitors. Messrs. F. N. Boyer, A. C. Bunce, M. C. Wheaton, and W. S. Howell were on hand to greet friends.

The subjoined list includes the names not given in the Exhibit Notes:—A. V. Abbott, J. Angel, B. J. Arnold, A. O. Baker, R. M. Bashford, J. I. Beggs, H. F. Boggis, F. V. Boyer, R. E. Brown, A. C. Bunce, Carroll Collins, G. L. Cole, S. G. Coleman, G. M. Conway, Wallace P. Cooke, F. A. Copeland, Chas. Cuno, E. L. Debell, G. A. Farwell, W. W. Fisher, T. J. Fleming, Geo. Grimm, T. F. Grover, J. H. Harding, A. W. Hawley, H. C. Higgins, M. H. Hussey, J. H. Jones, P. H. Kolst, Edw. Lasell, Luke Lilly, I. P. Lord, G. S. McLaren, J. D. McLeod, E. G. Mullen, Geo. M. Newton, C. C. Paige, T. A. Pamperin, Frank A. Pigeon, O. M. Rau, Carl Richer, D. E. Roberts, C. H. Ruggles, John Schuette, Geo. A. Searing, A. Smith, W. C. Smith, J. S. Stephen, W. H. Thorp, F. Werner, J. F. Willey, O. B. Williams, C. D. Wyman.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JAN. 14, 1896.

Alarms and Signals:—

Messenger Call System for Buildings, H. Denver, Springfield, Mass., 552,897. Filed June 24, 1893.

Consists in the arrangement, with the call box conveniently located for two or more occupants, of one or more indicators which may be set to indicate or point out the room from which the messenger call was sent out.

Electric Bell, O. B. Sterling, New York, 552,983. Filed Sept. 3, 1895.

Conductors, Conduits and Insulators:—

Clip for Supporting Electric Cables, R. H. Lewis, Providence, R. I., 553,194. Filed Oct. 30, 1895.

Dynamos and Motors:—

Electric Motor, D. C. Jackson and C. M. Conradson, Madison, Wis., 552,961. Filed July 26, 1895.

Various novel features of construction.

Electric Furnace and Products:—

Manufacture of Carbide of Calcium, W. C. Clarke, New York, 552,890. Filed Aug. 24, 1895.

Consists in building up the furnace wall as the formation of the carbide progresses, adding fresh charges of the material to be treated as the wall is built up and keeping the lower end of the upper electrode at all times near the upper edge of the furnace wall.

Electrolytic Processes:—

Process of and Apparatus for Making Carbonates of Soda, T. Craney, Bay City, Mich., 552,895. Filed May 15, 1894.

Object is to make mono- and bi-carbonate of soda on a commercial scale by the electrolysis of salt brine.

Process of and Apparatus for Manufacture of Sodium Bicarbonate, T. Craney, Bay City, Mich., 552,955. Filed May 11, 1894.

Details of apparatus relating to the commercial manufacture of bicarbonate of soda from salt brine.

Process for Producing Cuprous Oxides, C. Hoepfner, Giessen, Germany, 552,960. Filed Oct. 7, 1893.

Consists in leaching cupriferous materials with a cupric chloride solution containing a solvent of cuprous chloride whereby a solution containing cuprous chloride is obtained, reconverting the cuprous chloride, and converting the cuprous chloride in the other portion of the solution into cuprous oxide by means of a suitable reagent.

Lamps and Appurtenances:—

Electric Arc Lamp, L. G. Nilson, Sioux City, Iowa, 552,967. Filed July 25, 1893.

Details of construction.

Electric Arc Lamp, F. J. Borland, Leeds, Eng., 552,982. Filed Aug. 17, 1894.

Specially adapted for projecting purposes.

Electric Lamp Support, J. Buckner, Boston, Mass., 553,220. Filed June 10, 1895.

Has for its object to provide an improved construction whereby the lamp may be insulated from the metal post. Also to protect the lamp trimmer from injury.

Miscellaneous:—

Electric Releasing Device, S. H. Reynolds, San Jose, Cal., 552,924. Filed Mch. 13, 1895.

Improvements in that class of devices which are adapted for use in stables, engine houses and the like, for releasing horses in case of fire.

Automatic Lighting or Extinguishing Apparatus, S. C. Stickle, New York, N. Y., 553,198. Filed May 10, 1895.

The circuit is closed by a clock at the proper intervals.

Automatic Electric Releasing Device, J. W. Chute, San Jose, Cal., 552,954. Filed Apl. 16, 1895.

An automatically operating release and resetting device which is applicable to open gates or doors, to release any mechanism, to disengage horses from their fastenings, etc.

Railways and Appliances:—

Motor-Truck, L. Warfield, Detroit, Mich., 552,922. Filed Nov. 18, 1891.

Secures the gear on the axle, so that while turning with it it is free to move longitudinally along it.

Street Indicator, C. Eby, Rocky River, Ohio, 553,058. Filed Aug. 28, 1895.

A belt which carries the names of the street, is operated by power transmitted from the trolley wire.

Trolley Cut-Out, T. Fletcher, Idlewild, Tex., 553,061. Filed Mch. 28, 1895.

A hanger made in sections coupled together and adapted to automatically uncouple as soon as the live wires break between adjacent hangers.

Bonding Device for Electric Railways, W. Brown, Camden, N. J., 553,099. Filed May 25, 1895.

The bond is expanded into the rail by a taper screw.

Electric Railway, T. F. O'Connor, New York, 553,176. Filed Apl. 2, 1894.

The motors are fed by separate conductors, each conductor having one end connected to and moving with the vehicle fed by it and the other end connected with the source of power and stationary as respects the movement of the vehicle, the length of the conductor being sufficient to permit the vehicle to move the desired distance from the stationary end of the conductor.

Switches, Cut-Outs, etc.:—

Electric Circuit Connector, T. F. Nevins, Brooklyn, N. Y., 553,014. Filed May 16, 1895.

Adapted for use with portable electric lamps, small sized motors, etc.

Telegraphs:—

Automatic Closing Telegraphic Key, J. A. Coleman, Perry Station, Canada 553,106. Filed Nov. 13, 1895.

An attachment whereby the telegraphic key will of itself immediately close the circuit after the operator has removed his fingers from the finger button.

Telephones:—

Telephonic Apparatus, C. J. Schwarze, Adrian, Mich., 552,972. Filed April 22, 1895.

A combined magneto calling generator and transmitter.

Telephone Circuit, E. Slade, Newton, and J. S. Stone, Boston, Mass., 553,179. Filed July 12, 1895.

Device for preventing a "click" in the receiver in centralized battery systems.

MARRIED.

ANGIER-GILL.

At Harvard Congregational Church, Dorchester, Mass., on Thursday forenoon, January 16th, Mr. G. M. Angier, of Boston, was married to Miss Emma J. Gill, of Dorchester, and the happy couple immediately thereafter departed for a few weeks' honeymoon in the South. Mr. Angier has been well known in the electrical business for years, all over the United States, having travelled in every part of this country. For some years he made Chicago his headquarters, but of late he has been settled in Boston, representing the interests of the Mather Co. and later the Eddy Electric Mfg. Co. of Windsor. Mr. Angier is deservedly a popular man, and there are a very few who can count up so many warm friends as he has made in the past few years, by uniform courtesy, interesting personality, and by an ever-flowing fund of good humor and kindly good nature. All his friends will be glad to hear of his marriage and to wish him God-speed, and have evinced their warm regard by a large number of beautiful presents received at the house of the bride. The marriage was a very pretty and simple church wedding, the bride being accompanied by only one maid of honor, Miss Gertrude C. Bent, of Boston. Mr. and Mrs. Angier will be at home to their friends early in the spring, in their residence at Wahan, which Mr. Angier has recently built; and will reside temporarily at the Hollis in Newton, Mass.

REPORTS OF COMPANIES.

STANDARD ELECTRIC CLOSING UP.

The Standard Electric Company, whose factory is at 818 South Canal street, Chicago, and whose office is in the Home Insurance Building, that city, has made an assignment in the county court. The assignee is George M. Stone, of the law firm of Rich & Stone. A statement was filed as to the assets of the company, which are placed at $25,000, but the liabilities were not given. The company manufactures dynamos, electric lights and other electric supplies, and its president is A. G. Spalding. The other officers are E. E. Crepin, treasurer; D. P. Berry, manager, and George A. Mayo, superintendent.

Assignee Stone said the liabilities of the company are less than the assets, and all the creditors of the company will be paid in full. He said the company has not been making money of late, and the object of the assignment was to wind up the business, pay off the debts and close up.

THE JENNEY ELECTRIC MOTOR CO.

Mr. A. K. Hollowell has purchased a half-interest in the Jenney Electric Motor Company of Indianapolis and will at once take control of the financial and general business management of the company. Mr. Jenney will have charge of the manufacturing department. Mr. Hollowell has been the treasurer and financial

manager of Nordyke & Marmon for twenty years. For ten years he was interested in the electric department of the Jenney company's business. The Jenney company has recently moved into a new place, east of the city, at the Pan-Handle and Belt railroad crossing. Seventy-five men are employed, and room for more is already needed. The works are in operation day and night, and the company is running to its full capacity to fill current orders. An addition to the building is contemplated. The company manufactures motors and electrical apparatus, and has been making a specialty of elevator motors.

MAGUIRE & BAUCUS, LTD.

The company of Maguire & Baucus, Limited, has just been incorporated with a paid up capital of $250,000. The concern is formed largely for the purpose of export business in electrical apparatus, specialties, etc., and has connections throughout Europe and South America. Messrs. Maguire & Baucus in marketing Edison's latest invention, the Kinetoscope, all over the world, outside of the United States, have been very successful; and they are well known in electrical circles. The officers of the Company are Jos. D. Baucus, President; Frank Z. Maguire, Vice-President and General Manager; Walter B. Howe, Treasurer, and William M. Paxton, Jr., Secretary. The Company is located at 44 Pine Street, New York, and Dashwood House, No. 9 New Broad Street, London.

AM. RY. ELEC. LT. CO. ATTACHED.

Lawyer J. Campbell Thompson has obtained from Justice Pryor in the New York State Supreme Court an attachment against the American Railway Electric Light Company in an action brought by Alexander Tait on a claim for nearly $500 for unpaid notes of the company, and for rent of a machine shop in Brooklyn used by the company. A copy of the attachment was served on Assistant Manager M. T. Wilbur, of the Western Union Telegraph Company, who is trustee of the company's stock. Ex-Gov. Alonzo Cornell was once president of the company, and is interested in it.

LETTERS TO THE EDITOR.

FROM A LEADING STATION BUILDER.

Please accept my congratulations on the very excellent article appearing in your issue of January 8, on the Edison Central Stations in New York City. I can appreciate the amount of labor that is expended in preparing an article of this kind, and I am sure that it is worthy of most cordial endorsements.

J. H. VAIL.

NEW YORK CITY, Jan. 16, 1896.

ELECTRIC PHOTOGRAPHY WITHOUT LIGHT.

Further dispatches from London of Jan. 18, in regard to Prof. Rontgen's photographic work say:—The marvels of Prof. Rontgen's new photography are even greater than those which I have described in recent despatches. All the Professor's experiments have been successfully repeated in London this week, and many of them were shown at the meeting of the Camera Club on Thursday. It proves that the strange medium which produces images of hidden objects on a photograph plate is not light at all. It is equally incorrect to describe it as electricity. It is some force or influence produced by Crookes' tube when excited in a peculiar manner, but it is not the visible light or glow which comes from the tube. That visible light has the same qualities as an ordinary light. The invisible new medium has not the same qualities. For instance, it will not penetrate clear glass. It will penetrate ground glass, though more feebly than wood and other organic matter. Aluminum is far more transparent than glass. Even copper is less opaque than glass.

Mr. Swinton, the well-known electrical engineer, showed a large collection of these strange photographs which had been taken to the Camera Club. He employed a half horse-power electric current, and passing it through an induction coil, loaded ten Leyden jars. The discharge from them was passed through a second induction coil by a secondary system by which Crookes' tube was excited. He said that he had only succeeded in this way, and had failed with Crookes' tubes excited by an ordinary induction coil.

He showed pictures of the skeleton of a living human hand, a purse containing coins in which only the coins and the metal clasp of the purse were reproduced, and other objects.

The method of procedure was simply to place the object to be photographed between Crookes' tube and the usual wooden case containing the sensitive plate in which the negative is placed when carried to and from the camera. The slide is not removed, and an exposure of from four to twenty minutes is required.

Another cable dispatch of Jan. 19 says:—Emperor William had Prof. Rontgen to rush from Wurzburg to Potsdam to give an illustrated lecture to the royal family on his alleged discovery of how to photograph the invisible, and bestowed on him the Order of the Crown, the same second-class decoration that poor Koch got; but already it is found that this discovery was not only made by a Prague professor in 1885, who got an admirable photograph of Mont Blanc at dark midnight by the use of cathodic rays, but that a full report of the achievement was made to the Austrian Academy of Sciences in 1885.

An item in the *New York Sun* recalls the fact that Mr. Edison some time ago produced a plate which would record in the dark the fact that it had been near a warm body. Mr. Tesla has also called attention to the actinic qualities of the electric rays with which he has produced photographs by "phosphorescence."

PERSONAL.

THE TENDER MERCIES OF THE CZAR.

A special dispatch from Pittsburgh of Jan. 10, says:—In May last Alex. Boroday, a Russian by birth, an electrician in the employ of the Westinghouse Electric Company, was sent to Russia in connection with the establishment of trolley railway plants in that country. He had been a political offender before coming to America six years ago, but the Czar's amnesty proclamation made him feel safe in going back. A letter from Kiev to another Russian resident here states that Boroday was arrested there, and that nothing can be learned of his whereabouts. It is supposed, the letter adds, that he has been exiled to Siberia. The officials of the Westinghouse Company have written to Secretary of State Olney, invoking the aid of the Government in behalf of the missing man, who is a naturalized citizen of the United States.

MR. GEORGE COCKINS, formerly of the Waterbury, Conn., Electric Light and Traction Co. as assistant manager has succeeded Mr. O. F. Strunz as general superintendent of the Bristol and Plainville Tramway Co.

ELECTRICITY AND VEGETATION.

Two important Papers, says *Nature*, have recently been published on the effect of the electric light and of electricity on vegetation. The first is by M. Bonnier in the *Revue Générale de Botanique*. He states that a continuous electric light promotes the formation of chlorophyll, and brings about, at the same time, a simpler anatomical structure of the leaves. Under a continuous electric light the distribution of the chlorophyll in the tissues is more extended than in ordinary daylight; chlorophyll grains make their appearance in the cortex as far as the endoderm, and even in the medullary rays and the pith. The palisade tissue of the leaf is reduced, or entirely disappears, and the epidermal cell walls are thinner. The bark is less developed, and the various tissues of the stem are less differentiated. When the electric light is discontinuous, as, for example, when turned on 12 hours out of the 24, the effect on vegetation is intermediate between that of normal sunlight and that of a continuous electric light. Alpine plants cultivated under a continuous electric light exhibit points of structure identical with those of Arctic plants, which are exposed to almost continuous sunlight in the summer. The other Paper is by Prof. A. Aloi in the *Bulletino* of the Italian Botanical Society. He adduces evidence in favor of his view that both terrestrial and atmospheric electricity exercise a favorable influence on the germination of seeds and on the growth of plants, and predicts that the employment of electricity will be a most important factor in the agriculture of the future.

THE VOLATILIZATION OF CARBON.

M. Moissan finds that when carbon is volatilized in his electric furnace it evaporates without melting, and that when the vapor condenses it always deposits as graphite. He also finds that aluminum carbide may be made, mixed with metallic aluminum, by the direct reduction of alumina with carbon in the electric furnace, and that when this carbide is treated with water it evolves chiefly marsh gas or methane (CH_4), not acetylene. This promises to furnish a new starting point for the methyl compounds and derivatives, which have hitherto been derived from the products of distillation of wood; and it casts some light upon the cause or origin of natural gas.

STEAM TRAINS DRIVEN OFF BY TROLLEY IN OHIO.

The Cleveland, Akron and Columbus Railroad Company has taken off its road four passenger trains on account of the electric line competition between Cleveland and Akron.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

A DEMONSTRATION OF THE AIR-BRAKE IN BROOKLYN.

The gripman of Car No. 1 on the Montague Street line of the Brooklyn Heights Railroad Company had a chance to test the reliability of the air-brake recently placed on the car by the Standard Air-Brake Company of New York. The car was speeding along Montague Street at a rapid rate, when at Clinton Street, two intoxicated men attempted to cross the track. Seeing the car approaching they stopped to let it pass, but all of a sudden they made a dash and crossed directly in front of the car. The gripman realizing the danger, applied his brake and brought the car to a stop a few feet from the men, who not realizing the danger crossed safely.

ELECTROLYTIC REFINING AT ANACONDA.

THE Anaconda smelting plants have a combined capacity for producing 5,000 tons of pig copper per month. The electrolytic refinery is now producing 1,500 tons of refined copper per month. This plant is now being doubled, and early this year the output will be fully 3,000 tons of electrolytic copper per month at its own works.

APPARATUS WANTED AT LUDLOW, KY.

Mr. J. J. Weaver, civil engineer and superintendent, Ludlow, Ky., writes us: "I shall be in the market about March 1 for station apparatus and line material for a power house at Ludlow Lagoon. The apparatus will be for both light and power purposes."

BALL ENGINE PLANTS.

The power for the electric plant in the Young Women's Christian Association Building at Chicago, will be furnished by Ball engines built by the Ball Engine Co., Erie, Pa.

The Troy Iron & Steel Co., Troy, N. Y., are putting in a large electric plant of their own, consisting of three 115 H. P. Ball tandem compound engines direct connected to Westinghouse dynamos, and one 165 H. P. Ball tandem compound engine belted to Westinghouse dynamo.

ADVERTISERS' HINTS.

THE EMERSON ELECTRIC MFG. CO., of St. Louis, claim simplicity, efficiency and durability for their alternating current power motor. They also state that it will start with fifty per cent. overload.

THE ELECTRIC APPLIANCE CO. are prepared to make prompt shipments from their Chicago stock of celebrated "OK" weatherproof wire.

MORE THAN A THOUSAND MOTORS in use on the street railway systems of Brooklyn are insulated with "Micanite," of which the Mica Insulator Co. are the sole manufacturers.

THE STANDARD AIR BRAKE CO. wish it understood that they are not asleep, but that they are prepared to equip any car or electric locomotive in existence with the "Standard" air-brake; and, further, they say that anybody reading their new catalogue will have no doubt of it.

THE CALCULAGRAPH is now on exhibition at the bicycle show in Madison Square Garden, where all who are interested may examine this valuable instrument "for keeping tab."

SWITCHBOARDS in all sizes and for every style of plant are built and installed by the General Electric Co.

ONE HOUR TO CHICAGO would be the time required travelling with the velocity of a rifle bullet. The Metropolitan Telegraph Co. remind the public that with the "Long Distance" you can be there instantly.

THE CREFELD ELECTRICAL WORKS continue to make and sell every variety of insulated wires.

THE ELECTRICAL ENGINEER like wine improves with age, and on this principle alone, it being the oldest electrical journal on the continent, is the best. It has other claims, too.

CARBONS THAT WILL BURN, and purchasable at a moderate price, are advertised by F. S. De Ronde, the American agent for the famous "Ship" brand.

A. O. SCHOONMAKER, 158 William St., is now prepared to furnish mica discs and washers stamped out of India or amber mica. If you want anything in mica write him for information.

THE PENNSY LIKES IT.

The Pennsylvania railroad, encouraged by success in the east is planning to equip the Springfield, Ohio, branch of the road with electricity. Expert Crawford, of Altoona, Pa., has been instructed to report on the cost.

NEW ENGLAND NOTES.

THE CROSHAW COMPANY has been organized at Kittery, Me., for the purpose of manufacturing, doing business in and leasing electric lights and electric apparatus, with $100,000 capital stock, of which nothing is paid in.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have just completed for the town of Houlton, Me., a new iron bridge 300 ft. long and 18 ft. wide, with a sidewalk 5 ft. wide. The Bridge Company furnished the entire bridge, sub structure and super-structure complete.

THE HOME ELECTRIC HEATING COMPANY has been organized at Portland, Me., for the purpose of manufacturing and dealing in all electric processes for heating and cooking, with $500,000 capital stock, of which $30 is paid in. The officers are: President, S. W. Clifford, of Boston, Mass.; treasurer, T. H. Pearse, of Boston, Mass.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have just completed for the Ansonia Brass & Copper Co., of Ansonia, Conn., a new boiler house 65 ft. wide and 142 ft. long. The side walls are of brick and the roof is entirely of steel, covered with the Berlin Iron Bridge Company's patent anti-condensation corrugated steel.

NEW YORK NOTES.

MR. A. D. DORMAN, so well and so long known in connection with Brush interests, has joined the forces of the Adams-Bagnall Electric Co., of Cleveland, and will hereafter have charge of their New York office, which has been opened in Room 1302 Havemeyer Building.

UTICA, N. Y.—The Utica Electrical Manufacturing and Supply Company has elected the following directors: W. E. Lewis, W. H. Cloher, Jr., W. C. Ballda, M. J. Brayton, Utica, and Frank S. Ferris, Prospect. The officers are: President, W. E. Lewis; vice-president, W. H. Cloher, Jr.; secretary and treasurer, M. Jesse Brayton.

PHILADELPHIA NOTES.

NEW WILMINGTON, PA.—Col. W. A. Clark and Prof. W. J. Shields, of Pittsburgh, are about to begin the manufacture of storage batteries at this place, the battery being an invention of Prof. Shields.

WESTERN NOTES.

WARREN, O.—The Warren Electric and Specialty Company has elected T. H. Gillmer president, C. H. Angstadt vice-president, E. W. Gillmer secretary and treasurer.

DETROIT, MICH.—The Michigan Electric Co. has put up a huge sign for a local store, which includes 400 incandescent grouped in letters six feet long.

DETROIT, MICH.—The city council of Lowell, Mich., has employed Humphrey & Carr, engineers of this city, to proceed with the erection of an electric light plant within the next thirty days. The plant will be run by water power located eight miles from the city.

ST. LOUIS, MO.—A 1,500 K. W. generator in the Union Depot railway power house short circuited recently and the whole road was stalled for about 40 minutes. The armature is said to have presented the appearance of a huge fire wheel while it spun around.

THE ELECTRIC APPLIANCE COMPANY report that their sales of the Packard transformers exceed even their greatest expectations, and they claim that after handling the same for three years, they have yet to receive the first one to be returned, burned out by lightning. They also claim that they carry a complete line at Chicago, and can ship any orders *promptly* from stock.

THE EMERSON ELECTRIC MFG. CO. of St. Louis are agreeably surprised to find such a strong inquiry for their latest achievement in the alternating current motor line—their single-phase power motor. Although this article has been for sale less than thirty days, it bids fair to become one of their leading articles of manufacture within a few months. They are proving to be all that are claimed for them and the "guarantee" of the Emerson Co. is ample assurance of a high class machine.

Electric Lighting.

THE IDEAL ARTIFICIAL LIGHT.

BY

Elihu Thomson

READING over the article by Dr. W. H. Birchmore in The Electrical Engineer of Jan. 1, I note that the author has, in some of his work, simply formulated what has been the common experience, and what has been the growing experience of the past ten years or more, and, also, what has been known to every physicist, *i. e.*, that visibility depends upon the light which is being reflected having the same wave lengths as that which is used for illumination. Dr. Birchmore simply puts this matter on a scientific basis and emphasizes the conditions.

It has been commonly known that in a red light, containing low wave lengths, red colors are prominent while shades of blue become slatey and blackened, and tend to run into each other. With regard to the fact which he points out that the closing of the iris is due not simply to the rays proceeding from the object viewed but to the total rays which are transmitted whether they are used or not, I think it has been well known as a matter of common experience, though perhaps it has not been so definitely investigated as has been done by Dr. Birchmore. Every one knows that the presence of bright sunlight does not necessarily conduce to sharpness and clearness of vision, and that objects are even more readily distinguished in the shade, and this is more particularly the case when tints, or various depths of tints, are to be distinguished. Numerous instances of common experience might be mentioned in this connection illustrating these effects. The ordinary procedure of shading lamps which are to be used for reading, or shading the eyes when they are used in front of a light on a desk, are cases in point. It is true, also, that the color of the shade has an influence in making the light more pleasing or more effective for the purpose.

Along with other things Dr. Birchmore has pointed out, as a result of his observations, that violet light has vastly more power in its influence in closing the iris than has ordinary or yellow light. If these observations and the numerical relationship which he gives to the powers of these two lights in affecting the iris, are confirmed by further investigations, it will undoubtedly be of the greatest importance to make use of means for absorbing the higher rays of the spectrum or those which, without contributing much to actual illumination, still have the great power of affecting the iris which he mentions. If it be true, also, as I understand is claimed by Dr. Birchmore, that the incandescent light is rich in violet rays, or proportionately richer in violet rays than other forms of artificial illumination, then it would become a matter of great importance to apply the proper absorptive screens or media to get rid of such rays; and this conclusion would, of course, apply to every kind of light which might possess in too great a measure the power of closing the iris owing to the presence of the higher rays in undue proportion. I shall certainly look with interest to further developments in this particular portion of the field of research. It is difficult to see, however, why the incandescent lamp should have so large a proportion of the violet rays, as it is ordinarily run at a brilliancy which does not give even a true white light, but a light appearing yellow or orange as judged by ordinary unassisted vision.

I am glad to see that Dr. Birchmore endorses sunlight as the best illuminant. A believer in the doctrine of evolution must, of course, admit that the eyes of man have been developed more perfectly to use daylight than any other light. The old time ghastliness of arc lights seen at night, which ghastliness used to be talked about a great deal but which is seldom referred to now, I pointed out some years ago was due, in my opinion, to the accumulated experience of the race and the development thereof to expect that every light used at night should have a red or yellow tint. This education or inherited tendency has rapidly been evolved out of existence, and I may say that I regret even that the greenish ghastliness of the Welsbach burner does not seem to be one-tenth as offensive as it was on the first advent of the burner, which fact may, however, be due in a measure to a change in the composition of the network and not so much to education.

THE DETROIT MUNICIPAL PLANT FIGURES.

BY ALEXANDER DOW, ENGINEER PUBLIC LIGHTING COMMISSION.

THAT my "assumptions" as to municipal lighting costs should interest Mr. James I. Ayer, to the extent of calling from him a public criticism, indicates that further elucidation of these assumptions may interest the readers of The Electrical Engineer. Hence this communication.

Let me say first: I don't believe that municipal operation of street lighting is essentially superior to operation by a contractor either in cost or reliability; neither is it essentially inferior. Dynamos will run just as efficiently and reliably for a municipal corporation as for a lighting company, and men will work just as faithfully and just as hard for the one as for the other. If Mr. Ayer had built and operated his St. Louis street lighting plant for a municipality; if his control of operating force had been the same and the confidence given him by his employers the same, does he imagine that there would have been one iota of difference in the cost or certainty of operation because of the different ownership of the capital interested? Or does anyone who has met Mr. Ayer think he would have given less of his knowledge, or of his executive ability, to the service of the one employer than to that of the other?

To reduce the proposition to its simplest terms: Given the same management, the same results will follow no matter who furnishes the capital. Where municipalities have failed is just where private owners have failed,—either in lack of technical knowledge of the business or in lack of executive ability. And for each municipality which Mr. Ayer will name, that has been led into an unprofitable investment by the "ubiquitous politician" in conjunction with the iniquitous electrical salesman, I will show him (a) one company which has been put into the very same slough by the "leading local electrician" in combination with the salesman aforesaid; and (b) another company whose business has been spoiled not by the municipality under whose franchise it operates, but by

illegitimate private competition; which competition a municipality need never suffer from.

Next, I want to reiterate that Detroit was and is an exceptional case, both in the conditions of its local lighting companies and in its organization as a municipality. The circumstances which led to the establishment of a municipal plant here may never be duplicated in the experience of another city; and conditions equally favorable to non-political management exist in few cities of this size. Therefore municipal lighting should not be prescribed as a universal panacea because of its initial success in Detroit—not even because of its continuing success years hence. Every case must stand on its own conditions.

It is from knowledge of the local conditions that I venture on prophecy in answering Mr. Ayer's inquiry, "What is it reasonable to expect as an average cost for the next five years under municipal management?" I say that the average cost will be practically the same as it is this year. And I differ from Mr. Ayer as follows:

To begin: I renounce Whipple and all his works. So did every man now concerned in Detroit lighting, ever so many years ago.

Next: Detroit is not Chicago, neither like unto it; therefore reasoning by analogy is impossible. Chicago gets better service in its municipal lighting than it deserves, and it can get no better until it regenerates the very roots of its municipal system. I know also a little of that city, for I dwelt therein during certain recent years, and I want to say that no Moses ever sought to lead out of the wilderness a more perverse generation than that which has strayed behind Mr. Barrett. And I doubt whether Mr. Ayer, or my humble self, or any man who ever managed a lighting project, could have hustled or coaxed them further on the way than has their present leader. *I* would have quit trying long ago.

But while Chicago is discussed, let me ask, What is wrong with the municipal lighting of the South side parks and boulevards? That management is not hampered by politicians and political corporations, and the results are more than creditable; so that even Chicago shows in one spot the success of business management combined with municipal ownership.

Now to deny an implication. Mr. Dow does not now and never expects to assume that operating, maintenance, and interest for any period, either three months or longer, represent the total cost of municipal lighting or that the taxpayers of any city should be so instructed. He took particular pains to label plainly with name and date all the figures he ever gave out for publication, so that the newspaper man and also the wayfaring electric light man should read and not err; and should take those figures and add thereunto depreciation and taxes and insurance and water rent and (if so minded) the cost of buying Aldermen, and of standing off the opposition company; and play tag with the figures aforesaid to his heart's content. That's what figures are published for, anyway.

But Mr. Dow does assume, and sticks to it, that the "fixed policy" (in quotation marks) of keeping up every piece of apparatus to its original efficiency at the cost of operating account is the true way to work a "maintenance account"; and he further sticks to it that the expenses of this class charged to Detroit operating in the last three months are to all intents one-twentieth of the expenses so chargeable for the next five years. Furthermore that if the apparatus be kept up to its original efficiency, the cost of its operation cannot but continue the same.

Mr. Ayer is confounding the operating efficiency of apparatus with its value as a marketable asset. The two terms are originally related, but are not identical. And the first is immediately related to the "maintenance" account, while the second is related to "depreciation." Thus, if apparatus is maintained in such condition as to serve its original purpose with its original efficiency, the maintenance account is satisfied. But if the apparatus has to be so renewed or improved or added to, as to have an actual market value, in the current market, equal to its first cost; or if an account is opened to which is transferred year by year the difference between first cost and present market value, such expenditure or such account is "depreciation."

This last account is analagous to the putting up of margins in a stock deal. Of course, if a man owns the stock outright, and does not want to sell, the margins would only be on his own books and would be merely an interesting piece of mathematics until his heirs came to realize on the estate. A city corporation does not anticipate an administrator—its life is continuous—its franchise never expires.

Still the taxpayer should not (and does not, in Detroit) forget that he is liable to assessment for improvements or even for the making of repairs of the cumulative kind—on boilers for instance, on which the annual repairs are trifling for twenty years or so, after which a whole battery may have to be replaced or rebuilt because of the gradual reduction of the thickness of shells. The stockholder in a private company is liable to assessment in a precisely parallel way. Yet not one private company in a hundred thinks it necessary to put away in a strong box 5 per. cent. annually of the value of its boilers to provide for this twenty-years-distant occasion. This is what municipalities are asked to do, for the reason assigned that in contract lighting the contractor has to collect such a price as will ultimately cover the expense.

What I protest against is not the estimating of either a theoretical general depreciation factor, or of a charge to provide for keeping the plant "up to date"—a true "maintenance" charge is as already stated, a proper part of operating expense—but I want the depreciation cared for in the same way in the public case as in the private. To add 5 or 10 or 15 per cent. of the investment on to municipal annual costs is not the way to estimate a 5 or 10 or 15 per cent. depreciation. Because, in the municipal plan, the 5 per cent. stays in the hands of the taxpayers and is invested and re-invested and multiplied many times in the active business of each individual long before the twenty years expires. And because, conversely, the stockholders in the private company either re-invest their surplus over dividends (which is their depreciation fund) right in the company's business, or else divide it and use each man's share in his own affairs. The latter is the exact equivalent of the method in municipal lighting. The surplus need not be collected from the customers and divided among the stockholders because customers and stockholders are, man for man, and interest for interest, the same persons.

I have said that the taxpayers should not forget this feature of the business, and Detroit taxpayers do not forget it. There is little danger of their forgetting it so long as they have kind friends like Mr. Ayer and many others to remind them of it in the daily and weekly press. I do my share of reminding, when occasion offers, both in the press and out of it. They generally tell me (as one did to-day) that they prefer their depreciation fund left in their own business till the lighting plant needs it, rather than kept in a bank vault or in interest bearing securities, as is our city sinking fund; and much rather than in the coffers of some other fellow awaiting the time for the rehabilitation of the other fellow's electric lighting investment. The education in public lighting of Detroit taxpayers has been very thorough since those long departed days of Whipple.

Now as to the political "barnacles." I can tell the facts not only of three months but of thirty months' personal experience in hiring and discharging men for the engineering, construction, and operating divisions of the Detroit public lighting plant. The operating dates back over nine months—not three; the three months is the time since all contract lighting ceased. My experience is that "barnacles" do not apply any more, and have not for these two years. My early experience was that I got a few of them and summarily bounced them before they got their grip

made good. And the authorities approved of the bouncing. Also I find that non-political and strictly business commissions of management are an actual living reality of nearly three years in municipal lighting, and of a much longer time in other Detroit departments. Why should this not continue? A city gets just such government as it deserves; and so long as leading citizens—active men of business, of the best commercial standing—are willing to take control of city departments, so long will the city have as good management of its civic affairs as is given to the private affairs of its citizens.

There are others of Mr. Ayer's premises or implications that require a brief notice, in closing this communication. The statement that Detroit's operating cost, plus maintenance, interest, sinking fund to extinguish bonds, and a 5 per cent. theoretical depreciation is practically $100.00 per arc per annum, is substantially true. And it means that Detroit gets a 450-watt arc, keeps the plant in good running order, pays interest on bonds and creates a sinking fund to wipe out the bonds at maturity, and has another fund distributed among the taxpayers which will from time to time rejuvenate the plant, all for some $30.00 per annum less than it paid for a 360-watt arc "under competition between contractors." The demands which he says the plant "cannot meet" are the demands which under the contract system invariably swelled the annual lighting fund way above the contract by the promiscuous ordering of new lights to please "constituents." These demands could be met easily enough by a plant which has a duplicate boiler equipment and keeps a spare 350 horsepower engine and four dynamos turning over slowly during the early hours of the night to prevent (if possible) even one minute's extinction of street lights. It is not a case of "cannot meet" but *will not meet unless provided for by annual estimate.* And as to that contemplated expenditure of $150,000; when the estimates therefor shall have passed the Lighting Commission, the Common Council, and the Board of Estimates—the two latter being elective bodies—it may safely be believed that the authorized expenditures will not only be approved by the taxpayers, but will represent a profitable investment of public money.

DETROIT, MICH., Jan. 22, 1896.

AYLSWORTH'S NIOBIUM INCANDESCENT LAMP.

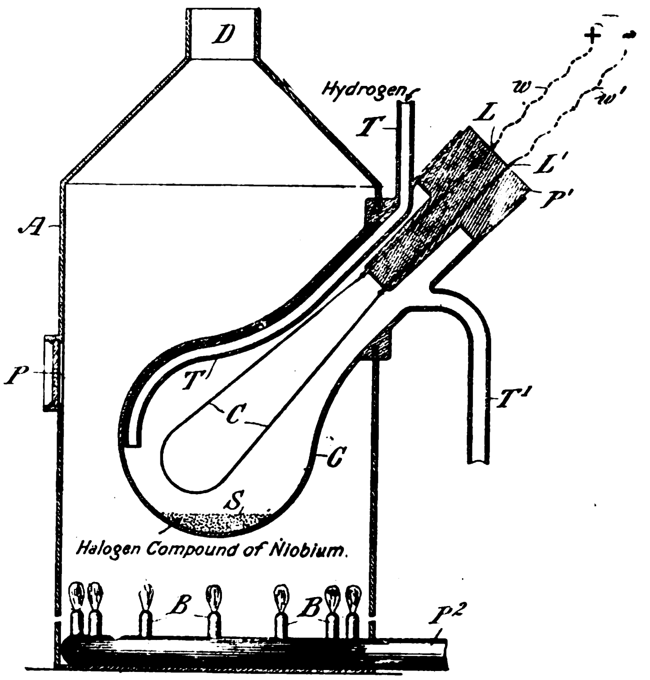
THOUGH carbon still maintains its hold as the material for incandescent electric conductors within lamps, nevertheless, attempts are still being made to substitute metallic filaments, of high melting points. The most recent work of this kind is that of Mr. J. W. Aylsworth, of Newark, N. J., who makes the incandescent conductor from such refractory metals as niobium, tantalum, molybdenum, titanium, zirconium, and other metals of the same group.

The method by which the filament is prepared consists in heating a base or support in the vapor of a volatile halogen compound of the element which it is desired to deposit, and simultaneously mix it with a reducing-gas, such as hydrogen.

In actual practice the process is carried out by means of the apparatus shown in the accompanying engraving. As will be seen it consists of a heating chamber A, provided with an outlet D for the products of combustion. The tube T admits the hydrogen gas under pressure and T′ conveys away the resultant gases or vapors.

Mr. Aylsworth takes an ore of the metal to be treated—such, for instance, as columbite, a well-known ore of niobium—and treats it by the well-known chemical process for separating the oxides of such metals and obtains in this manner niobium oxide. After the oxide is thus separated from its ore it is converted into a volatile halogen compound by the well-known application of mixing such oxides with charcoal and heating to a high degree of temperature in a current of dry halogen gas, such as chlorine or bromine. This halogen compound S is seen in position in the retaining-vessel G. The retaining vessel and its contents is then submitted to the heat of Bunsen burners and simultaneously a stream of a reducing-gas, as hydrogen, is passed through the chamber by way of the inlet and outlet tubes T and T′. A sufficient current of electricity is then passed through the conductors *w w* and the carbon or other base or support C to heat it to incandescence without rupture. There results from the union of the hydrogen gas and vapors arising from the halogen compound a deposit of the pure metal, as niobium, upon the filament base C. This process is continued until the deposit reaches the desired thickness.

Halogen compounds of any of the highly-refractory



AYLSWORTH'S METHOD OF PREPARING NIOBIUM LAMP FILAMENTS.

metals above referred to or any of the equivalent highly-refractory metals may be used in place of the halogen compound of niobium and the pure metals thereof deposited in the manner indicated. Mr. Aylsworth has succeeded in depositing in this manner tantalum, niobium, molybdenum, titanium, and zirconium, continuing the process in each instance until the carbon core or other conducting filament is surrounded by the metal.

A niobium lamp prepared in the manner described above has been run on test for some months past and shows very high efficiency and long life.

JAMESTOWN, DAK., ARTESIAN WELL LIGHTING.

A special dispatch from Jamestown, Dak., says: This city is struggling with the electric light problem and the proper degree of illumination of its streets. Pending the settlement all lights have been turned off. Up to January 1 the city paid $8 per month per light burning to midnight only. This rate is considered excessive. The city now has a fine supply of water from a 8½-inch artesian well, which is used for fire protection and also to furnish power to about twenty water motors in the city. Already the power of the well is taxed to the utmost and municipal electric street lighting is being considered in connection with the sinking of a proposed six-inch well. Such a well would furnish power to run an electric light plant, and the first cost of well and electric light plant would not be excessive.

CITY PLANTS NEVER DEPRECIATE.

The comptroller has purchased a draft for $1,900 and sent it to the Fort Wayne Electric Corporation in full payment for the new electric light machinery in the city station. By the way, the old dynamos are still in stock and can be purchased at a bargain. If anyone has a desire to invest, perhaps the caucus 18 can show them where there is a snap in the machinery.—*Bay City, Mich., Press.*

THE COST OF INCANDESCENT LIGHTING FROM CENTRAL STATIONS.

WE have received from Prof. W. D. Marks, president of the Edison Electric Light Co., of Philadelphia, a copy of a letter written in answer to an inquiry from Mr. Edison, as to the cost of incandescent lighting, which, in view of its practical importance, we print below in full:

Referring to your inquiry touching the cost of producing incandescent electric light from this station, assuming that you can furnish it with a 16 C. P. lamp, 20 to the H. P., it has had my consideration, and I beg leave to submit the following reply, which I trust will cover what you desire to know, taking particular cognizance of the commercial side of the problem.

The attempt to deduce the cost of producing incandescent light and power from the electric currents of small stations or isolated plants is apt to lead to error because many factors which do not appear in the smaller plants are of great importance in the large installations.

The cost of a large distributing system in the streets, if promptly and thoroughly repaired at all points where weakness develops, is no small item. The taxation of corporations in Pennsylvania is very onerous, which is also true in many other states. The clerical force required by a corporation for the proper transaction of its business and for the measurement of current and the writing of bills for same is large and costly.

The legal expenses and the losses of money from bills unpaid by unfortunate or dishonest consumers, mount up rapidly. Advertising, rents and soliciting agents all add to what may be called the contingent expenses, which cannot be predetermined.

Finally, after a station has been in operation for about three years, the constant renewals and repairs to steam machinery and electrical apparatus form a considerable item of cost, which cannot be avoided, since the machinery must always be ready for immediate and perfect operation. It is only by constant and thorough renewal of every part of the machinery showing weakness that a station can deliver an *unfailing and regular light*, without which dissatisfaction arises and failure is certain to follow.

Taking the case of this station from July 1, 1894, to July 1, 1895:

The average number of lamps connected is...	89,359
The total number of 16 C. P. lamp hours sold is..................................	62,702,714
Gross income from light and power, one year	$411,315.80
Income per lamp attached..................	$4.60
Income per lamp hour ($\frac{447}{1000}$ Amp. hour) sold.	$\frac{656}{1000}$ ct.

The expenses of producing light may be divided, approximately at least, into two classes: 1. Fixed charges, amounting to an annual charge on each lamp. 2. Proportional charges, varying with the amount of current produced. Neither one of these classes can be accurately separated from the other.

It may, however, be assumed that when a station has about 100,000 lights attached, that up to 150,000 lights, the following accounts will not be much increased, if at all:—Salaries, Rent, Insurance, Taxes and Royalty, Interest, Discount and Exchange, Office Expenses, Workshop Supplies and Expenses, General Expenses, Dynamo Room Pay Roll and Repairs, Engine Room Pay Roll and Repairs, House Wiring Inspection, Meter Expenses, Repairs to Electrical Apparatus, and Street Repairs and Maintenance.

The following expenses increase with the current sold by the station: Oil, Waste and Packing, Lamp Renewals and Coal. (In coal is included all its labor, handling and firing it and repairs to boilers, as well as to removal of ashes.)

The aggregate of the Fixed Charges is......	$132,677.99
An average cost per lamp attached of......	$1.46 per year
The aggregate of the proportional charge is..	$88,132.78
An average cost per lamp hour sold........	$\frac{1405}{10000}$ ct.
Average burning of lamp per year..........	701.7 hours.
Average cost of lamp per year, proportional charge..................................	98.6 cents.

Thus on one year's business,

Income from each lamp per yer..........		$4.60
Fixed charge on each lamp per year......	$1.48	
Proportional charge on each lamp per year,	.99	2.47
Profit on each lamp per year............		$2.13

Or, reducing to Lamp Hour standard,

Income from each lamp per hour.......		.656 ct.
Fixed charge on each lamp per hour....	.21 ct.	
Proportional charge on each lamp per hour..................................	.14	.350
Profit on each lamp per hour...........		.306 ct.

This analysis of the actual expenses of one year's run with 89,359 lamps enables us to look into the proper method of increasing the profits of this station.

If we increase the number of lamps attached without increasing the number of lamp hours averaged by each lamp, the profit arises from a diminution of the fixed charges per lamp. Thus assuming 120,000 lamps attached, the result is as follows:—

Yearly income from each lamp............		$4.60
Fixed charge each lamp....................	$1.11	
Proportional charge each lamp............	.99	2.10
Profit..................................		2.50
Total profit, 120,000 lamps................		$300,000

This is the limit of profit of station, machinery and conductors, as at present installed, provided the average hours of burning are not increased.

We have, however, room for machinery for 150,000 lights attached.

Estimated value of machinery for 30,000 lights attached..............................	$125,000.00
Additional street conductors................	125,000.00
	$250,000.00

The average hours of burning per day of lamps, from which we have deduced the cost per lamp hour, is nearly 2 per day.

An investigation of the possible profit arising from increased hours of burning will show the advantage to be reached by long hours.

FOR 120,000 LAMPS ATTACHED.

Hours use.		Income per year.	Cost per year.	Profit per lamp per yr	Total annual profit.
Per day.	Per year.				
2	730	$4.79	$2.16	$2.63	$315,600
4	1460	9.58	3.16	6.42	770,400
6	2190	14.37	4.18	10.19	1,222,800
8	2920	19.15	5.21	13.94	1,672,800
10	3650	23.94	6.23	17.71	2,125,200
12	4380	28.72	7.26	21.46	2,575,200
24	8760	57.46	13.41	44.05	5,286,000

The large results from long hours of use point to great concessions which can be made for long hours of motive power work.

The present investment of $2,000,000 should not, for obvious reasons to all business men, declare a dividend greater than 10 per cent., or earn a profit greater than 15 per cent.

This makes, with $2,000,000 investment and 120,000 lights attached, $300,000 per annum.

Our present minimum rate yields per year.........	$3.18
Cost per year..	2.10
Profit..	$1.08

A yearly profit of $128,600.00.

Long hours of use of current point to large concessions in the way of discounts, which will enable the cheaper use of power and light.

FOR 120,000 LAMPS ATTACHED, $300,000 ANNUAL PROFIT.

Hours use.	Annual profit at present rate.	Discount to reduce profit to $300,000.
2	$315,600	None.
4	770,400	60%
6	1,222,800	75%
8	1,672,800	82%
10	2,125,200	85%
12	2,575,200	88%
24	5,286,000	94%

As the machinery of this station is estimated to carry one-half the lamps attached, 24 hours with 120,000 lights is impossible. Likewise an average of 4 hours for the whole number of lights practically means 8 hours for one-half that number, and therefore the discounts should be one-half that shown in above tabulation.

Therefore, in making contracts for long hours of use of motive power or light, the discounts should be as follows:

YEAR OF 365 DAYS.	DISCOUNTS.		NET PRICES.	
	Per lamp per day.	Per H. P. per day.	Per lamp hour.	Per H. P. hour.
Minimum Charge.......	1 cent.	10 cents.		
2 hours..................	None.	For 2 H. P. & over, none.	¾ cent.	7½ cents.
4 "	30 per cent	30 per cent.	.525 "	5¼ "
6 "	37½ "	37½ "	.469 "	4.69 "
8 "	41 "	41 "	.443 "	4.425 "

The foregoing has been upon the assumption of a 50-watt, 16 C. P. lamp, and points out very clearly the existing costs, their nature, and under what conditions it is possible to reduce the cost per lamp hour by suitable discounts, without loss to the station or company.

Taking up your suggestion of 20 lamps to the H. P., equivalent to 37½ watts per lamp; this station, which can carry 150,000 lamps of the present economy of 50 watts, should be able to carry 200,000 lamps of 37½ watts and 16 C. P.

The aggregate of the fixed charges for one year on this station is $132,677.99, which would give an annual charge on each attached lamp of 66 cents.

The average cost of the proportional charge, due to coal, oil, waste and lamp renewals, should be ¾ of .1405 cent, or .1053 cent per lamp hour sold, assuming these lamps to have the same life.

Thus on one year's business the fixed charge on one lamp attached would be 66 cents; and assuming that each lamp burnt 701.7 hours, the total proportional charge is .1053 × 701.7 or 74 cents, which, added to 66 cents, already charged, would make $1.40 cost per annum, without any increase of the investment beyond $2,250,000, shown above. Assuming the profit required on $2,250,000 to be 15 per cent., we would have as the profit required of the station, $337,500.

The cost of running 200,000 lamps would be $1.40 × 200,000 or $280,000. Adding this to the profit required, we have $617,500 as what should be produced as a gross income from 200,000 lamps, or requiring $3.08 gross income from each lamp.

Assuming that these lamps burn (as learned from experience) 701.7 hours each year, the charge per lamp hour would have to be about .43 cent, equivalent to a gas charge of 86 cents per thousand cubic feet, to produce 15 per cent. profit on the invested capital, $2,250,000.

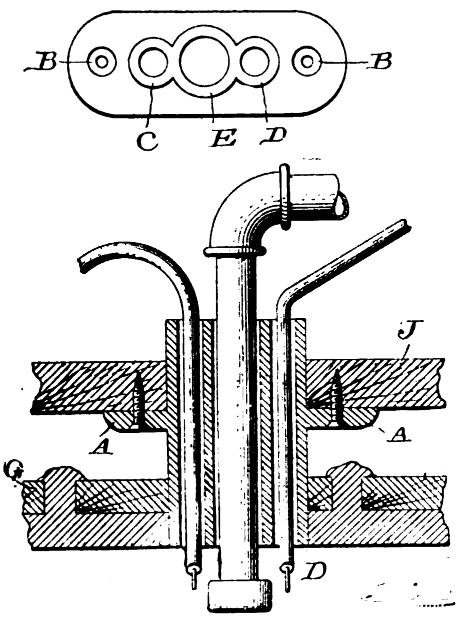
This, I believe, answers the questions which you have asked, assuming that lamps at 20 to the H. P. are burned the number of hours found as an average at this station.

The matter of discounts from long hours of burning will require similar treatment to the case I have already stated for lower economy lamps.

THE CASE OUTLET INSULATOR.

THERE is yet much room for improvement in house wiring appliances, and a step in the right direction has been made by Chas. F. Case of Akron, O., by the invention of an outlet insulator designed to protect wires at outlets, a matter that has perhaps caused as much trouble between wiremen and inspectors as anything else.

As will be seen from the illustrations it provides for bringing



FIGS. 1 AND 3.—THE CASE OUTLET INSULATOR.

the wires through porcelain tubing and keeping them rigidly the proper distance apart, the whole being made in one piece. In Fig. 1 and 2, C D are the tubes, A the plate connecting them together; B B the screw holes by which they are fastened to the lath or ceiling; and E a centre hole between the tubes allowing it to be put on over a gas pipe.

While the device is useful in keeping wires away from the gas pipe it is especially useful in keeping wires the proper distance apart and holding tubes in place where there is no gas pipe, in which case the plate *b* rests on top of the lath.

UTILIZING THE SCORCHER.

Various devices have been invented for enabling the cyclist to train or take his exercise indoors during bad weather. It has occurred to a French electrician that he might at the same time be doing some useful work. Accordingly, an apparatus is described in *L'Etincelle Electrique* by which the driving wheel of a safety bicycle of the usual type is raised from the floor and by means of a strap and speed gearing drives a small dynamo which is used to charge accumulators. The arrangement is designed to give a current of seven amperes at 20 volts.

DENVER, COL.—The Mountain Electric Co. has received a contract for lighting the capitol with two Western Electric direct-connected multipolars and Armington & Sims engines, to carry 2,000 lights.

LINCOLN, ILL.—The contract for constructing Lincoln's new electric light plant has been awarded to E. B. Herman & Co. The new concern will have one thousand incandescent lamps and the contract is to be completed in sixty days. The contract price is $2,200.

KEARNEY, NEB.—At the last meeting of the directors of the Kearney Canal and Water Supply Company and the Kearney Electric Company, Frederick K. Walbridge, of Brooklyn, N. Y., was elected president, in place of George W. Frank, Sr. Mr. Walbridge puts $50,000 into the business of the two companies, and promises that it will all be used for the enlargement and improvement of the business. Work will commence as soon as possible in the spring and be pushed forward as rapidly as consistent with good work.

NEWS AND NOTES.

THE UTILIZATION OF ACCUMULATORS AS RESISTANCES.

M. NODON directs attention to the advantages of using accumulators as a substitute for resistances in electric installations, in an article in the *Revue Internationale de L'Electricité*. It goes without saying that a considerable amount of energy is absorbed in resistance coils, which is irrecoverably wasted in heating the surrounding air. If a battery of accumulators is substituted for such a dead resistance, the electrical energy, instead of being lost, is in great part stored up in a form which may be afterwards utilized when required. M. Nodon quotes an example of an installation in which this principle was taken advantage of. A Gramme dynamo driven by a 2-horse petroleum engine gave a current of 30 amperes at 75 volts. This dynamo was coupled to four differential arc lamps arranged in parallel, and each taking a current of 8 amperes. Each of these lamps was fitted with a German silver resistance to reduce the voltage of the machine to the required amount. At one lamp the resistance was replaced by a battery of 10 Faure accumulators which were charged during the working of the lamp with a current of 8 amperes. The lamp with the battery was observed to work much steadier than those with the wire resistances, and sufficient energy was stored in the accumulators to light five 10-candle lamps during the whole night. With alternating currents it is proposed to use a rotary transformer to charge the battery. M. Nodon ends, however, by confessing that the use of accumulators as resistances is not likely to become general till their first cost and cost of maintenance has been considerably reduced, and expresses a fervent wish that this may soon take place, in order that their great advantages when used in this way may be realized.—*Lond. Elec. Rev.*

THUNDERSTORMS.

M. Albert Nodon has communicated to *L'Electricien* the results of certain researches made in connection with the department of physics at the Sorbonne. A Mascart electrometer was connected by a thin insulated copper wire to insulated metallic discs placed at some distance from each other in the open air, and it was found that the maximum potential obtained was the same during any one storm, and was independent of the distance of the disc from the spot where the lightning discharge took place. It is concluded from this that a thundercloud acts as an efficiently good conductor to be considered as presenting an equipotential surface, and that the electrical equilibrium, so far as the cloud is concerned, is rapidly re-established after each flash of lightning. It was possible to tell when a flash was about to occur by noting the rate at which the electrometer readings progressed towards the maximum.

CONTINUE TO DO GOOD.

I am glad to have an opportunity to speak my praise of the article on Edison station methods in your issue Jan. 8th. Trust you will continue on in such journalism.

W. E. HARRINGTON.

PHILA., Jan. 24, 1896.

Power Transmission.

THE SCHOENENWERD, SWITZERLAND, 3-PHASE INSTALLATION.

THE boot and shoe factories of Messrs. Bally & Sons, situated in the vicinity of Aarau, are among the largest in the world, the daily output of 6,000 pairs of shoes and boots, of all conceivable kinds and sizes, being exceeded only by a factory in the United States. The principal of the three factories, employing 4,000 hands, is situated at Schoenenwerd, near Aarau, on the

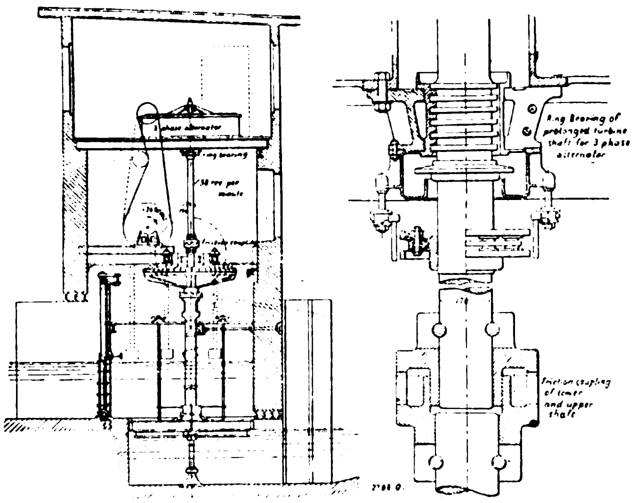


FIG. 1 AND 2.

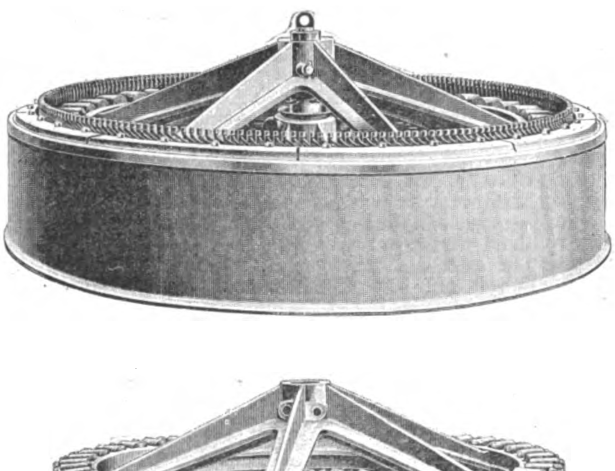
River Aare, on the Zurich, Berne and Geneva trunk railway. This factory was until recently equipped with a Jonval low pressure turbine driving continuous current dynamos which furnished current for lighting and for one 24 H. P. motor and two 10 H. P. motors in a branch factory one half mile away on the other side of the Aare, while during spare hours, it charged a battery of accumulators for lighting dwelling houses near the factory.

For the better utilization of the power a 3 phase distribution was resolved upon with a 100 H. P. 3-phase generator, mounted direct on a prolongation of the turbine shaft and the new dynamo shaft is shown in the illustrations, Figs. 1 and 2. The

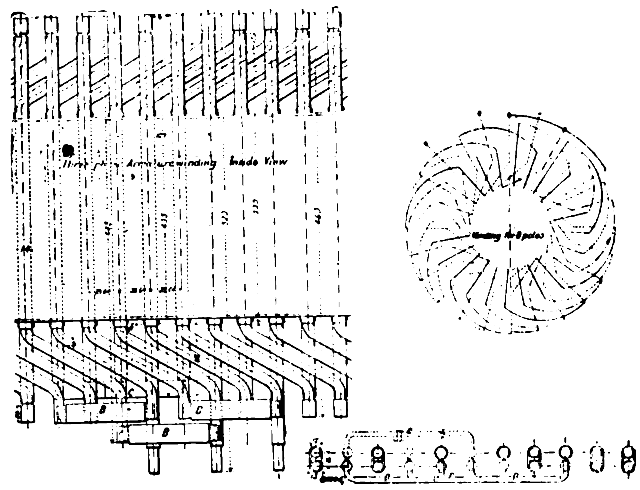


FIGS. 3 AND 4.—BROWN THREE-PHASE ALTERNATOR.

turbine wheel is 3.6 metres (12 ft.), the upper shaft 17 centimetres (6.7 in.) in diameter. The weight of the dynamo of 8 tons on the shaft is not counterpoised, but is supported on ring bearings, as shown in the engraving. There are six rings running in a gun-metal bearing, and below the bearing there is a broad chamfered collar to catch the oil that runs through and direct it into a catch-dish. The old lower shaft of the bevel wheel is connected with the upper shaft by friction coupling (Fig. 2).

Three-Phase Installation (Figs. 3, 4, 5, 6 and 7).—This was carried out by Messrs. Brown, Boveri & Co., and had to be adapted to more or less peculiar and complex conditions, viz.: in order to save space, and, moreover, loss by gearing, the alternator had to be mounted on the turbine shaft, making only 80 revolutions per minute, involving very low periodicity; and in order to be available not only for power, but to a small extent also for lighting without transformers, it had to be designed for low voltage. The machine consists of a circular gun-metal frame carrying the stationary armature, and of an inside six-armed spider flywheel carrying the rotary magnetic field, the latter being 2.7 metres (8.9 ft.), the former 3.15 metres (10.4 ft.) in diameter. The magnetic field is shown in a separate illustration, Fig. 4, and is composed of no less than 80 rectangular poles cast with the rim of the spider wheel. Forty of these pole-pieces are naked, while the 40 intermediate ones carry insulated wire coils wound on paper frames which fit the pole-pieces. To prevent the wire coils from moving or becoming loose, there is fitted and screwed to every adjoining naked pole-piece a rectangular brass guard frame or shoe whose wings extend to the edges of the two adjoining pole shoes, and press against the wire coils, thus holding them securely in position. The armature coil, clamped between the inner rings of the frame, consists of insulated laminæ of sheet iron with a double row of circular equidistant holes near the periphery, into which are inserted insulated copper bars in two rows of 240 bars each.

The upper and lower ends of every pair of front and back bars are respectively soldered together, the back bar having its upper portion bent in one direction, while the front bar has its lower portion bent in the opposite direction, as shown in the diagrams, Figs. 5 and 6. The arrangement thus constitutes a drum rather than a star winding, and is also shown, for eight poles, in diagram



FIGS. 5, 6 AND 7.

Fig. 7. At 80 revolutions per minute, or 0.5 revolution per second corresponding to $0.5 \times \frac{80}{2} = 20$ cycles per second, the output of the machine at 178 volts is 250 amperes multiplied by 1.73 for three phase, or 74 kilowatts or 100 horse-power. The exciting current is derived from a 40 horse-power direct-current bi-pole dynamo, already mentioned, which makes 670 revolutions, and is driven by bevel gearing from the same turbine as the generating alternator. The excitation is 17 amperes at 200 volts, equal to 3.4 kilowatts, or 5 per cent. of the effective output of the alternator. The total weight of the machine is 8 tons, equal to 121 kilogrammes or 266 lbs. per kilowatt of effective output. The loss due to armature reaction is 3.85 per cent., and the efficiency, including excitation and all frictional losses, is $\frac{90}{100} = 90$ per cent., under all conditions of working.

Motors.—The three-phase generator drives in different parts of the factory ten three-phase motors, each making 600 revolutions per minute, there being eight motors of 10 horse-power, one of 5 horse-power, and one of 1 horse-power, total 86 horse-power. They run absolutely noiselessly, and easily give 50 per cent. above their normal power. One of the 10 horse-power motors drives by belt the fan of the hot-air heating apparatus, which can also be coupled to a small 10 horse-power impulse turbine working under a pressure of 75 metres (246 ft.). On one occasion the belt was taken off the motor pulley and put on that of the turbine and then back again in the writer's presence; the motor on being switched on again, attained its full speed in a little over a second. For some of the operations which require motors with very low voltage, transformers are used which convert the 178 down to 10, volts.

We are indebted to London *Engineering* for the above details.

ELECTRIC ELEVATORS, WITH DETAILED DESCRIPTION OF SPECIAL TYPES.[1]

BY FRANK J. SPRAGUE.

THERE has been so much written on the subject of electric elevators which is pertinent to the subject, that in presenting this paper I shall make free compilation from others, and, supplementing these extracts with some new matter, I shall by lantern views illustrate some details of the more recent machines, their methods of manufacture, and some steps in their development. The time has passed when any one can doubt that one of the most important applications of the electric transmission of power, and one in the number and variety of its applications already rivaling the electric railway work which has made such marvelous strides in the past eight years, is that of the operation of all classes of hoisting machinery. Some idea of the extent of the present elevator business may be gathered from the fact that in New York City alone there are not less than 5,000 elevators of various kinds, more, in fact, than there are street cars, and more people are carried vertically than there are horizontally.

Ignoring for the moment the specific methods of application, and discounting the difficulties naturally met in developing machines to do the duty required in modern office work, not alone the technical difficulties, but those commercial ones naturally met when a new company enters the lists with untried machines against the entrenched forces of existing industries, there was still much of encouragement to be derived from a backward glance at the industrial changes wrought in the last few years, and to all objections raised there came the natural queries: Is the elevator field, great as it already is, limited to the possible application of a water or steam motor? Is there no wider, no more universal application of power for this class of service than has hitherto been presented? Is the hydraulic elevator the one bulwark to stand up against the assaults of the electric giant? Does it present such fixity of design, unity of purpose, refinement of processes, economy of operation and freedom from accidents as to preclude improvement if using some other power?

Let us look at the record in other fields and ask: Why has the trolley system, born only eight years ago, driven the horse from the street? It involves great initial expense, the conversion, distribution and reconversion of energy. It faced all the powers of conservatism, ridicule and fear. It had to combat the allied forces of the Bell telephone interests tested by court action in over twenty States. It had the opposition of the strongest municipal and corporate influences. Every detail of the system had to be created, and yet it stands to-day unrivaled in its industrial progress.

Why is the same trolley system driving the cable to the wall, and why has its adoption marked the abandonment of a plant costing not less than $3,000,000, in the city of Philadelphia? Are there many more examples of the direct applications of force than the cable system, many closer connections between a great engine built for the highest economy and that which it moves?

Why is the steam locomotive giving way to the electric motor on suburban service? Is there any more direct example of the application of steam than is presented by a locomotive, the power of whose cylinders is transmitted directly to the drawbar through the intermediary only of a crank?

Why does the best shop practice dictate the abandonment of the slow speed highly economical Corliss engine and the direct application of power by belts and shafting, and adopt the high speed engine and direct-connected dynamo at a central station, with the conversion, distribution and reconversion of energy by a dozen different motors at a greatly increased initial expense? Is it for any other reason than convenience, reliability and economy of operation?

Why has every overhead crane builder in the United States within the past four years absolutely abandoned wire rope, square shaft and hydraulic transmission for the three-motor transmission which I advocated only nine years ago? It is because it is simpler, because it will cost less, or because it is more economical, more flexible, and because it answers the purposes better than the other and more direct systems. Why have the great central stations of the country adopted electricity for the transmission of power to the hundreds of industries within the radius of their supply, and into what form of energy is the power of Niagara being converted? In short, why is the transmission of power in almost every case where flexibility, convenience, economy, efficiency and reliability are required depending upon the electric method, not only in new work, but oftentimes to the replacing of older plants?

The elevator field, indeed, is a large one, and if the system is electric, then, considered from a commercial standpoint, there appear the following possible classes of work: 1st. High speed passenger service where no hydraulic plant is possible because of limited space. 2nd. High speed passenger service in competition with hydraulic plants, the electric plant doing equal duty, costing less, occupying less space than the hydraulic, and costing much less to operate. 3rd. Substitution of new high-speed electric service in place of old steam and slow hydraulic services in buildings where the limited space and interference with operations will not permit consideration of a new hydraulic plant. 4th. Passenger elevator service in buildings where the loads are comparatively light. 5th. Passenger service in private houses where safety, simplicity and noiselessness are essential. 6th. Freight and special classes of work. For convenience we may classify elevator work as "first-class, that requiring speeds from 300 feet to 600 feet a minute," including the first three duties above mentioned, and as "second class, those requiring speeds of from 50 feet to 250 feet a minute," which include the remainder.

In general, there has been required and developed two kinds of machines to perform these services. The first is the outcome of the increased height of buildings and the demand for high speed and smooth motion, largely regardless of cost of apparatus, space occupied, or cost of operation. The hydraulic elevator was the result of this demand, and was the only one that up to a year or so ago was accepted for this service.

It was to meet this demand—by creating an electric elevator which would do the work equally well, if not better, than the hydraulic—that the elevator to be more specifically described, was developed under some unexpected difficulties.

Of course, such a machine must have the speed and capacity of the hydraulic elevator. It must be absolutely safe. It should have advantages in the matter of space, and must be more economical to operate.

The second class of elevator work, that which requires lower speeds, is applied to small apartment houses and other buildings where lighter elevator duty is required. This, for a long time, has been fairly supplied by worm gear elevators, and the replacing of the steam engine by an electric motor has enormously broadened the field for this class of machine. These two machines, however, are not equivalents. They present two distinct kinds of rope movement, two absolutely different methods of control, and two varieties of safeties.

Just here I will briefly outline some of these differences, for they constitute in my mind vital essentials, and are absolutely determinate in their limitations. The rope movement on the hydraulic is provided by an expanding set of sheaves on which all the ropes are maintained in fixed planes. Four to six ropes can be used on the machine, and six to eight on the car. The sets of rope can be equalized at the machine, and they have a fixed lead in the hoistway. The machines can be double and treble decked, and they have absolute limits of mechanical travel. All of these features are of the greatest importance when dealing with high lifts, large powers and fast travel.

The drum machine, while having a distinct field of its own, and a most useful one, has not a single one of the characteristics mentioned. It cannot well use over two ropes on the drum, and they cannot be equalized at the machine. The lead is a shifting one, and on long lifts this may be as much as from four to five feet. These particular objections have been met in a type of machine which may be called a cable drum machine, where the drive is by friction of the rope in the sheave grooves, but in both these machines, the plain drum and the cable drum, there is the very grave objection that there are no fixed limits of mechanical travel which are independent of the armature movement, and on fast speeds particularly, this is absolutely essential.

In the drum machines the driving power is applied through one or more worm gears. In my own practice on light service, such as house automatic machines, and a low class of freight work, I use a single gear with double ball thrust bearings, and on heavier work, a right and left handed gear generally cut on the Hindley form, to give the fullest amount of gear surface, and with the shafts connected by independent machine-cut spur gearing, which allows the worm gears to be free from each other.

There is another distinction—that of control. The hydraulic machine is necessarily a gravity machine, using power only in hoisting, its speed on the down side being controlled by the rate of water exit. The machine is, of course, under counter-weighted. In the drum machine, when there is any attempt at economy, over counter-weighting is generally used, part from the car and part from the back of the drum, the over counter-weighting being approximately equal to the average load.

With these two types of apparatus as precedents, the problem was:

How far can electricity be applied? What are the limitations of control? What the conditions of installation and operation, and to what extent could one type be eliminated? And the answer is: Both types must be used, but for distinct classes of service.

Taking the drum type and considering electrical control on a machine over-balanced for average service, the load up or down is sometimes with and sometimes against the machine. To control such a machine directly from a supply circuit (and I cannot seriously consider any other, no matter how ingenious or refined, as meeting general conditions), there is one method only, and that is the use of a rheostat in starting, and the inverse variation of the strength of the shunt field for about a two to one variation in speed. A cumulative series coil is only permissible in starting if variations of speeds are controllable, and in any event these variations are limited. Such a machine is, however, the best for second-class service.

1. Read before the American Institute of Electrical Engineers, Jan. 22, 1896.

Every one is familiar, of course, with the conditions of ordinary freight work. I might, however, here point out an important branch of this industry, and one which is destined for every wide application, and that is, automatic house service, the machine to be controlled without an operator, and so installed as to be as safe as a stairway.

Briefly, such a machine, on my system of working, is equipped with an interlocking switch device on the machine, having a coordinating movement with it, and with the controlling circuit in series with a number of door switches automatically opened or closed with the doors. The doors themselves are fitted with mechanical locks, allowing a car to be opened only during a range of movement from 6" above to 6" below. At each floor is a single controlling button. If the machine is at rest, the pressing of a button calls the car, wherever it may be, to the particular floor at which it is wanted, where it automatically stops. When the door is open it cannot be started, and when running, no one else can call it from the floor for which it is destined. The machine also has an additional control in the car, and the safeguards attending its operation are such as to make it safe for servant, nurse, child or invalid.

The development of the multiple screw elevator was undertaken for the express purpose of supplanting in a large way the former standard for high duty office service, and although not by any means an easy problem, either electrically or mechanically, a knowledge of what the hydraulic elevator is, and the variation of the types existing, gave adequate reasons for its attempt.

Let us consider for a moment a hydraulic system, and institute a few comparisons. It consists primarily of a steam cylinder, or a multiplicity of steam cylinders, working ordinarily under poor conditions of steam economy, that is, with a fixed cut-out in the high pressure cylinder of a compound pump or no cut-off in any cylinder of a simple pump. This element corresponds to the cylinders of a steam engine in the electric system, which use steam expansively with a cut-off varying according to the load, and under pressure conditions which are somewhat better than exist in a pump. It is to duplicate the results of this system of variable cut-offs and steam expansion, that the energies of the various pump builders have been more or less ineffectually bent for a great many years in plain acknowledgement of that defect in their simple and duplex pumps, the latter of which is common to almost every hydraulic plant of any size in the United States. It is true that a so-called "high duty" pump with equalizing piston is used on some of the larger elevator plants, but its use has not proven by any means entirely successful, because of the spasmodic nature of the service. Among the high duty pumps, the flywheel type, such as is used on large water pumping stations has been attempted, but rarely, I may fairly say, with success. The next element is the water cylinder, which corresponds to the dynamo in the electric system, and on account of the high friction due to the packing, the efficiency of a water cylinder with its valves is not ordinarily equal to that of a dynamo, which with a motor stands to-day the typical example of an efficient energy converter.

The next element is the piping and the tanks, compression or roof, and perhaps an accumulator, into or through which the water is pumped for delivery to the controlling valves of the elevator, and that which corresponds to this in the electric system is its simple wiring, and if a storage battery is used, then this last in conjunction with it.

Any competent engineer knows that, measured by standard practice, a given number of pounds of energy can be delivered to the controlling apparatus of an electric elevator for less pounds of steam, that is, water evaporated, through the medium of no less than fifty combinations of engines and dynamos, than can be delivered to the valves of any hydraulic cylinder through the standard pumps permissible in average elevator service. To be specific, the average water evaporation on a compound duplex pump, which is almost universally used, will in practice, be not less than about 60 to 70 pounds per horse-power of water energy delivered to the controlling valves, whereas the electric combination will easily give the same for less than 40 pounds. There are exceptional conditions in which a higher economy can be gotten in a hydraulic system, but they are few and are not typical, and under equal conditions the steam consumption in an electric system can be cut in two.

But this is not all. The fact is persistently ignored, although the attempt is made to offset it by recent experiments with a differential piston, that a standard hydraulic elevator uses the same amount of water under the same pressure for every foot of travel of a car, which volume of water and pressure are determined by the maximum load which has to be carried, although the average load on the ropes, including the excess of car over counterweight, is not over one-third of the maximum. On the other hand, the electric elevator uses, and must use, under normal conditions, current directly proportional to the work, modified in a small degree by starting and slow running. In short, over and above the friction load of the generating system, the steam consumption in the engines and the generation of electricity in the dynamo vary with the demand of the elevator machines. It is a system which is of necessity automatic.

On the other hand, the hydraulic system is one of the most flagrant violators of the relation which should exist between demand and supply. It is a system of transmission by water, having at one end a generating plant doing full duty for every foot of travel of its piston, with a variable duty on an elevator car at the other end, and an intermediate straight line water engine with its pipes and tanks taking care of that variable duty and using the balance of its energy in heating the water which passes through its valves.

Lack of economy, however, is not the only objection to the hydraulic system when looked at from the architect's or builder's standpoint. Until recent developments, these have always been strictly handicapped, not so much perhaps in the matter of cost, but in the internal arrangements of the building as well as in the lay-out of the basement, neither of which could be finally and satisfactorily, if even then, determined, until the particular type of machine had been accepted by the owner, and the contract finally made for it.

Nor has there been either singleness of design or unity of plan of operation. Each maker has had his own form of construction, his special method of control. Every building has brought up a problem more or less new, or at least conditions which had to be seriously considered in determining the elevator service. Horizontal and vertical machines, in basement or shaft; high or low multiplications; long and short, single and jointed cylinders; big and little diameters; large and small sheaves; free and suspended counter-weights; pulling and pushing machines; direct and differential pistons; roof tanks, stand pipes, accumulators and compression tanks; high and low pressures; hand rope, wheel or pilot-valve control; simple or compound pumps—all have made a nightmare of complications, giving more initial and continuing source of complaint and dispute than all the other engineering problems in a building.

So what more natural than that they should turn to electricity for emancipation? And this tendency is augmented by other reasons.

Leaving out central station supply, always, when properly equipped, to be preferred when the electric service is of a spasmodic or limited character, and considering for the present those large plants which characterize the modern office or hotel building and in a way rival central stations, every engineer knows that the fewer the number of well-proportioned units, the more alike they are, the freer the interchangeability between themselves, and the extent to which any one unit can be utilized, the better the system for power generation and conversion, no matter what its character.

The best modern practice makes a three-unit direct-connected engine and dynamo plant the best for lighting a building. There is an empirical relation existing between the number of lights required in a building as ordinarily designed, and the elevator service. When, in addition to the lighting service, such a building adopts electric elevators, it is not now necessary that it shall add an independent generating plant.

All that is required is that the three units should be somewhat increased in size and, perhaps, one of them preferably divided, the mains all taken to a common switchboard with two-way switches, and every engine and dynamo thus made interchangeable on either the lighting or elevator circuits, and at times both, especially if using a slow acting corrective converter, some of each can be run from the same engine and dynamo. So, instead of five or six units, some water and some electric, the entire generating plant is reduced to a single system consisting of three units of one size, or two of that size and two of a half size, which can be run interchangeably, and one of which is almost always in reserve.

Just here it is well to consider the probable application of the storage battery which, if built with plenty of lead, with large surfaces and for heavy momentary discharges rather than for long time steady discharges, will prove a most important adjunct to elevator service, which, like railway work, is spasmodic in character.

A modern office electric elevator on actual average service requires an expenditure of about one kilowatt hour per car mile of travel for every eight or ten feet of platform area. A car will make from 1½ to 2½ miles per hour, so that a battery of six elevators will run from 9 to 15 miles, although very rarely making over 12 miles per hour. With an ordinary car, say from 30' to 35' area, this would mean from 3 to 3½ kilowatt hours per car mile of travel, or say 35 to 40 kilowatt hours for a battery of six machines. Without a battery this would require a 120 kilowatt machine as ordinarily rated, worked at an average of 35 to 40 per cent. load. With a properly constructed battery a 60 or even a 50 kilowatt machine will handle the elevators.

Roughly speaking, a storage battery should be able to stand twice the dynamo rate for from three, to seven or eight seconds, and the dynamo rate for one-half a minute. If it has an hour discharge capacity equal to the dynamo capacity in kilowatt hours, it should be perfectly capable to run the Saturday, Sunday and night service required in an elevator plant without losing more than one-half its charge.

So much for the general conclusions on electric elevators, which are necessarily more or less brief.

To meet the hydraulic machine there was designed and devel-

oped what is now known as the Sprague-Pratt multiple sheave electric screw elevator, following the general lines of a tension hydraulic machine in the matter of rope movement, limit safeties and method of control. The net result has been, that this machine now stands the superior to the hydraulic elevator in that it has its speed and capacity with, if anything, greater safety, and certain advantages in its automatics. On high lifts it occupies less space; it is more flexible in its application, is more economical to operate, and it is more easily cared for.

General Description.—The machine may be described as the combination of two old elements with one new one, with specific safeties and methods of control.

Briefly, it is of the horizontal multiple sheave type, with a traveling crosshead and frictionless nut driven by a screw revolved by a motor directly connected, and governed by a pilot motor and rheostat. The general construction consists of a heavy main beam, carrying the traveling crosshead and the lower screw bearing, with special castings bolted at each end, one carrying the fixed set of sheaves, and the other the thrust bearing, brake and motor. The regulating apparatus is independent and self-contained, and is placed on the wall. From the car to the system of multiplying sheaves, the direct multiplying machine and the horizontal hydraulic elevator are practically the same. The crosshead, however, marks the point of departure in the two types.

In the hydraulic machine, this crosshead is rigidly attached to the end of a rod which terminates in a piston moving in a cylinder having an inside length equal to the lineal movement of the crosshead. This cylinder in the vertical type of hydraulics varies from 30 to 50 feet in length, with from 2 to 12 sheave multiplications, and in the horizontal types the multiplication runs as high as 14, with corresponding diminution of length of cylinder and increase in cross-section. Whatever the gearing, however, the length of cylinder is a function of the car travel. In this electric elevator, the crosshead being moved along a screw, stationary so far as the lineal movement is concerned, there is, with any given number of sheaves—only one variable—the length of screw; and, for all heights above about 100 feet, the electric machine has an advantage in matter of length, which, with increased rises, becomes of great importance.

Looking to the needs of office builings, there has been adopted two methods of rope multiplication, determined by the height of building, and so selected that the length of machine over all, shall not exceed about 30 feet for rises approaching 300 feet actual car travel. From this the length grades down to about 21 feet, so that all rises between 60 and 300 feet can be taken care of with an extreme variation of nine or ten feet in the length of machine, and there is thus provided limiting dimension data of great convenience and utility.

These systems of multiplication I may term direct and indirect. In the former, the entire multiplication, varying from six to ten, is done at the machine, and the ropes lead from the end sheaves over the shaft sheaves direct to the car. A free counter-weight is used, the ropes being fastened to the car frame. In this method, which is that common to all horizontal and to many vertical hydraulic machines, the hoisting and counter-weight ropes have unequal duty; furthermore, the ropes having the maximum bending, travel on the outboard sheaves at the same speed as the car. This last is the case also with all vertical hydraulics. In some of the latter, the counter-weight is carried in the cylinder on the piston, or in the strap, or both, its weight being as many times that of a free counter-weight as there are multiplications. Sometimes both methods are used.

Economy of operation and smoothness of movement, however, are antagonistic in their relations to the amount of counter-weight carried. The best method is probably that used when there is a single multiplication in the shaft, giving a two to one counter-weight traveling at half speed, and carried by all the car-hoisting ropes, as is done for short-rise vertical hydraulic elevators.

For long rises I have adopted a combination vertical and horizontal machine rope practice, giving even a more compact machine, a longer life of ropes, and better counter-weight results. In this indirect system there is a division of multiplication, which, while having the same effect so far as speed of car and length of machine are concerned as a high direct multiplication, has an entirely different result in the wear on the ropes and the amount of counter-weight which can be carried without jumping.

This is accomplished by making one-half the multiplication (6 or 8) on the machine, the ropes, properly proportioned, going thence to the bottom of the counter-weight frame, which has a single multiplying sheave on top. The car ropes go over the shaft sheaves, under the counter-weight multiplier, and back up the hoistway, where they are anchored, giving a car speed twice that of the counter weight. The equalizing chains, used to make the pull of the car with any given load constant at all points of the hoistway, are fastened to the bottom of the counter-weight frame and anchored in the hoistway. The space occupied by this multiplier is only two or three inches more than by ordinary form of counter-weight. A proportionally shorter screw, fewer revolutions, and sheaves of greater diameter, characterize this type of multiplying machine.

This system seems to be the best yet devised for long rises, for not only do all the car ropes do equal duty, both with relation to the hoisting strain and the counter-weight, but the rope wear must be less because of the division of speed and multiplication, the necessity of changing only one-half of the ropes at a time, and the possibility of reversal of the ropes on the multiplying machine to get a new wear. Where space is limited, I use a double decked machine, and in the new Commercial Cable Building, which is to be 21 stories high, the machines will be treble decked, and about 10½ feet in height.

Details.—Turning now to the detail construction and operation of this machine, there are a number of features claiming special attention, each unique in character, and marking a radical departure from all other elevator practice. These are the nut, screw, and thrust bearing, the brake, the motor and the regulator apparatus.

One of the most interesting as well as important features, and, perhaps, the one which has been most frequently attacked, is the nut system. It joins the crosshead of the traveling sheaves by a conical seat. There is no fastening between the nut and the crosshead, the continual weight of the car always keeping them in contact; and the friction at this point, being greater than between the nut and the screw, enables the latter to transmit a straight-line movement to the crosshead when the screw is revolved by the motor, and also to revolve the screw and drive the motor as a dynamo when the mechanical brake releases the screw to allow the car to descend. These are the normal functions of hoisting and lowering. There are several other distinct functions of this nut which will be described in considering the "safeties."

Continuing the line of transmission of power, the only points of contact between the interlocking nut and screw are by a chain of balls which occupy a number of threads, and enter and leave the ends of the nut through tubes which are connected together so as to make a continuous conduit. This is one of the most vital points of the elevator apparatus, and herein lies one of the most potent reasons of its success—the reduction of friction by rolling instead of sliding surfaces on almost all parts under pressure; for not only is the nut so constituted, being in fact a developed spiral thrust-bearing, but the thrust-bearing at the motor end of the screw is taken on balls and the sheaves are carried on ball or roller bearings. This nut being a vital part, its development has been most thorough, and a peculiar treatment of steel which has been adopted renders its surface so hard that the wear is very small, and it is well within commercial limits.

So free is the machine from static friction that it is possible to start the car with a very slight increase of current over the normal hoisting current, providing time be taken so that the work done in acceleration is small to the work of lifting, although that is not the usual practice.

The balls have an average crushing strain of 25,000 pounds each, but the working pressure varies from only 50 to 125 pounds per ball. The nut system is a compound one, for, besides the working-ball nut there is another, called the "safety-nut," to which I will make reference later, keyed to it, and between the two is a powerful spring under compression.

The screw is a forged bar of high carbon steel with a peculiarly shaped thread, the finished screw having a tensile strength of 700,000 pounds. It passes through the clearance hole in the steel trunnion crosshead, which carries the traveling sheaves, then through the nut, and is carried at the outer end by a fixed bearing. This screw is sectioned, being joined to the armature shaft by a cone-seated coupling, secured by a taper gib.

The in-board end of the armature shaft, which is, in effect, the extension of the screw, terminates in the thrust-bearing, where the pressure is taken by about 200 steel balls carried in a bronze guide plate and bearing, by specially hardened steel disks. The thrust of the screw being thus taken up on the in-board end, the strain on the screw is invariably between that end and the traveling crosshead—never beyond this; hence, it is always under extension strain—never under compression, and cannot buckle.

The action of the balls on the screw, which is untreated, is peculiar. They form a path for themselves, partly by wear, but principally by rolling compression of the steel, which finally becomes exceedingly hard, such that the edge of any ordinary machine tool would be turned. The balls themselves wear very evenly. Oblique forms in normal practice cannot exist.

Beyond the thrust-plates is keyed an iron pulley, connected by a flexible coupling with the motor shaft. The function of the brake is that of locking the screw when at rest, it is not a means of varying the speed. In case of accident, it has the additional function of helping to stop the screw. It may be described as a compound electro-mechanical brake. A steel brake band, wood-lined, is anchored at one end, the hoisting-side on the motor-bed frame, and the other end is continually pulled down by a powerful spring under compression. The mechanical movement in opposition is through the medium of a peculiar magnet. It is operated by a dual circuit, one in hoisting, another in lowering. In the event of failure of current for any reason, or too high a speed on the down run, this magnet releases the brake in the latter case by a snap switch, operated by an adjustable Pickering centrifugal governor driven by the main screw—and the brake

band promptly grips the brake wheel softly yet powerfully.

Motor.—The motor, which is of the multipolar type, is carried on the same casting which contains the thrust-bearing. The field magnets are of steel, and are excited by two circuits; one, known as the shunt circuit, being variable in strength at will, so as to vary the maximum speed of the machine, and the other, a series circuit, which acts to strongly compound the field. This type of elevators is differentiated from all other electrics by the fact that the action is like that of the hydraulic, for it always works against gravity. In hoisting, the motor takes current from the line, but in lowering, its main circuit is cut off from the line, and the motor, rotating in an opposite direction, is driven as a dynamo by the weight of the car. A strong element of safety exists in the fact that the current in the field coils is never reversed, and consequently the machine is never demagnetized. Hence, under certain conditions of the operation of the safeties, it has a power of self-excitation which is of importance.

The armature which turns in this field is of the ironclad type, and not liable to injury of any kind. It is mounted on a sleeve, is of the 2-path series winding, has a very large commutator, and, of course, multiple carbon brushes. The field coils can be removed without disturbing any other part.

Control.—Considered in its simplest form, and in connection with its action upon the motor and multiplying machine, without reference to the means of communication between the car and the regulator, this last is a very simple device. It is composed of two parts, each made up of peculiarly shaped iron grids of various sizes arranged in circular form, connected to copper contacts on a slate disc over which passes a heavy carbon brush.

The use of iron castings of a specific composition possesses great advantage over any form of wire resistance, not alone in the matter of cost. They are flexible, they expand in any direction readily, and, as made, they have a resistance of from forty to fifty times that of copper, or roughly, that of German silver. The grids are interchangeable, and any of them can be readily replaced.

One side of the rheostat is for regulation in hoisting, the other for lowering. Instead of moving this regulator by hand, it is operated by a pilot motor wound with a right and left handed field, one or the other of which only at a time, can be in circuit with the armature. This pilot is connected to the rheostat arm by a single reduction worm gear, and is operated either from the basement or the car, according to the position of the "change over" switch, by an "up" and "down" button with an automatic lever stop which normally has to be held by the operator to prevent the pilot returning to a stop position. The spindle of the rheostat arm operates switches co-ordinating in their movement, in turn controlling the magnetic make-and-break circuit switches, the down brake, and also the automatic stop lever switches which limit the pilot movement.

The use of magnetic switches instead of hand control switches not only removes the arcing from the face of the rheostat, but it gives the benefit of instantaneous cut-offs not possible by any other means of control. This, on fast machines, is of the utmost importance, and the practical application is that if a car is on the "up" motion, and an operator, because of carelessness or because of fright lets go his stop handle, the current is instantly cut off, the regulator following to stop, and the car is arrested in the shortest time practicable.

Assuming that the circuit is made for the up movement, it first meets with a resistance sufficient to about hold the car and lift the brake. This resistance is then gradually cut out, the torsional effort of the armature is increased, giving the car an upward movement with an acceleration depending upon the rate of movement of the rheostat arm, and with a final velocity determined by the point at which the arm is stopped. If, while hoisting, for any reason the current is cut off, the torsional effort ceases, the brake instantly comes into action and the car comes to rest.

In lowering, the brake is lifted by an independent circuit, but the armature is first short-circuited on itself, and becomes a most powerful dynamic brake. As the resistance in this circuit is increased, the car runs faster. When it approaches the lower limit of movement, an independent retarding circuit is established, and gradually reduces the resistance. This brings the car to the slowest movement. The pilot movement regulation is, to my mind, an absolute necessity of fast passenger work; and its application, although at first attended with a number of annoying difficulties, is to-day by far the most reliable method of control known.

Safeties.—Of course, the vital question to be considered in any elevator system is that of safety. In that respect, I think, we are amply provided. Safeties may be considered under two heads: First, those on the car, and second, those on the hoisting machine. On the car we use a special centrifugal which is attached to the lower section of the car frame. It consists of two long levers, short-fulcrumed at the sides of the car and operating clamping jaws which run in close proximity to the car rails, but normally out of contact with them. The inner ends of the levers overlap, and in action are pressed apart by a very powerful spring under compression. When out of action, these levers are drawn together, the spring is put under compression, and the system locked by a trigger. Near the trigger is a centrifugal governor, operated by a standing rope, which at a determined speed releases the trigger, frees the levers, and the safeties clamp the rails with a pressure of about 16 tons. This safety can be released from the inside of the car.

In the car, as has already been described, there is an automatic stop contact which operates to bring the regulator to the stop position and the car to rest in case the conductor removes his hand from the controller because of crowding, accident or carelessness. On the hoisting machine there are a number of safeties. One which is perfectly apparent is due to the fact that the crosshead is moved by a screw with a heavy armature on the end of it, which is driven through the medium of a nut by a car of limited driving capacity. The screw itself is of forged steel, under tension and torsion strains, with a safety factor of at least twenty to one.

The hoisting nut, as already described, is hardened by a specific process which makes its wear very limited. In addition to this, there is in the nut system what is called a "safety nut." Normally this is out of contact with the thread of the screw, but it is secured to the hoisting nut, and should any accident happen to the latter, breaking its hold on the screw, this safety nut, the threads of which interlock with the screw's threads to a greater depth than the thread of the hoisting nut, would then take the place of the hoisting nut and securely grip the screw. This would put the elevator out of operation because the friction between the nut and screw would be greater than the friction of the traveling crosshead, and it would act simply as a collar on the screw.

The nut system has in addition another function. Since the hoisting nut is only held from revolving by its friction against the crosshead, when the nut gets to the upper limit of its travel the safety nut meets a solid collar on the screw which stops its travel, causing it and the ball-bearing nut to revolve with the screw, without, however, necessarily stopping the motor, and leaving the traveling sheaves to be stopped simply by the weight of the car.

There is still another function performed by the nut system, that of a slack cable device. If for any reason the car in descending, when of course the nut is driven along by the screw, meets an obstruction, the pressure on the nut being instantly reduced, it recedes slightly, allowing the springs between it and the safety nut to expand, throwing the latter into back contact with the screw threads. The nut system then instantly grips the screw, revolves as a collar, and consequently acts as a check against any marked movement of the crosshead corresponding to a free fall of the car on the ropes. Assuming, however, the condition of a perfectly free release from all operative safeties, there is a limit to the rate of revolution of the screw, and in any event there is a rubber buffer at its lower end which would cushion its stop so as to prevent any injury.

Besides the lower limit switch, which has already been mentioned, which puts an increasing retarding force on the motor, there is an upper limit switch for cutting off the current; this is a self-cleaning lock switch, operating in both directions, and moved by a roll on the crosshead. It cuts off the current in hoisting in the upper limit and allows the brake to come on. On the reverse movement it is automatically closed.

I have already mentioned the governor on the machine, which is called a "monitor centrifugal." This is for operating the brake when running too fast. In hydraulic elevators there is no speed-operated device in case of fast running except the centrifugal on the car, and this is frequently set so much above the normal speed on account of the annoyance of having it operated by a temporary excess, as oftentimes to be useless when actually required. The monitor centrifugal does not throw the machine out of operation, but simply slows it up to any desired speed, and then allows the operator to resume control.

The dynamic action of the machine is made use of in still another way by the introduction of an "automatic choking circuit" and switch operated by the same circuits governing the main brake. It is in constant play and closes the circuit around the armature and its series coils through a rheostat under any of the following circumstances: At each stop from up or down; when running down fast enough to work centrifugal on the machine; on failure of the hoisting current, or on failure of the line current. So positive is the control over the motor, no matter whether it be operating to hoist the car or retard it in going down, that the brake band can actually be removed and the car still controlled, and even with the brake in normal position the change from one position to another can be made so promptly that it will remain inactive.

Such is the machine which has been developed during the past three years, and whose first application in a large battery in the Postal Telegraph Building seems destined to have the same effect on the elevator industry that the plant at Richmond has had on the railway industry. It is only permitted to me, of course, to make the briefest allusion to this, but as illustrating in some degree the extent of this industry, buildings of from five to twenty-one stories in height are being equipped with batteries of from one to twenty-six machines of various types, and the business of a single company employing some two or three years ago a hand-

ful of men, now demands a constantly increasing force already numbering nearly five hundred.

[The paper was illustrated by a large number of lantern views.]

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—MR. F. J. SPRAGUE ON ELECTRIC ELEVATORS.

THE 102nd meeting of the Institute was held at 12 West 31st street Wednesday Evening Jan. 22nd at which a paper was read by Mr. F. J. Sprague on "Electric Elevators, With Detailed Description of Special Types," 150 members and guests being present. The paper was fully illustrated by lantern slides, and the practical operation of electrical controlling apparatus for elevators was shown by a working exhibit of the essential parts on the platform. The paper was discussed by Messrs. Steinmetz, Hill and Leonard but owing to the lateness of the hour further remarks were postponed until the next meeting.

At the meeting of Council in the afternoon the following Associate Members were elected:—E. B. Cunningham, Sup't Fort Dodge Light and Power Co., Fort Dodge, Iowa; C. L. Edgar, Gen'l Manager and Chief Engineer, Edison Elec. Ill'm'g Co., 8 Head Place, Boston, Mass.; Edward A. Evans, Acting Chief Engineer, The Quebec, Montmorency and Charlevoix Railway, Quebec, Canada; W. S. Franklin, Prof. of Physics, Iowa State College, Ames, Iowa; Walter L. Githens, Manager, H. P. Elec. Light and Power Co., 7284 So. Chicago Ave.—residence, 5101 Kimbark Ave., Chicago, Ill.; Zentaro Jijima, Assistant, Wagner Elec. Mfg. Co., 2017 Lucas Place, St. Louis, Mo.; Charles Lemon, Hon. Sec'y for New Zealand for the Institution of Elec. Engineers, Palmerston, North New Zealand; John E. Lloyd, Ass't Chief Engineer, Philadelphia Traction Co.—residence, 2008 N. 18th St., Phila., Pa.; Wm. E. Moore, Electrician and Sup't, The Augusta Railway Co., Augusta, Ga.; George P. Nichols, Partner, Geo. P. Nichols & Bro., Elec. Engineers and Contractors, 1036 Monadnock Build'g, Chicago, Ill; Wm. Bancroft Potter, Engineer Railway Dept., General Electric Co., Schenectady, N. Y.; Edward Andrews Wagner, Electrician, The Mexican International R. R. Co., Eagle Pass, Texas—residence, Coahuila, Mexico.

The following Associate Members were transferred to Full Membership:—Harry Bottomley, Electrical Engineer, Supt. Marlboro Electric Co., Marlboro, Mass.; George W. Gardanier, Electrician, Western Union Telegraph Co., New York City.

Approved by Board of Examiners, Dec. 5th, 1895:—Fred. A. Scheffler, Stirling Boiler Co., New York, N. Y.; Harvey Stuart Chase, Electrical and Mechanical Engineer, New York, N. Y.; Ralph D. Mershon, Electrical Engineer, Westinghouse Elec. and Mfg. Co., Pittsburgh, Pa.; Norman T. Wilcox, Manager and Electrician, Seneca Light and Power Co., Seneca Falls, N. Y.; Samuel Reber, Lieut. U. S. Army, Chief Signal Office, Washington, D. C.; Francis Jehl, Representative, F. Hardtmuth & Co., 60 Liberty St., New York.

NEW YORK ELECTRICAL SOCIETY.

The 171st meeting of the Society will be held at Columbia College, Madison Ave. and 49th St., on Wednesday, the 29th inst., at 8 P. M. Mr. Herbert Lloyd will lecture on "Recent Improvements in America and Europe in the Storage of Electricity." Mr. Lloyd, who is connected with the active management of storage battery interests in this country, has just returned from a trip to Europe, undertaken for the purpose of investigating all the recent work in progress there involving the utilization of stored electricity. Mr. Lloyd has a large amount of interesting and valuable information to communicate entirely new to the American electrical public, and will throw much light on the relative conditions of storage battery development, technical and industrial, in this country and on the other side of the water.

OBITUARY.

FIRST LIEUT. SWIFT, U. S. A.

First Lieut. Swift, of the Ninth Cavalry, United States Army, committed suicide at Fort Robinson, Neb., this month, by shooting himself through the heart. His suicide closes one of the most remarkable careers in the United States Army. From the position of telegraph operator in a small town of Virginia he became a private, corporal, sergeant and lieutenant in the army in as many days as there were promotions. When Gen. Myers organized the Signal Corps of the army, Swift had considerable local reputation as a telegrapher, and to secure his services as an instructor he was enlisted in the corps and promoted from day to day until he attained the rank of Second Lieutenant. After joining the corps and beginning his work as instructor he devoted himself to the study of electricity and telegraphy, becoming one of the most skillful operators that the world has ever known and an author on the subject.

There were a lot of fancy tricks in sending and receiving messages that Swift used to do. One of them was to take two messages at the same time. He could write equally well, and beautifully, with either hand, and could take a message from one instrument, writing it out with his left hand, while he copied another message with his right. He could also send a message with one hand while he received another message, copying it with the other hand.

LETTERS TO THE EDITOR.

AS TO A STANDARD LAMP BASE.

The question of standardizing lamp bases is certainly an important one and should receive the proper attention at an early date. Believing that opinions from everyone interested in such a matter will be a help in deciding a question of this kind the following ideas are presented.

The standard base should be of either the Westinghouse or Edison types;—the extra cost of the Thomson-Houston being the principal factor against its adoption. While there are doubtless more Edison bases in use than other makes yet the Westinghouse bases are very largely used on alternating circuits and the demand for them is certainly a good one. There is one feature about the Westinghouse base which is much in its favor as compared with the Edison. The majority of incandescent lamps are placed in a vertical position but a very large number are placed horizontally and this number is increasing daily owing to the adoption of incandescent lamps for signs and advertising purposes. The majority of lamps used in this way are of the 16 c. p. type. If lamps placed in this position are burned at full candle power the filament soon droops until it finally touches the glass and then it is generally but a short time before the lamp is burned out. Of course this drooping of the filament is easily remedied by using lamps with anchored filaments, but there are thousands of lamps used in a horizontal position which have the ordinary filament, particularly on test boards, where they are frequently subjected to extremely high voltages for a short time.

When a lamp has been burned in a horizontal position for a time, by turning the lamp in the socket the drooping filament can be brought on the upper side of the lamp, thus saving the filament from touching the glass and prolonging the life of the lamp. With the Edison base it is impossible to turn the lamps in this way, as the contact at the base of the lamp is then broken; while with the Westinghouse base this is easily done.

While this feature is in itself a small matter, yet it is worthy of consideration.

RUPERT A. JENKS.

PHILADELPHIA, Jan. 20, 1896.

A TREASURE IN THE LIBRARY.

I cannot too highly praise the position THE ELECTRICAL ENGINEER has placed itself in, in the hearts of the electrical fraternity. I have watched for the past nine years THE ELECTRICAL ENGINEER grow, and value it as a treasure in my library. The issue of January 8th is a high tribute to your ability. The article on the New York local Edison Co. is first class, and I would add that this is the character of reading which appeals to the practical man, and still more of it is needed. Wishing you continued and further success.

ALFRED E. BRADDELL, *Elec. Inspector.*

Underwriters' Association, Middle Dept.,
PHILADELPHIA, Jan. 23, 1896.

THE BEST MEANS OF KEEPING IN TOUCH.

It gives me great pleasure to renew my subscription to your most valuable paper, which I find is the best means for keeping in touch with the constant progress in the electrical arts and science. Allow me to congratulate on the Data Sheets, which have been introduced during the past year, and which mark, in my opinion, a great advance in the history of your paper.

HENRY J. SAGE.

ROCHESTER, PA., Jan. 20, 1896.

MOST COMPLETE DESCRIPTION EVER READ.

The January 8th issue of THE ELECTRICAL ENGINEER contains the most complete description of a central station I have ever read; and not only is it interesting reading but a collection of data on one of the most extensive plants in the country, that would probably never have been systematically brought together but for the efforts of your paper. I have already ordered extra copies. Accept my congratulations with wishes for your continued success.

GANO S. DUNN, *Elec. Engr.*

CONTENTS.

A BILL TO VACATE PATENTS.

DURING nearly every session of Congress for the past fifteen years, attempts have been made to repeal all the statutes relating to the granting of patents by the United States, or to so modify them that the present rights of inventors would practically be legislated out of existence. These attacks on our patent system have almost invariably, we regret to say, come from the farmers and "grangers" who have felt aggrieved because they have had to pay a small royalty on apparatus, without which their crops could neither have been sown, raised nor harvested, yet who would deny recognition to the inventor who has not only benefited them directly but millions of his fellow men besides. Having made but small progress in the past in legislation intended to wipe the whole patent system out of existence, the enemies of the present patent law have hit upon another plan, which, under cover of giving the inventor some compensation for his work, nevertheless deprives him of the legitimate fruit of his efforts. An example of this is the Bill (H. R. 281) introduced by Mr. Lacey into Congress, which we here reproduce.

A bill to enable the United States to terminate and cancel letters patent for inventions in cases of general public importance.

Sec. 1. Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That any letters patent of the United States that may be hereafter issued to inventors may be terminated at any time by the enactment of a special Act or special Acts for that purpose, and from the date of the taking effect of such special enactment or enactments all rights under such letters patent shall cease and determine.

Sec. 2. That no letters patent shall be terminated under the provisions of section one of this Act unless a grant of not less than twenty-five thousand dollars nor more than one hundred thousand dollars shall be made in such special Act to compensate the inventor or his assignee or assignees for the loss of such patent: *Provided*, That Congress may further grant an allowance to any inventor, in the case of thus terminating a patent, for a sum equal to the amount expended by such inventor in perfecting his said invention.

This bill came up before the Committee on Patents to whom it was referred and Mr. Lacey himself spoke in support of it. It seems that his whole argument was against the "telephone monopoly," but those who spoke in defense of the patent system as it stands had no difficulty in showing the weakness of Mr. Lacey's position. If the view taken by the mover of the Bill be accepted, the Government, in order to be just, ought to guarantee something to those whose patents they do not take, or who cannot get them worked or introduced. A bill similar in its purport to that printed above was introduced some years ago by Mr. Hall, before his appointment as Commissioner of Patents, limiting the inventor's compensation to $25,000, but it was killed in committee. A similar fate probably awaits the present bill which, if enacted into a law, would practically amount to the confiscation of the inventors' rights. Nevertheless it would be well for all interested in patent property to address a word of protest to their representatives in Congress and thus put an end to a most pernicious measure.

But, that legislation, though of a different nature from that attempted as above, would be salutary for our present system of issuing patents is not to be denied. The weak points therein are well shown by Mr. W. C. Dodge, in an article printed in this issue, and to them is largely due the odium in which the system has fallen in some quarters. Section 4887, which has deprived American inventors of

large sums, rightfully due them, ought also to be stricken from the statute books or so modified that American inventors may not be punished for taking out foreign patents. Bills with these ends in view will, we understand, be shortly introduced into Congress, and inventors and manufacturers should unite in securing their passage.

LESSONS OF THE BICYCLE SHOW.

ANYONE who visited the great bicycle shows in Chicago and New York, particularly the latter which drew more than 100,000 people within Madison Square Garden, must have been impressed with the utter absence of monopoly and the consequent keen and active competition among hundreds of progressive manufacturers and skilled designers. Part of the business may drift later on into monopolistic hands ; but the moment it does the lively public interest will dwindle and the pace of improvement will decidedly slacken. The rate of electrical growth did not drop until grasping hands were extended to control whole sections of the industry, and we do not believe that there will again be rapid advances until the field has been occupied afresh by new concerns disdainful of the old methods and appliances.

A practical feature of the shows was the use of electric lighting. Madison Square Garden was a wonderful sight with its beautiful signs in large and small incandescent lamps by the thousand, many of them with commutating devices run by motor. We venture to suggest to the managers of the coming Electrical Exhibition that they require exhibitors to use electric signs wherever possible. The absence of view-obstructing booths was another element of beauty. The neat iron railings were also to be commended and imitated.

New York is evidently ready to patronize good shows of interest, and we are glad to know that the managers of the May Exhibition are meeting with excellent success in their endeavors to secure attractions of novelty, charm and instruction for the masses.

THE COST OF INCANDESCENT LIGHTING.

WHEN Mr. Edison projected the first incandescent light station it was his aim to produce the electric light at a cost not to exceed gas. That these early attempts did not meet with immediate realization are matters of historical record, but in spite of this fact incandescent light from the very beginning advanced in public esteem in virtue of its intrinsic merit, which consumers have all along recognized by their willingness to pay for. But with improvements in lamps and methods of distribution the cost of incandescent lighting has been steadily lowered until a point has been reached where large consumers can be supplied with profit to the central station, at a figure which puts the electric light in direct competition with gas on the basis of cost solely. As an example of this we need only refer to the rate prevailing in New York City, in which one large customer on the Edison circuits is supplied at .4 cent per lamp hour. These results have been accomplished with a 50-watt lamp and as it is evident that higher economy lamps must inevitably displace those in present use, just as these drove the old 64-watt lamp to the wall, it is eminently timely to inquire just what would be the effect of the introduction of a 37½-watt 16 C. P. lamp, that is, one of 20 lamps to the horse power, with a life equal to that of the one in use at present. Mr. Edison has addressed such an inquiry to Prof. W. D. Marks, whose answer we print in full elsewhere in this issue. Taking the Philadelphia Edison station, carrying 89,359 lamps attached, as a basis, Prof. Marks shows that other things being equal incandescent lighting could be furnished at .43 cent per lamp hour, equivalent to gas at 86 cents per 1,000 cub. ft., and produce 15 per cent. on the invested capital of $2,250,000. These figures are of a most interesting, not to say startling, nature and present an argument and offer an incentive for higher economy lamps which will not be lost. Already 150 and 200 volt lamps have been making gradual headway abroad and we think that in this direction, of high volt, high economy lamps, will be found the solution of the problem which will finally place the incandescent lamp beyond the field of competition with gas, if, indeed, it may not be deemed largely so already. There is nothing so effective in bringing home facts as a concrete example, and Mr. Edison and Prof. Marks deserve the thanks of the electrical community for bringing prominently into view not alone the objects to be striven for, but the profits awaiting the introduction of the 37½ watt lamp.

Apropos to the subject under discussion, we may refer to the description in another column of a high economy lamp in which a niobium filament is employed. It may be argued that the rarity of the metal employed and its seeming high cost of manufacture precluded such a lamp from practical consideration, but we may recall the fact that Mr. Edison spent years and a fortune in quest of the proper vegetable fibre used by him, and also that lamps once sold by him for $1 can now be had for 18 cents, and less.

TELEPHONE, TELEGRAPH AND CABLE.

THE vogue of the bicycle may be marvelous, but to us it seems that the popular use of the telephone is something even more remarkable. The ratio of calls to subscribers averages not less than 6 per day, on the other side of the water, while the average here, we believe, may safely be put, for most places, at 12 per day per subscriber. There is, it appears also, from recent statistics, a rapid increase in this country in the number of subscribers. Seven years ago, the ratio of telephones to population in cities numbering from 40,000 to 100,000 was about 1 to every 200. Now it is said to reach from 1 to 50 and 1 to 100, averaging 1 to 75. Moreover, this increase is likely to be more than maintained. The recent competition in many places has greatly stimulated the use of the telephone, and a factor for development in places like New York, where no competition exists, is the measured system, which enables everybody who really needs an exchange service to get it cheaply.

In this connection, while speaking of telephone growth and prosperity, it is worthy to note that the Sunset Telephone Co. is teaching its operators the art of telegraphy. This may or may not have some relation to the expiration of the American Bell-Western Union contract next November. Meantime, the Western Union Company owing to the steady reduction of its income is understood to have been reducing its force of operators in the larger cities, in some cases to as large an extent as 50 per cent. This diminution of income may also explain the non-issuance of the Company's statement of test office receipts. One item of income, however, ought to be much larger, and that is the one representing the revenues on the submarine cables, due to war scares and crazes. We begin to suspect the cable people and the ammunition vendors of working up a new call to arms whenever the old one peters out.

Telephony and Telegraphy.

THE "KR" LAW AS APPLIED TO QUADRUPLEX CIRCUITS.

BY

ATTEMPTS innumerable have been made in the past to improve the working of the quadruplex telegraph system, which as every experienced telegrapher knows is still far from being a perfect one especially when operated upon long lines. This is because there has not yet been found for its "No. 2 side" a simple receiving apparatus with a sufficiently low "time constant" or requisite degree of delicacy to respond promptly to the first impulses of the current waves which flow to line after each reversal of the sending battery.

The distance to which it is possible to operate successfully a quadruplex circuit with a given potential is, in reality, limited by the electro-static capacity (K) and the resistance (R) of the line: the former factor tending to absorb a portion of every current wave or impulse sent into it, while the latter affects the final strength of the current flowing through it.

The number of signals that can be transmitted per second over any telegraph circuit depends, in fact, upon the numerical value of its capacity in microfarads multiplied into its resistance in ohms, or upon what is known as the "KR Law," which has long been understood to determine the carrying capacities of all our long submarine cables, fast speed automatic circuits, etc., but the applicability of which to quadruplex working has not been so generally known or appreciated.

In telephony this particular law has played a very important part inasmuch as it has rendered possible the calculation of the size of wire required for the successful transmission of speech. It has determined, for instance, that

When KR = 15,000 speech becomes impossible;
" KR = 12,000 speech becomes possible;
" KR = 10,000 speech becomes good;
" KR = 7,500 speech becomes very good;
" KR = 5,000 speech becomes excellent;
" KR = 2,500 or under speech becomes perfect;

so that if a suitable value be adopted as the KR constant for any projected telephone line, it will only be necessary to select the proper kind and diameter of wire, the product of whose capacity in microfarads into its ohmic resistance will give the required standard.

It may here be remarked, however, that the accuracy of the KR law has been questioned with regard to its general application, instances having been cited in connection with the construction and operation of American telephone lines which apparently went to prove that the law is only safely applicable to circuits whose length is within the limits of those by which the rule was formulated. Mr. W. H. Preece who enunciated the formula has pointed out, however, that in the cases alluded to, the value of K was not accurately determined, since the purely metallic character of these circuits exercises a modifying influence upon their electrostatic capacities, or, in other words, reduces the values of K, a consideration that had apparently been lost sight of. Hence the deductions drawn from the measurements made and results obtained in practice (which were quite at variance with the rule laid down), were shown to be based upon false premises, inasmuch as a more correct estimate of their KR values accorded very well with the formula as well as with the telephonic effects observed.

Now since the KR conditions of a line have such an important bearing upon the working of telephone circuits, and as the law pertaining thereto is equally applicable to telegraph circuits, it would seem desirable in the latter connection, that for each of the important systems in use, a KR value should also be found that would serve as a standard for determining their working capacities and the distances through which these systems could be worked direct.

In the absence of any data bearing upon the subject, the following may be interesting as affording at least an approximate idea of the efficiency limitations imposed by the KR law as applied to quadruplex working in one particular instance.

Some time ago the writer was called upon to make a test over the Western Union lines, of the new 300-pound copper wire (868 miles in length) between New York and Chicago, for the purpose of ascertaining whether, in view of its low mileage resistance, it could not be operated as a quadruplex circuit direct, that is, without the aid of a repeater in circuit.

The test was made under highly favorable conditions, the weather being fine at all points along the line, while the inductive interference from neighboring wires was comparatively slight, owing to the particular day and hour of making the experiment. The type of instrument used on the "No. 2 side" was that known as the Freir self-polarizing relay, the potentials employed being 360 volts at Chicago and 320 volts at New York. The value of Chicago's current was 19 milliamperes from the "short" end; and 57 milliampres from the "long" end; the latter developing in the New York instrument an amount of magnetism considerably in excess of that ordinarily obtained in practice, inasmuch as the average full working current on a quadruplex circuit does not exceed 45 milliamperes.

Despite these favorable conditions, and notwithstanding the fact that the apparatus was adjusted to the highest degree of delicacy at both ends of the line, it was found impossible to secure satisfactory working signals on the No. 2 side when the distant polechanger was in operation. The effect of the "reversals" upon the second side relay, cut down its working margin to an extent never before observed in the writer's experience, a result which apparently demonstrated that the advantage gained by the new wire in respect of its low mileage resistance, was more than counterbalanced by the detrimental action, arising from its increased inductive capacity.

It would appear in fact from the distance involved and the amount of surface exposed, that the absorptive properties or condenser-like action of the conductor had increased in much greater ratio than the resistance of the wire had been decreased, and as a consequence the current waves became unduly retarded. This retardation was sufficient in amount to prevent the No. 2 relay—after each "interval of no current"—from becoming energized with that rapidity and intensity necessary to counteract the tendency of its retractile spring to open the armature and thereby mutilate the signals during the aforesaid "intervals," or periods when no magnetism is created in the receiving apparatus.

With a view to determine as closely as possible the KR conditions of the circuit, measurements were taken which showed that K = 13.4 microfarads, and R = 2,682 ohms, thus making KR = 35,938; a numerical value so much in excess of that of the regular successful quadruplex circuit as to clearly account for the difference in results obtained.

When the circuit was divided and repeatered at Pittsburg, there was no difficulty whatever in operating all four sides of the system, although in this case the full strength of Pittsburg's current did not amount to more than 41 milliamperes (16 units less than that received from Chicago), which current, however, afforded a margin amply sufficient to allow of a considerable range of adjustment on the No. 2 side without affecting the quality of the signals during the distant reversals.

The KR value of the circuit under these altered conditions was estimated at about 10,500, so that the following results may be said to have been fully established: (1) an excellent working quadruplex circuit when $KR =$ 10,500. (2) An impracticable working quadruplex circuit when $KR = 35{,}938$; and between these two values are of course to be found the good, bad, and indifferent grades, as well as the limiting figures representing the successful working quadruplex circuit.

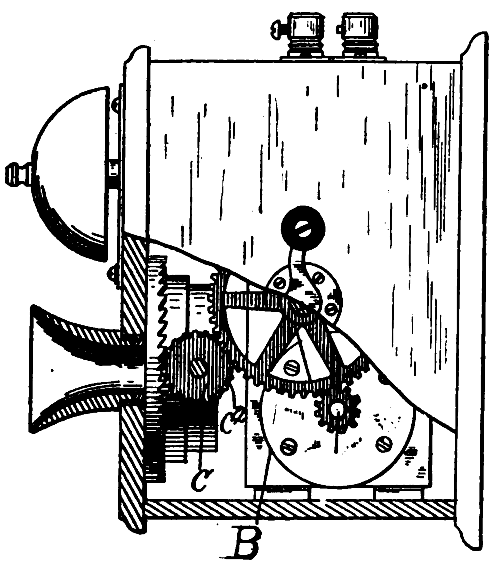
According to the KR law, the speed of a current wave through wires of the same length varies inversely as the product of the inductive capacity and the resistance of their conductors. In wires similar in all respects except length, the speed of a wave in each, is inversely proportional to the squares of their respective lengths, so that the carrying capacity of a wire of a given length, ought to be four times as great as that of a similar wire extending through twice the distance.

As a matter of fact the actual working capacity of a circuit divided in this way is not strictly in accordance with this rule, for reasons that need not be discussed here; but the application of the rule nevertheless affords a clear indication of the advantage of repeatering a long telegraph circuit, the KR value of which will only be that of its longest section.

From these and other considerations, the adaptability of the law to ordinary telegraphy will at once be apparent, and it may reasonably be inferred that the determination of the KR constants for aerial telegraph lines would prove as advantageous in this particular branch of electrical science as in those of telephony and cable working.

THE DINSMORE NON-PACKING GRANULAR CARBON TELEPHONE TRANSMITTER.

MANY devices have been applied to prevent the packing of the carbon in telephone transmitters, which interferes seriously with the efficiency of the apparatus. A novel method of obviating this difficulty is that adopted



DINSMORE'S NON-PACKING TELEPHONE TRANSMITTER.

by Mr. S. A. Dinsmore, of Chicago, whose arrangement is shown in the accompanying engravings.

As will be noticed the receptacle holding the carbon is provided with a toothed rim, which gears with a wheel driven by the handle that operates the magneto-call. Thus it is evident that when a call is sent to the exchange the transmitter capsule is rapidly revolved and the carbon shaken up and redistributed. In this way permanent packing is avoided.

RUN DOWN BY TELEPHONE IN THE BURDEN DIAMOND ROBBERY CASE.[1]

ONE of the cleverest bits of rapid transit detective work ever done in New York City was performed on Saturday, Jan. 4, by Detective Sergeant Evanhoe of the Central Office, Mr. I. Townsend Burden, Manager Schultz of the Thirty-eighth street office of the Metropolitan Telephone Company, and half a dozen others, including telephone operators, shop keepers, and policemen. The funniest part of it all is that the operators, shop keepers, and policemen hadn't the faintest idea that they were assisting in the detection of a man supposed to be the possessor of all or a part of the $65,000 worth of diamonds recently stolen from Mr. Burden's house in Madison square. Most of them didn't even know why they were doing what they did, and they wouldn't know to-day except for this story.

The telephone played the principal part in the arrest that was made, and the wires did their duty well, for by means of them a man at a telephone in Fulton street, was first identified by a man who hadn't the faintest idea why he was identifying him, and then arrested by a policeman from the Old slip station, who was equally ignorant why he was arresting him. And it was all done, too, in less than four minutes, under orders from another man, who sat at a telephone in the Holland House at Fifth avenue and Thirtieth street, and directed the entire affair.

Mr. Burden, who had been getting on an average a dozen letters a day since he advertised a reward for the return of his diamonds, got among other similar missives, a typewritten letter, which sounded so plausible that he resolved to pay some attention to it. It was written on Irish linen paper, and the top, probably a business letter head, had been torn off. The letter was simply addressed to Mr. Burden, and the writer said that he had observed Mr. Burden's advertisement for the return of his jewels, but had refrained from writing before because he could not consent to have any dealings regarding the stolen property unless the $5 000 reward was raised to $10,000. He knew exactly where the jewels were, he said, and was the representative of the men who had them, and who would return them for $10,000. The letter, which was well put together, wound up as follows:

> Of course a man in my position cannot agree to meet you or to see you anywhere. I do not hesitate to say that I do not trust you, and I want you to understand that this is positively the only letter I shall write to you. However, I have a scheme by which we can communicate with one another, and I hereby lay it before you for your consideration. Advertise in the personal column of any New York paper at any time during the next few days a telephone number where I can ring you up, mentioning the time and date when you care to hear from me.

There was no signature to the letter, but it sounded so well that Mr. Burden summoned Detective Evanhoe, who has been working on the case from the beginning. The more the two thought about the matter the more convinced they became that this latest correspondent was serious in his offer and really knew something about the whereabouts of the stolen jewels. Detective Evanhoe wanted to fix up a scheme to arrest the man, but Mr. Burden hesitated. He finally agreed, however, to let Evanhoe do his best to get at the mysterious correspondent. It was understood, that if there was anything to connect the man with the robbery of the Burden mansion Evanhoe was to lock up the man.

This was the state of affairs when Mr. Evanhoe began racking his brain for some scheme by which to catch the man. As a preliminary this advertisement was published:

> $10,000 reward for recovery of the property taken from 5 East 26th St. on the night of Friday, Dec. 27, and a liberal reward will be paid for information leading to the recovery of the property. Parties can communicate in confidence with the owner and no questions asked.

Evanhoe went down to the headquarters of the Metropolitan Telephone Company, at 18 Cortlandt street, explained matters to the telephone people, and asked them to help him out. The telephone people hesitated for a time. It wasn't their business to do detective work, they said, although they were ready to admit that the language of a recent law required them constructively to assist, if necessary, in the work of justice, when called on. Besides while it is an easy matter to trace a line ahead to any point in the system, it might take hours to trace one back after the plugs had all been pulled out, and might necessitate the ringing up of hundreds of operators. The telephone people explained all this, but Evanhoe pleaded that it was the only chance he had to get his man, and finally enlisted them on his side. The telephone people undertook to do their best, and it was finally agreed that Mr. Burden should insert an advertisement in a Saturday morning paper, telling his correspondent to ring up telephone 1,765, Thirty-eighth street, which is one of the Holland House telephones, at precisely 8 o'clock. There is another telephone at the Holland House, not two feet away from the first one, and by means of this latter telephone it was hoped to trace the man who would be talking to Mr. Burden. Manager Schultz of the

1. Abstract from the *New York Sun*. The story told in that paper is here given substantially but has been revised with the assistance of the Metropolitan Telephone Co., in order to make it correct technically, certain parts of exchange and trunk line operation not having been familiar to the clever reporter who prepared the narrative.

Thirty-eighth street central telephone office was let into the secret and advised as to the part which he was to play in the execution of the plan. Mr. Burden went to a newspaper office, where he inserted the following advertisement, which appeared on Saturday morning:

CALL up telephone number seventeen sixty-five 1765 38th St., Saturday, afternoon Jan. 4, at 3 o'clock sharp.

At 2½ o'clock Saturday afternoon Detective Evanhoe and Mr. Burden met at the Holland House, where the telephones were held open for them. A few moments before 3 o'clock Mr. Burden entered one closet and the detective the other, and then all waited anxiously for the tinkle of the bell which would indicate that the man with the secret of the whereabouts of the Burden diamonds had seen Mr. Burden's advertisement. Just as the big clock in the hall of the hotel was at its third stroke the bell in Mr. Burden's closet buzzed. He clapped the receiver to his ear, and a second later was conversing with the man who had sent him the letter.

By previous arrangement, Manager Schultz, at the Thirty-eighth street exchange, was on the qui vive, and by a signal from Detective Evanhoe learned that Mr. Burden was talking with the man whom it was desired to locate. Schultz inquired at once of his operators, in the usual "monitor" way: "Who has 1765?" and "What trunk?" The answer was "42 Cortlandt." Schultz cut through to Cortlandt and inquired who was talking on that particular trunk. He was told "2840"—Cortlandt, of course.

It only took about four seconds for Schultz, running his eye up his numerical record, to see that telephone 2840 Cortlandt was in the store of Lewisohn Brothers, dealers in metals at 81 Fulton street.

He at once gave Evanhoe the location and immediately connected him with Police Headquarters ("30 Spring") who through their private telephone system (which connects all precincts direct with Headquarters) communicated with the Old Slip Precinct; so that the moment the mysterious caller was located policemen were detached to arrest him.

While Evanhoe was talking to Headquarters and Burden was holding the man at the telephone, Schultz made a hasty examination of his "geographical list" and found that there was a pay station at 74 Fulton Street, number 3629 Cortlandt, in a cigar store kept by J. H. Fahrenholz. This station he called up and requested Fahrenholz as a favor to go over at once and see who was using the Lewisjohn telephone and identify him if possible. This Fahrenholz hastened to do while Schultz held the wire. Fahrenholz crossed the street, took a look at the man, returned to the telephone and reported to Schultz in but little more time than it takes to tell it. Schultz was gratified at the successful working of his by-play and reported in turn to Evanhoe.

The man at Lewisohn's telephone was now getting uneasy and when Mr. Burden could hold him no longer, he and Evanhoe flung themselves in a cab and hastened down town. In twenty minutes they were in Fulton street and pulling up in front of 81. Evanhoe jumped from the cab before it stopped and ran inside to find a pale-faced young man secure in the custody of two bluecoats. Gathered about were the Messrs. Lewisohn and a half dozen clerks. They were remonstrating with the policemen, who couldn't explain what they were holding on to the young man for, but who nevertheless refused to let him go.

"Did you get him at the 'phone?" asked Evanhoe.

"I did that, sir," replied one of the policemen.

In a few words Evanhoe explained things to Mr. Lewisohn, and then he learned that the young man was a clerk in the store. He was taken into Mr. Lewisohn's office, where he at first denied that he had ever had Mr. Burden on the telephone, or had ever spoken to him at all. When confronted with the fact that he was caught at the telephone, he admitted that he might have been talking to Mr. Burden or almost anybody. He had seen the personal notice in the paper, he said, and had rung up the number as directed, because he had a cousin living in the West who had once said to him that when he came to New York he would advertise a telephone number for him to ring up. The young man was very much excited throughout the interview, and denied that he had ever written a letter to Mr. Burden. The paper in the office, however, was found to correspond exactly with that on which Mr. Burden's letter was written and the typewriter print agreed in the same fashion. But threats and pleadings failed alike to make him confess.

He wouldn't explain his presence at the telephone in any other way than as above. There was a consultation between Mr. Burden and Detective Evanhoe as to whether the young man should be arrested and it was finally decided not to take him in custody. The Lewisohns were also asked not to discharge him, and the man at last reports was still working in the Fulton street store.

Detective Evanhoe was pleased over the successful working of his scheme, but not quite satisfied with the final result. He thought that he surely had the Burden burglar, or at least a man who was connected with the crime and could be forced to give information which would lead to the capture of the right man. He isn't by any means sure yet that he hasn't got a clue.

THE PROPOSED SUBMARINE CABLE CODE.[1]

THE decision that after January 1, 1898, the European government telegraph companies will refuse to receive any messages not made up of words contained in the vocabulary of 250,000 words published by them in 1894, and the strong probability that the American companies will adopt the same rule, have been the causes of a good deal of opposition among merchants, opposition which is likely to continue until the question is finally disposed of one way or the other. Especially, perhaps, in America, where the question has thus far been less fought, will there be a hard conflict between the companies, possibly aided by some of the merchants on the one hand, and on the other many business firms which think their interests will be seriously hurt by the innovation.

In New York the attitude of a considerable body of merchants has already been expressed. The New York *Journal of Commerce*, for instance, last April published a long editorial attacking the system. Beginning with an admission that the innovation was probably needed, and that the avowed purposes with which it has been started—to lessen disputes, decrease error, and prevent dishonesty—are good ones, that journal contended that the new vocabulary increases rather than decreases the dangers and difficulties of code transmission. It then called for official action by the various exchanges, demanding a thorough revision of the code, and for individual protest as well, to be made promptly, since such a revision will need a long time.

The objections which were made in this article, as well as those which have been made in other protests to be mentioned later, are essentially the same as those brought forward in a communication which the *Evening Post* has just received from a member of the China and Japan Trading Company of John Street, in which the writer says:

"The objections raised against the compulsory use of this vocabulary are upon two grounds. Under previous regulations of the conference codes were permitted made of words, having not more than ten letters, taken from eight designated languages. Subject to this, codes have been built up at the expenditure of enormous labor and great cost, many of them containing 300,000 to 400,000 words. To wipe these out, and compel the use of a much smaller number of words with which it is impossible to make an adequate commercial code, is an act of injustice and oppression.

"The 'official' vocabulary is full of glaring faults which threaten endless confusion and inconvenience in actual use. The compilers of the vocabulary were evidently without experience, and their work has been aptly described as an elaborate blunder from beginning to end. In their preface they state that they 'took care to be entirely independent of preëxisting works of the same kind,' which is to say that they deliberately disregarded all previous experience, that the excellent codes which had been published and which merchants had compiled were all to be set aside as things of no value, and that there is to be put in compulsory use a code which neither in extent nor in quality can meet the requirements of business. In this vocabulary, in which all the words ought to differ from one another 'by at least two letters, and by three elementary Morse signals' (I use the words of the preface itself), are to be found innumerable errors and inadmissible words, such as:

Words identical in signals with other words.
Words with only one signal difference from others.
Words with only one letter difference from others.
Words differing from others by prefix only.
Words with first letter signals dangerously like others.
Words representing names of articles of commerce.
Words representing days of week and names of months.
Words representing coins and measures.
Words representing numerals.
Words representing names of places and districts.
Words representing names of firms.

"The consequences to merchants of being compelled to use this vocabulary will be so serious that action is being taken by commercial bodies in all parts of the world, and great pressure will be brought to bear upon the coming conference to have the action of the last revoked, or very considerably modified."

So important is this matter thought to be in England that in November one of several communications on the subject printed in the London *Times* filled over two columns. This was from the Secretary of the London Chamber of Commerce, who says, "We know that the British commercial world, which forms the immense majority of code users all over the globe, is strenuously opposed to the idea of such a vocabulary. * * * On the sound principle that they who use a commodity are the best judges of their requirements in regard to that commodity, we think that their views as to what they do and what they do not require in the matter of code words should prevail." The Secretary then goes into detail about the vocabulary to prove that the compilers were careless and inexperienced and the official vocabulary unsafe and dangerous. "The main issue, however," he proceeds, "is

1. *Evening Post, N. Y.*

this: after various restrictions and alterations from 1869 to 1879, the present rules were settled in the latter year. They have now been in force for sixteen years; all existing telegraphic arrangements have been founded upon them; and the commercial community rightly claim the prescriptive right to their full benefit."

The London Chamber of Commerce took action along these lines, and a number of reprints from their publications have been during the fall circulated among merchants. The Chamber has also appealed to the Postmaster-General to take action, and has sent requests to Chambers of Commerce in other cities to take a similar course. Some of the foreign and British Chambers of Commerce have concurred in the action of the London Chamber of Commerce. As the matter now rests in England, the government has given an assurance that it is aware of the inadequacy of the code and will carefully consider the advisability of sending a formal protest to the conference of next fall at Budapest, when the matter will be finally settled. Just what steps will be taken in New York cannot yet be foretold. Among the protests already made is one by the New York Coffee Exchange, directing its Superintendent to present the objections to the new vocabulary to the New York managers of the several transatlantic cable companies.

ELECTRIC TRANSPORTATION.

THE AIR-CHAMBER TROLLEY CONDUIT IN VIENNA.

IT has been remarked many times that what are really American inventions have to be introduced into this country from Europe, and another instance of this is now presented. After several attempts and nearly as many failures, our street-railways are now just introducing underground trolley systems, years after Europe had at least two in use,—Blackpool and Budapest. These systems are costly, at least $45,000 per track mile when complete with feeders, etc., owing to their great depth below the surface of the street and the nature of the materials used in their construction. With the slotted conduit with bare conductors, as in the Lenox avenue here, the Metropolitan (9th St.) line in Washington, and other systems, it is not possible to reduce this cost to any material extent.

About August, 1894, an experimental conduit was laid in Germany, near Berlin, which departed radically from the Budapest, Lenox avenue, and like systems,—which rely on the great size of the conduit to keep water, snow and ice away from the wires,—and brought down the size of the conduit to 7″ x 5″,—outside measurement. These trials were completely successful.

The nature of the new conduit is indicated by its name "air-chamber trolley conduit," and it consists of a slotted conduit made up of sections, the top being formed like an inverted box, with the object of preventing any water in the conduit from extending into this box by virtue of the air in it; the conduit and even the street may therefore be immersed in water, but the air confined in this box keeps the water from reaching the wire which is supported therein.

We noted lately the fact that several lines in Vienna were to be equipped electrically. The bidders were Herr E. Lachmann, who carried through the test of the air-chamber trolley conduit described above. Other bidders were: Adolph Springer, Vienna; Kontinentale Gesellschaft für Elektrische Unternehmungen, Nürnberg; Allgemeine Elektricitäts-Gesellschaft, Berlin; Wiener Bankverien, Vienna; Neue Wiener Tramway Gesellschaft with the Anglobank and Siemens & Halske, Vienna; Bau-Unternehmung Ritschel & Comp., Vienna, with the Union Elektricitäts-Gesellschaft, Berlin; Stadler Stephan, Vienna.

We are informed that Mr. Lachmann was successful in the bidding and that a contract to equip a line with the air-chamber trolley conduit system was awarded him, the line to be finished by April next. If this is satisfactory to the authorities, he will equip all the other lines likewise. The fact that Mr. Lachmann was victorious over such great competitors as those named speaks volumes for the system adopted.

The introduction of the air-chamber trolley conduit it is expected will lead to its introduction here, for it is claimed to be very much cheaper to construct than any of the other systems named above, and works just as well when immersed in water as at any other time. The system, which is the invention of Mr. R. W. Barkley, of New York, was illustrated in our issue of July 6, 1892.

THE MASSACHUSETTS RAILROAD COMMISSIONERS ON ELECTRICITY.

THE railroad commissioners in their annual report to the legislature discuss at great length the use of electric motive power. They consider it in many respects an unsolved problem. The competition of street railroads is reported to be severe.

Experiments on steam railroads thus far tend to show that a sufficient quantum of power can be obtained through the medium of electricity; and, thus far, they have proved nothing else. The question of economy, even in these cases, is still unsolved.

The board even considers that the case of horse vs. trolley on street railroads is unsettled as to economy.

The most efficient and economical use of electric power will be found where there is a considerable and steady volume of local and short-distance travel, which requires or justifies the running of numerous light passenger trains, at short and regular intervals, so that the trains will be constantly and uniformly distributed over the railroad line.

It is admitted that electricity is not suited to the moving of freight traffic, and it is not claimed that it is economically adapted to the moving of long-distance passenger traffic. Its province in railroad operation must, therefore, be, if anywhere, in moving suburban passenger traffic, or short-distance interurban and local passenger traffic, or the isolated traffic of branch and spur lines.

On a branch or spur line, where the present traffic, while not large enough to make steam power profitable, is not too small to be developed into a paying business by a service conducted substantially on the street railway plan of operation, it may be advisable to substitute electric for steam power; on the main lines it is not yet prudent.

Inter-town lines necessarily parallel the railroad lines, and thus become competing lines, not only for suburban, but for inter-urban and inter-town travel; and this competition is more or less sensibly or seriously felt by the railroad companies on various sections of their roads.

The railroads have a right, by any legitimate means, to secure their present traffic and to recover the traffic they have lost. The remedy proposed, a clearly legitimate one, is the electrical equipment of their lines for suburban and other local service.

In point of frequency of service, it is in the power of the railroad to put itself on a par with the electric line, with or without a change of motive power.

As regards the rate of fare, it is true that the railroad might with the introduction of electric power, as it can now, reduce its fares to a level with those on the street car. It is equally certain that it could not then, any more than now, other conditions remaining the same, afford to do so.

However cheap electric power may turn out to be, it will, to say the least, be no cheaper for the railroad than for the street railway. The railroad, moreover, is loaded at the start with a burden of investment from which the railway is wholly free.

The remark sometimes heard that street railway dividends are paid by the passengers who ride on the platforms and steps, is probably an exaggeration. It would be nearer the truth to say that they are paid by the passengers who ride standing up. The railroad could not earn its dividends in this way.

While the introduction of a more frequent service on the railroad would no doubt create returning eddies along the margin of the great stream of short distance travel as it now flows, there is much reason to question whether, so long as the other conditions which have been noted continue to exist, that alone would be sufficient to turn the main current from its present course.

Whatever the diversion of short distance travel, the increase of population and industry which the electric railway will foster and develop along the railroad lines, will still be tributary to the latter in a hundred ways.

BROOKLYN RAPID TRANSIT CO.

The Brooklyn Rapid Transit Company has filed articles of incorporation with the Secretary of State. Its capital is $20,000,000 and it paid as a preliminary state tax, $25,000. The purpose of the company is to "construct, extend, repair, and improve railroads," and furnish motive power. The directors are W. C. Bryant, Horace C. Duval, W. W. Goodrich, John D. Kieley, Timothy S. Williams, and C. L. Rossiter of Brooklyn, E. L. Button, W. F. Creed, Frederick S. Flower, Otto Zarker, Jr., Thomas Renwick, Floyd Vail, and James N. Wallace of New York city. Each director takes one share of stock, the company thus beginning business with $1,300.

MISCELLANEOUS.

CONCENTRIC WIRING.[1]—III.

BY SAM. MAVOR.

(*Concluded.*)

SWITCHES have been greatly improved during the last few years, both in mechanical design and in external form. The clumsy switches, with the ugliness of their porcelain covers embellished by gilt lines or floral decorations, have now nearly disappeared. They are superseded by switches of neat appearance, with suitable metal covers. The working parts of the switches are of a much more mechanical type than formerly, butt here still remains ample room for improvement. There are far too many parts, too many screws, and too many contacts. The practice of dispensing with binding screws and soldering the wires directly to the contact plates should be highly commended. How often one sees the attempt made to secure the ends of conductors —frequently of considerable size—under paltry little cheese- or round-headed screws and washers absurdly too light and inadequate to the purpose! The ceiling rose is also a weak spot in double wiring. There are far too many contacts in it. To begin with, there is the usual crockery base, and upon this base are three little brass plates, with twice that number of brass screws. Each of these six little screws binds to a contact the end of a conductor or fuse, and every screw of them is liable to become loose, and every contact to become oxidized. Where vibration or moisture are present the development of trouble is only a question of time. Do those who so freely erect these little collections of screws and contacts ever consider the harvest of petty troubles and annoyances which will be reaped by-and-by?

We must now pursue our painful path of adverse criticism to the lamp holder. The double-contact lampholder, especially when attached to flexible pendants, is the frequent seat of short-circuit and minor troubles. In this little piece of apparatus there are two contact plates, carrying the buffer springs and the inevitable binding screws. Each of these contact plates must be insulated from the other, and both from the surrounding metal tube. When this is done small space remains for further intrusion. But the flexible conductors are still to be brought in and pinched under the binding screws. Stray strands from these flexibles, where they are not most carefully soldered, are frequently responsible for short-circuits and the melting of many fuses. The risk would be reduced if here also binding screws were dispensed with and the wires brought straight through the insulating disc into holes in the plates and soldered therein.

It is with a sense of relief that one turns from double wiring and all its attendant ills to the simple mechanical and straightforward methods of concentric wiring with an uninsulated outer conductor. So far as the writer is aware, no system of concentric wiring in which both the inner and outer conductors are insulated has ever been used for indoor work. It appears probable that the difficulties in the way of designing junctions, switches, and other accessories which shall meet the electrical and mechanical requirements within moderate dimensions and at reasonable cost, will prevent the introduction of such a system. Two and three-wire concentric cables with each conductor insulated are largely used as mains in connection with two and three-wire systems, but in such cases there is no difficulty in providing junction boxes of adequate size. The only system of concentric wiring which has been adopted for internal use has an uninsulated outer conductor, and it is this system that is known as "Concentric Wiring." It is important that it be clearly understood that concentric wiring is not "single wiring," but is something essentially different. This distinction between concentric wiring and single wiring is necessary, because the two have been frequently confused. No method of wiring merits the title "concentric" which is not consistently concentric throughout. In a concentric system the central conductor must be everywhere surrounded over its insulation by a metallic sheathing of conductivity equal to or greater than the core. The switches and fuses should be in the central wire and enclosed in metal cases. These cases or boxes should be electrically and mechanically jointed to the outer conductor, and so form part of the continuous metallic envelope in which the central conductor is enclosed.

It must be pointed out here that, under the existing Board of Trade regulations referring to the insulation of electric light supply mains, concentric wiring is not admissible where connection has to be made to a source of public supply in this country. This is a matter to which we shall recur, and shall meanwhile consider the question of concentric wiring with regard to installations supplied with current from independent plants. The adoption of concentric wiring is the royal road out of the difficulties and dangers which beset double wiring. It seems to be difficult for those who have been accustomed to devote so much pains to attain good insulation of both conductors to realize that there is no necessity for doing so. The adoption of concentric wiring dispenses with this necessity, and abolishes risks which make a high standard of insulation of both conductors in a two-wire system so desirable. Much misunderstanding and prejudice, due to lack of information, exist with regard to concentric wiring; but there is complete absence of valid objections to its use, and prejudice against it is soon dissolved by an acquaintance with the system.

Some of the fire insurance companies were at one time rather suspicious of concentric wiring, probably because they feared its adoption would lead to the abolishing of their cherished rules regarding the width of fillets in wood casing, etc. The insurance companies are, however, now unanimous in their favorable verdict on the subject, and have recognized the advantages of concentric wiring from their point of view. More extended experience and appreciation of its fireproof qualities must confirm the preference many of them now have for concentric wiring.

It has been stated that, owing to one conductor being already earthed, the liability to complete breakdown of the insulation is doubled. This might be true of double wiring, but is certainly not true of concentric. The outer conductor being already at earth potential, there cannot be any risk whatever of shock or spark being experienced from it. There is thus only one vulnerable conductor, and this, with its insulation, being encased throughout its entire length in the metallic sheathing formed by the outer conductor, is well protected against injury. The consequences of injury to concentric and to double wiring are essentially different. In the case of the concentric conductor, if it should be crushed or a nail be driven into it, the instantaneous result is a dead short-circuit and the melting of the fuse. If the insulation should be punctured and moisture gain access, the distance across the insulation between the conductors is so small that the fault immediately develops into a short circuit, and the spark passes from the centre conductor to the inner surface of the metallic sheathing, and being entirely within the sheathing it cannot communicate fire to its surroundings. Concentric conductors are thus self-testing. Faults cannot endure. They cut themselves out automatically. Or, rather, this is what they would do if faults were experienced: but we never have faults in lead-covered concentric conductors. How different is the case of ordinary double-wire conductors laid in the separate grooves of a wood casing! The casing which is provided for mechanical protection may become a positive source of danger, and may be ignited by leakage across the fillet—a danger which the fuse is powerless to prevent. In concentric wiring there is only one cable to handle instead of two, and this carrying its own protection the necessity for wood casing is abolished.

Perhaps the most conspicuous advantage of concentric wiring is that it may be so easily and so effectually made waterproof. The cables may be enclosed in lead sheathing laid under or over the outer conductor, and hermetically sealed to the various apparatus into which the cables are led. This must appeal to all those who have had a varied experience of wiring. If moisture—the arch enemy of good insulation—can be permanently excluded, it means the permanent maintenance of a high standard of insulation, and consequent freedom from trouble.

The next important advantage to be claimed is the large reduction in the number of fuses. The drastic method of abolishing fuses is to maintain the section of the conductors. This can readily be done in concentric wiring to an extent impracticable in double wiring. Conductors of much larger section may be conveniently and safely led into C. C. lampholders, ceiling roses, and wall sockets, than is possible in double wiring. And thus, by maintaining the section of conductors right into the lamp holders, many of the objectionable fuses are abolished. The fuses when reduced in number are more easily centralized and arranged in groups of standard size. It may be objected that if the number of fuses is diminished a larger number of lamps are affected in the event of a fuse being melted by a short-circuit. This is a very natural objection for one experienced in double wiring to offer. But it has no application to concentric wiring. We never have short-circuits. It is in double-contact lamp holders, and double-wire flexibles, ceiling roses, and the like, that short-circuits occur. Compare a central contact and a double contact lamp holder. A $\frac{7}{18}$ concentric cable may be led into the former more easily, and with greater safety, than two single No. 16 L.S.G. wires or their equivalent can be led into the latter. It is not necessary to lead $\frac{7}{18}$ cables into concentric lamp holders, but the possibility suggests the large margin of safety in favor of the C.C. holders. The difficulty of avoiding mishaps in double-wire lamp holders will be emphasized by the introduction of 200-volt lamps. While on the subject of lamp holders, it may be noted that, there being only one buffer spring in the C.C. lamp holder, and that exactly in the centre, there is less risk of twisting lamps out of their collars while inserting or removing them. Concentric lamp holders, ceiling roses, and such fittings, having only one—and that a central—contact to be insulated, may be made of better mechanical design than where within the same space two contacts have to be insulated, each from the other, and both from the containing case. The benefit of the great reduction in the number of parts can hardly be exaggerated, the liability to derangement is so very greatly reduced.

In regard to fittings, the comparison is again in favor of concentric wiring. The flexible conductors of which the pendants are made are of such large section that they are mechanically strong. The pendant terminates at either end in a screwed brass nipple with insulating plug and central contact—an arrangement which is substantial without being clumsy. No loose strands are

possible. The top nipple of the pendant is screwed into the junction or fitting base, and the nipple at the lower end is screwed into the lamp holder. The brackets are similarly wired to screwed nipples with central contacts. The erection of fittings is therefore an extremely simple operation, and the labor so employed is reduced to a minimum.

The method of concentric wiring is based upon a full recognition of the fact that electric light wiring, in order to be permanently durable and reliable, must be impervious to moisture. So far as the writer is aware, this is the only method of wiring which provides a continuously waterproof metallic sheathing over the insulation from the main switchboard to the lamp holders. The main switchboard has the usual single-pole switch and fuse arrangement, and the board is surrounded by the negative omnibus bar, which receives in sockets attached to it the outer conductors and sheathings of the concentric cables. The main cables—which are lead-sheathed throughout, and are generally armored with galvanized iron wires laid over the lead on a cushion of jute—are carried without break or joint direct to their respective distributing boxes, where the central conductors are soldered to the omnibus bars, and the outer conductors terminate in gun metal sockets secured to the boxes. The distributing boxes are of cast iron or cast brass, enamelled white inside, and fitted with fuses, or switches and fuses, as required. These boxes have close backs and hinged fronts closing upon an india-rubber ring, thus rendering them proof against dust or moisture. The concentric branch cables which radiate from these boxes are under all ordinary circumstances of uniform section, namely, 7/21½—equal in area to 0.005 sq. in. The outer conductor of the cable has the same section of copper as the core, and the whole is enclosed in a solid drawn tube of lead. Wherever a joint is to be made, or the cable led into a switch or fitting base, the centre wire is soldered to its contacts, and the outer conductor and its lead sheathing are received and terminate in a jointing pocket cast upon the switchbox or junction. The central wire and its insulation are thus enclosed throughout their length in a hermetically sealed metallic sheathing. The section of the branch conductor 0 005 sq. in. is carried into every switch and into every lamp-holder, no reduction being made. There is no necessity for any fuses other than those in the cast-iron fuse boxes, and these are all uniform and interchangeable. It is very rarely that occasion requires any departure from this plan. Many large installations have been carried out on the lines indicated, some of these amounting to several thousands of lamps, where only two sizes of fuses—main and branch, respectively uniform and interchangeable—have been used. The simplicity and reliability of such a system must be too obvious for emphasis.

The branch cables are led through buildings like flexible gas pipes, but they are not liable to damage as composition gas pipes are. The conductors and the insulation within the lead sheathing serve as a backing for the lead, so that it is not at all easily damaged. It has been the custom of the writer's firm for years to have their concentric conductors and joints embedded in the plaster of new buildings, and they have never known a single instance of a fault developing in conductors so treated. It is sometimes objected that where the conductors are so buried they are not accessible. They certainly are not. Why should they be? It is essential that wood casings carrying ordinary double wiring should be accessible; further, it is desirable that they should be visible wherever possible. But the conditions with regard to lead-covered concentric conductors are entirely different. Given a conductor and joint of imperishable materials, and impervious to moisture and the acids found in plaster and cement, and no reason remains for laying conductors on the surface, or for providing access to them where enclosed in plaster. This demand for accessibility, and the objection to cover conductors with plaster, is a relic of the times when india-rubber-covered conductors laid in wood casing were embedded in walls. The bitter experience which rapidly follows this practice results in the prejudice against covering any conductors with plaster. If anyone wishes to have his conductors laid on the surface of plastered walls, by all means let him do so, but there is no necessity either to lay them on the surface or to provide access to them where lead-covered concentric conductors are used. Access to the distributing boxes only is necessary.

Another bogey is the chance nail driven into the plaster. Consider how largely the practice of embedding composition gas pipes in plaster is in vogue, and how immeasurably greater is the danger resulting from the piercing of such a pipe than from piercing the insulation of a conductor. Yet how seldom one hears any objection to the practice! If a nail is driven into a concentric conductor the immediate result is an emphatic short-circuit, and the fuse melts; there is not the slightest danger. Two cases only of nails piercing embedded conductors have come under the writer's notice. Both of these were in the same building—a block wired for about 500 lights, where all the conductors were embedded in plaster. The faults—one behind a picture moulding, and the other behind a dado—were readily localized, and repaired before the work was completed.

The insulation resistance of the wiring in a new building is not a matter which causes any anxiety. The lead sheathings and brass junctions and switch boxes make one independent in this regard. In occupied buildings the lead-covered branch conductors may be led about under floors and behind plaster and linings with the greatest freedom and complete immunity from danger. The amount of lifting of flooring and disturbance to woodwork and plaster is only a fraction of that required for the carrying out of wood-cased double wiring. The junctions employed may be manipulated by any intelligent man who can use a soldering bolt. No careful lapping of insulating material around the joint is required. The insulation is air space, and there is none better. The branch conductors are of uniform size—so are the junctions—and men soon become expert in jointing. The operation is so very simple and easily performed that it may safely be done by unskilled labor. This feature specially adapts the system for export. As an illustration, it may be stated that a squad of Hindoos, chiefly tinsmiths, under the guidance of one European, carried out in the most satisfactory style the wiring for 3,000 lamps in 10 weeks. In mills or factories floored with wood the conductors are cleated to the woodwork with brass cleats; and where iron beams and concrete floors are met, the conductors, with junctions (tapped to receive the pendants) attached at the proper intervals, are secured by brass or copper cleats to stranded steel suspending wires strained between eye-bolts attached to the walls. The laborious plugging of the concrete ceilings, with the resulting dust and disturbance to the work of the factory and expense to the wiring contractor, is entirely abolished. In single story weaving sheds, ironworks, or other buildings with iron roofs divided into bays, the same method of suspending the conductors between the beams or tie-rods is adopted.

In support of the claim that this method of wiring is reliably waterproof, the case of Messrs. Nobel's Explosives Company's West Quarter Factory may be cited. The buildings to be lighted are isolated and scattered over a large area in order to reduce the risk and minimize the effect of explosions. The regulations issued by the Home Office regarding electric lighting were so very stringent that it was impracticable to comply with them except by the use of concentric wiring. With concentric wiring everything was made easy. Its waterproof and fireproof properties overcame all the difficulties. Every joint and every yard of the conductors is outside and exposed to the weather, cleated for the most part to the gangways. The switches, of cast brass, and distributing boxes, of cast iron, are also all outside, protected only by watersheds. The work of wiring was completed more than three years ago, and, notwithstanding three years' exposure to the elements in this climate, the insulation resistance is as high as ever. Monthly tests of the insulation are required by the Home Office, and on the 10th of last month the insulation resistance was two and a half times higher than the most stringent of the fire office rules require for *indoor* wiring. In the nitrating department of the same factory, which is a quarter of a mile distant from the other installation, the insulation is equally satisfactory, although the wiring is subjected to the profuse fumes of nitric acid. It is noteworthy that the insulation of the wiring at both these places is not india-rubber, but is fibrous. The exclusion of moisture is therefore solely due to the lead sheathing and waterproof nature of the joints.

The more difficult the wiring of a building appears to be, the more favorable is the comparison to concentric wiring. The iron roofs, concrete floors, moisture, and other ills that vex the spirit of the double wirer, have no terrors for his concentric friend. For wiring in any situation, from collieries to boudoirs, where difficulties of erection have to be faced, or in situations where the conductors, &c., after erection must endure excessive heat or cold, moisture, acid vapor, or inflammable dust, concentric wiring meets the case. Conviction of its immense superiority is immediately impressed by inspection of buildings so wired. The thing requires to be seen to be appreciated. Concentric wiring has this further advantage—that a very simple and easily followed set of rules can be framed which are applicable to wiring to be carried out under widely differing conditions.

Contractors who are unacquainted with concentric wiring are often ready, when they know it is in competition with their double-wire tenders, to pour into the ears of their prospective client a dismal tale of the woes which would follow the adoption of any system which would not embrace their precious wood casing and crockery ware. If those contractors were informed on the subject, they would learn how great is their error. Take a contractor who has had experience of concentric wiring into any building whatever, and he will show how to make a better, more mechanical, reliable, and durable job, and generally at less cost, than is possible with double wiring. Those who have used only double wiring, and know no other, are reluctant, and with reason, to depart from practice in which their patterns are systematized and standardized, and in which their staff are trained. But when the change proposed is all in the direction of simplicity and reduction of labor the chief objections to its adoption are removed. That fires or minor troubles are not more frequent in badly-wired buildings is a fine testimonial to the safety of electric light wiring, but is no excuse for the continuance of slipshod work or adherence to existing methods where improvements are possible.

For mining work concentric wiring is specially adapted. The mechanical nature of the fittings, and the ease with which they and the conductors may be made waterproof, are important features. A

concentric cable for mining purposes is more safe than two separate cables. A fall of material from the roof may rupture one of two conductors, and if current is passing the inevitable result is a spark at the point of parting. In fiery mines this might have serious consequences. With a concentric conductor, however, the fall would crush the outer conductor in upon the core, and so cause a dead short-circuit and melt the fuse before the cable parted. The spark would thus take place at the fuse at the pit bank. In the only case of such accident within the writer's experience the fuse promptly melted. Several devices have been proposed for the purpose of preventing a spark at the point of rupture of cables used in pit work. There is room for doubt as to the likelihood of these devices performing their functions in case of need. There can be no question that the concentric cable is much more simple, and it is probably more reliable than any of them. Further, none of these arrangements afford to the miner the immunity from personal danger from shock which the concentric cables does. An E.M.F. of 500 volts is frequently used for such work, and it is usually considered that such a pressure, although sufficient to give a disagreeable shock, is not dangerous to life. That this feeling of security is not well founded is unfortunately proved by recent fatal accidents. For power transmission in mines an ideally safe system is furnished by concentric cables with earthed sheathing, and switches, fuses, and other appliances enclosed in cast iron cases, also earthed, and, if need be, enclosed-type motors with their casings earthed.

With regard to the wiring of ships, it is well known that an essential condition of durable wiring is that it shall be waterproof throughout. The British Admiralty for years tried all that the best materials of the usual double wiring sort, and most careful workmanship, could do to secure the desired result. But the incessantly recurring faults and derangements drove them six years ago to abandon wood casing and the ordinary rubber insulated conductors, and no longer to attempt the impossible. At the time indicated they discarded wood casing, and adopted in lead sheathing of the conductors the most effectual means of rendering them permanently waterproof. It was not, howerever, till four years later that they fully faced the question of making the wiring systematically waterproof throughout. Cast-brass distributing fuse-boxes, and cast-brass switch-boxes, all of waterproof patterns, were then adopted, and means taken to make watertight joints between these boxes and the lead conductors. The present patterns of distributing boxes, &c., although they serve their purpose, are still capable of improvement, and their awkward styles admirably illustrate the difficulty of designing waterproof fittings for use in a double-wire system, where the two sides of the circuit must be insulated from each other, and both from metal of the containing boxes. The Admiralty still adhere to double wiring owing to fancied danger of compass disturbance from concentric wiring. In the early days of electric lighting some of Her Majesty's ships were single-wired, and had dynamos of unsuitable types injudiciously placed. The results were compass disturbances. (The risks of compass disturbance, even from single wiring, are as nothing when compared with those which may arise from the dynamos.) The navigating officers naturally became alarmed, and the alarm has not yet subsided. That well-arranged concentric wiring has no effect whatever upon the compasses of a ship has been proved by the most careful tests. The waterproof qualities of concentric wiring and the safety from fire which it ensures peculiarly adapt it for use on board ship. The history of the development of electric light wiring in our navy is highly interesting and instructive. The conditions to be endured by wiring on board ship are admittedly severe, but it is under these circumstances that the inherent defects in a system will be most rapidly disclosed. We may profit by the experience of the Admiralty, and accept their progress as an index to the direction in which wiring practice on shore should be improved. The same defects which led to the abandonment of double wiring in wood casing in the navy exist in this system when applied to land work. The conditions on shore are less trying, and severe treatment less frequent, but the same inherent defects are there, and only await opportunity to develop.

And now with regard to possible electrolysis due to difference of potential along the outer conductor. In isolated installations where the distances are short the question of electrolysis may be dismissed as having no bearing. In cases where the distances are considerable the risk of electrolysis may be entirely avoided by adopting very simple precautions. The first of these—suggested to the writer by Mr. T. B. Murray—is to so proportion the conductivities of the inner and outer conductors that the fall in volts shall be nearly all in the inner conductor; the copper saved from the inner conductor being added to the outer in order to reduce to a minimum the difference of potential between its ends. Another method adopted by the writer is to provide between the outer conductor and its lead sheathing a very light insulation, and to earth the outer conductor only at the distant end. The layer of braiding laid for manufacturing reasons over the strands of the outer conductor before it is passed through the lead press is sufficient for the purpose, as the maximum difference of potential between the outer conductor and the lead is only a few volts.

The risk of electrolysis is greatly over-estimated. The prejudice against earthing the return conductor is largely due to the results of the early American practice of using an earth return for street railway circuits, instead of providing an adequate return conductor. The consequence of this habit was serious damage by electrolysis to gas and water mains. But what were the conditions? In many cases the current was put to earth at the distant points at 50 volts to 100 volts above the E.M.F. of the dynamo negative, and the large currents, amounting sometimes to thousands of amperes, which had to find their way to the earth plates at the power house carried destruction in their path. But disappearance of these troubles has followed efficient bonding of the rails and the provision of complete metallic circuits of suitable conductivity —in other words, the substitution of a metallic *earthed* return for an *earth* return. In dealing with distribution for electric lighting purposes we do not have to contend with such large differences of potential at different points of the system, and the difficulties are not at all comparable with those encountered in street car work.

A three-wire system with the middle earthed, and concentric wiring on each side with the sheathing connected to the middle wire, is an ideally safe and reliable system of distribution. In a well-balanced three-wire system the fall of volts along the middle wire is negligible, and there is therefore no danger of electrolysis. No disturbance to telephones could take place. Stray currents passing between faults in the conductors would be impossible. The positive and negative conductors being each surrounded by an earthed sheathing, no current can escape from them. Leaks in concentric cables will not endure. The distance between the inner conductor and its sheathing being only the thickness of the insulation, a fault develops at once into a short-circuit which is internal to the sheathing of the cable, and the fuse at once comes into operation. But it must be repeated that faults are much less liable to occur in concentric cables than in double wiring. The importance and safety of the self-testing properties of concentric wiring must be obvious. As distributing networks are enlarged and extended, and the number of consumers increases, it becomes cumulatively more difficult to keep up the pretence of insulation. The present supposed insulation of the three wires is a sham, and the sooner we acknowledge it the better. Experience has proved that good insulation of all three conductors in an extensive network cannot be reliably maintained. Then why not face the difficulties, and end them by earthing the middle wire.

The initiation by Mr. Sidney Baynes of the use of 200-volt lamps and 400-volt distribution on the three-wire system has a significant bearing upon this question. That his policy from the supply engineer's point of view is a sound one is beyond doubt, and that it will be largely followed in the near future is certain. But what about the interior wiring? If the attempt is to be continued to maintain the insulation of all three wires, the possibility is introduced of having a difference of potential of 400 volts between one of the wires and earth. The danger from leakage across damp woodwork and the like is therefore much increased, and possible danger to life introduced.

Recent developments and experience demand the reconsideration of this question of earthing in its relation to electric light conductors. The Board of Trade have issued regulations referring to the use of uninsulated conductors for tramway and railway work. The time is ripe for the framing of regulations relating to an uninsulated middle wire in the three-wire system of distribution.

ARE PATENTS USELESS?

BY W. C. DODGE.

In The Electrical Engineer of Nov. 20, 1895, I noticed the interview of Mr. Rufus R. Wilson with Mr. Edison, in which the latter is represented as saying in a general way, that his patents while profitable to others, have cost him more than he has realized from them; and that in most cases he would advise young inventors to not take out a patent.

Mr. Edison has taken out more patents than any other man in the United States if not in the world; 541 that I know of, and perhaps more; and his inventions have undoubtedly worked greater changes and produced more wonderful results than those of any other one inventor. For these reasons I entertain for him and his remarkable genius the most unbounded respect and admiration, although I have never enjoyed the pleasure of his personal acquaintance.

But notwithstanding my great admiration of him as an inventor, I cannot agree with him in his views as to the uselessness of patents, or that his patents have not paid him more than they cost him.

While it may be true that some of his patents or inventions have cost him as much or more than he sold them for, yet is it not equally true, that all he has he owes to his patents?

As has been told time and again, he was without means when he began, and it is generally understood that he is far from being poor now. How and where did he obtain his wealth, if not from his patents? "From the business," he may reply, built up by himself and associates all over the country. Admit it, but how would he have induced others to engage in and build up that business but for his patents? He ought to know, as we all know, that it was the hope of protection by his patents that induced capitalists and business men to invest their money in the working of his

inventions. Had he not patented his inventions no such results would have been secured and he would have been to-day a comparatively poor man, beyond doubt.

As I am informed, his magnificent laboratory, supplied with material and means such as no other inventor ever had, and by which with the aid of his assistants he was enabled to conduct his endless experiments, was built with money derived from the sale of one of his earlier patents.

The patent office records show that up to August, 1895, he had assigned to the General Electric Company, in which he is largely interested, no less than four hundred and two patents!

Others of his patents he has sold to the Western Union Telegraph Co., while his magnetic separator, phonograph, kinetoscope and other inventions have all been patented and sold or used.

It therefore seems clear that his patents have not proven useless to him, and that so far as the resulting business is concerned, he should rejoice that he did patent his inventions.

On the other hand, Mr. Edison has much reason for complaint of the manner in which some of his patents have been treated by the courts; and it is this I apprehend, that makes him feel aggrieved, and led him to say what he did as to the uselessness of patents.

But he should see, as others have long seen, that the remedy for this is not in decrying patents or the patent system, which I contend has done as much if not more for the growth and prosperity of our agricultural as well as our mechanical industries, as the tariff ever has. It is the genius of our inventors, spurred on by the hope of gain under a patent, supplemented by the skill and versatility of our people that has built up the nation from its infantile condition in 1776 to what it now is, the richest nation on the globe.

To realize what our patent system has done for us, one needs to go back and see what our condition was in the Colonial days, when the so-called "Mother country" suppressed every species of mechanical industry, and when, as Lord Chatham said, he "would not permit the colonists to make so much as a hob nail for themselves!" But all that is foreign to the present subject, and besides it would require a volume to do the subject justice. The remedy for the ills of which Mr. Edison and many others justly complain, is two-fold: First, there should be a complete reorganization of the Patent Office bureau. It is like a man trying to wear the clothes that fitted him when a child. They are too short at both ends, split up behind and down in front.

The Patent Office should be separated from the Interior Department and made an independent bureau. It is much larger now than the entire Department was when first established in 1848.

Then, and for years afterwards, the Agricultural Bureau was attached to the Patent Office. Now that is a separate Department, with its own building, and its head a Cabinet Officer, simply because it is in the interest of a large mass of voters. That is supported by large appropriations from the National treasury, while the Patent Office pays its own expenses and adds about $150,000 per annum to its surplus fund, which on July 1, 1895, amounted to $4,566,757.73.

It is crowded out of its own building, for the erection of which over $360,000 was taken from the patent fund. All this is simply because the inventors constitute but an insignificant fraction of the voters of the country, and have no political influence. They are scattered, one here and another there, over the country, so that, aside from a few like Edison, Brush and Bell, whose reputations have become world-wide, not one member of Congress in twenty knows a single inventor in his district, and the manufacturers, nine-tenths of whose business is built on patents, devote all their efforts to the tariff, and none to the protection or perfection of the patent system.

The Patent Office should be given the possession of its entire building, and should be permitted, as formerly, to use enough of its own funds to provide it with all the help and facilities necessary for the prompt and proper transaction of its important duties.

It should be removed wholly from political influence, and a Commissioner appointed solely upon the ground of his knowledge of, and qualification for the business, with a salary that would command the best talent, and he should be appointed as United States Judges are, for a long term up to a specified age, or during good behavior.

Examiners should be selected who have a practical knowledge of the arts to which their classes relate, should be paid a salary sufficient to secure the most competent men, and should be required to serve for a specified number of years, so as to prevent the early resignation of the ablest men as soon as they have learned the business, thereby leaving the least ambitious and competent, resulting necessarily in "the survival of the *un*fittest."

Second, there should be established a special court for the trial of patent causes, to whom all appeals from the Patent Office should also be taken direct from the Examiners-in-Chief, the Commissioner, with the multiplicity of his other duties, not having the time to wade through the testimony and hear arguments in interference and other appeal cases.

That court, which was recommended by Commissioner Leggett, and subsequently favorably reported by the Judiciary Committee of the House, should be composed of able men who possess a knowledge of mechanism as well as of patent law, so that they could decide cases understandingly and promptly, and with some uniformity by which both the public and the Patent Office could be guided with some degree of certainty, and not, as now, having a court in one circuit deciding one way, and another, another way, and the various examiners following one decision, and another, another decision, thus creating confusion among all parties interested.

This, of course, is but an outline of what should be done, and which it will take years probably to accomplish. If now Mr. Edison and the companies using his inventions, together with other manufacturers, instead of spending their time in complaints, will but unite and bring but a fraction of the influence to bear on Congress on this subject that has been on the tariff, we can have these matters arranged as they should be. When that is done, the grounds for complaint will be removed, and the American patent system rendered complete, and more effective for the protection of inventors and the benefit of the country than it now is, great as its present benefits are.

ECONOMICAL RESULTS IN MODERN ISOLATED ARC LIGHTING.

BY F. E. DRAKE.

MUCH has been said and written about economies which might be practiced in isolated lighting plants, but as yet very little actual data has been presented to the public bearing upon the cost of operating an isolated arc lighting plant, and showing what might be done with modern machinery if properly installed and then operated by careful and competent hands. The plant which is the subject of this paper is that owned by J. L. Hudson, the successful clothier, and lights his handsome store in Detroit, Mich. It was purchased in 1891 and installed under the direction and advice of well-known authorities on electrical and mechanical engineering of the University of Michigan.

The steam plant consists of return flue tubular boilers and modern high speed automatic engines, all well placed and equipped with devices and accessories for economical operation.

The electric plant as installed consisted of five "Standard" arc dynamos of 40 lights capacity each, 205 "Standard" double-service arc lamps, and a 200-light direct current 110-volt dynamo wired for full capacity. The plant was formally started September 1, 1891, and has been operated every working day since.

By courtesy of Mr. A. F. Chappell, Chief Engineer, who has been in charge of the plant since completion, an itemized account of the operating expenses has been furnished the writer. The record is in detail for the full period of four years and four months from September 1, 1891, to January 1, 1896. Time and space is too limited to show the detailed record for each year, but for a comparative basis the expense for the year 1895 is given. In the item of repairs on dynamos the $335.44 includes $200 expended in changing one of the 40-light arc dynamos into a 50-lighter.

In arriving at the average cost per lamp the 200 incandescent lamps are computed as the equivalent of 20 arcs. Each arc lamp is adjusted to 50 volts and the dynamos being wound for 10 amperes it will be seen that each arc consumes 500 watts. The following table shows the record of output.

	For 4 years and 4 months.	For 1895.
Arc lamp hours	1,527.538	351,658
Arc K. W. hours	763,769	175,829
Incandescent lamp hours	2,735,766	1,038,836
Incandescent K. W. hours	150,467	57,186
Cost per K. W. hour		$0.03145

In reviewing the cost per lamp for 1895 one will note in the table that the three chief items of expense are $13.79 for labor, $9.71 fuel, and $2.75 for carbons, figures which are quite phenomenal when the output is considered.

Perhaps the most startling figures shown is the extremely low cost of dynamo and lamp repairs. In 1895 the total of dynamo repairs including brushes was $30.85 or $5.14 per dynamo. Can a better showing be hoped for? The 205 arc lamps had repairs to the extent of $85.90 or 42 cents per lamp, which covered all globe breakage. These results are well worthy of emulation and show conclusively that the oft repeated cry of "economy" has been heard and heeded by the owner and operators of this plant.

Instead of giving the lighting plant credit for exhaust steam at its estimated value, Mr. Chappell has made the set off by reducing the depreciation percentage on the engines and shafting, and the interest charges on a sum placed at $6,000, which the owner after several years' experience, testifies to as being fair and equitable.

Every station man may study these results with some degree of benefit to his plant and purse, and we can none of us afford to say, or believe that we have practiced all economies possible in

generating and distributing electrical energy, whether it be expressed in arc or incandescent lights or power.

DETAILED COST OF OPERATING 205 ARC AND 200 INCANDESCENT LAMPS IN THE J. L. HUDSON BUILDING, DETROIT.

AVERAGE IN LAST COLUMN ON BASIS OF 225 ARCS.	For entire period of 4 years and 4 months.	For the year 1895.	Cost per lamp 1895.
Coal	$8,884.19	$2,185.70	$9.71
Carbons	2,979.81	618.00	2.75
Labor	14,012.09	3,102.48	13.79
Water for boilers	452.09	86.00	.38
Soap, soda, mops and brooms	128.76	12 35	.06
Cylinder, dynamo and engine oil	1,004.28	181.74	.81
White waste	165.15	29 82	.13
Incandescent lamp renewals	807 85	110 83	.49
Incandescent wiring	422.50		
Repairs on boilers and furnaces	794 66	311.33	1.38
Repairs on clutches and shafting	41 85	8 31	.03
Repairs and packing for engines	110.26	45.36	.20
Repairs on 205 arc lamps	163.02	85 90	.38
Repairs on 6 dynamos, including brushes	* 335 44	30.85	.14
10 per cent. depreciation on boilers, $2,000	866.66	200.00	.88
2 per cent. depreciation on engines and shafting, $4,000	346.66	80.00	.36
4 per cent. interest on $6,000	1,000.00	240.00	1.07
Total	$32,464.77	$7,328.12	$32.56

PROF. RONTGEN'S PHOTOGRAPHIC WORK.

A SPECIAL dispatch from London of Jan. 25, to the *New York Sun*, says :—Never in the history of science has a great discovery received such prompt recognition and been so quickly utilized in a practical way as the new photography which Prof. Rontgen gave to the world only three weeks ago. Already it has been used successfully by European surgeons in locating bullets and other foreign substances in human hands, arms, and legs and in diagnosing diseases of the bones in various parts of the body. It is almost an old story now in its first features, and these seemingly miraculous photographs are easily produced in many physical laboratories, while technical journals are publishing reproductions in their pages. The fact that only a faint idea has yet been gained of the practical possibilities of this discovery is already proven, and it is difficult to keep pace with the astonishing supplementary disclosures.

The most important of these is the application of the new omniscient agent to metallurgy. It has been found that although most metals are apparently opaque to the rays of this strange light or force, yet any internal defects or lack of homogeneity in them are quickly detected and recorded on the telltale plate. The sensitiveness and accuracy of the negatives in this respect are described as marvellous.

No two metals are alike under this new test. Lead proves to be almost as transparent as aluminum and wood. Hitherto it has not been possible without a complicated process to test the uniformity of structure of metal work, for instance, gun barrels, iron rails, railroad wheels, or to distinguish at sight the different varieties of iron and steel. All this, it is anticipated, will be shortly achievable by the help of the new photography. It is no exaggeration to say that this would mean the complete revolution of many branches of metallic industry, especially in the manufacture of arms.

Exact reproductions have been obtained of inscriptions or relief drawings on signet rings and metallic surfaces. To the great astonishment of the experimenters, it was found that metallic objects exposed to Rontgen's rays show in the photographic reproduction all inequalities that exist in the structure of metals, such as fractures and cavities. This quality theorists recognize as being due to the great sensitiveness of the rays to variations in the thickness. All alloys or composite metals—and most of those used in the manufacture of arms are composite—show on the photographic plate whether they are completely homogeneous throughout and where and to what extent one metal, for instance, zinc or copper in the so-called steel-bronze cannon, has not thoroughly amalgamated with another. Owing to the intensity of the photographic picture obtained by the new rays, carbon is readily distinguished from iron, and hence it will be possible to recognize the quality of iron or steel. The rays will also probably furnish a simple method of control in the Bessemer process.

The inference from the latest experiments is that nothing is absolutely impenetrable to these strange rays. There are only varying degrees of transparency or opacity. Prof. Rontgen took a photograph the other day of a large metal plate which had been broken in various pieces and welded together, and so carefully joined that the lines of fracture were imperceptible under the strongest ordinary light. The so-called X rays made them as plain as day on the photograph.

Prof. Czermark of Graz has succeeded in photographing a living skull without its fleshy integument. The editor of the *Grazer Tageblatt* offered his head for the purpose. When he saw the result he positively refused to allow the picture to be reproduced or shown to anyone except to men of science. It is reported that he has not slept a wink since he saw his own death's head. I have already mentioned the important fact that these strange new rays are incapable of being deflected by lenses or any substance. Prof. Rontgen deduces from this that perhaps the rays move with the same volocity in all bodies and in some all-pervading medium with which the molecules of all bodies must be surrounded. No effect could be observed on these rays by magnetic influence. From which fact Prof. Rontgen argues that they differ from Cathode rays, investigated by Prof. Lenard. To the question what are these X rays, if they are not Cathode rays, Prof. Rontgen brings forward the hypothesis that possibly their existence may be ascribed to longitudinal waves in the ether. The existence of such longitudinal waves, as apart from the transverse vibrations which account for the phenomena of light, has before now, from theoretical considerations, been suspected by physicists, although there has been no experimental evidence yet brought forward to show their existence. If this should, on fuller investigation, really turn out to be the case, and the X rays of Prof. Rontgen are really due to such longitudinal vibrations, a great step forward will have been made in the theoretical conception of wave motion.

There are already several claims that Prof. Rontgen's discovery had been anticipated. The photography of the invisible has been accomplished before, but not, Prof. Rontgen protests, by his method. The most remarkable instance was an experiment by Prof. Zeugen in 1885. He focussed Mont Blanc in an ordinary camera toward evening from the window of a hotel at Geneva. He waited until he could not discern a vestige of the mountain through an opera glass, then opened the apparatus and left the plate exposed until midnight, when he found he had obtained an excellent picture. He explains the process thus :

It is clear that in an electric discharge from mountain tops toward the heavens above them the mountains are negative poles while the clouds represent positive poles. Now, the cathodic light thus produced is too weak to light up the mountain in the middle of the night so as to make it visible to the human eye ; but the strata of ice and chalk embedded in it are excited to lively fluorescence and phosphorescence, and thus are very sensitive to photographic plates, which receive the picture in the darkest night.

THE ELECTRICAL POTENTIALS AND ACETYLENE GAS.

About one hundred gentlemen, including the leading electricians and gas engineers of New England, were in attendance at the monthly dinner of the "Electrical Potentials" which was held at the Quincy House, Boston, Tuesday evening, Jan. 21st. The dinner itself was a decided success as were also the proceedings that followed. The subject for consideration was introduced by Mr. W. R. Addicks, engineer of the Bay State Gas Co., which has recently purchased the rights for the city of Boston and town of Brookline, to manufacture Acetylene gas.

Mr. Addicks read a paper on the new illuminant, in the course of which he related the results of his recent visit to the works of the Calcic Carbide Co. at Spray, N. C.

An interesting discussion followed, the consensus of opinion being that both gas and electricity had little to fear from the advent of the new candidate for popular favor, and that it was more than likely to find its more general use as an enriching medium for coal or water gas.

Seventeen new names were added to the list of "Electric Potentials" before this, the most interesting meeting yet held, adjourned.

MORE PLANS FOR NIAGARA FALLS, N. Y.

The "Model City" which includes large blocks of real estate in the vicinity of Lewiston, just at the outlet of the Niagara Gorge into Lake Ontario, is now being pushed. The company makes the positive announcement that it has made a contract to furnish 25,000 horse-power to a company that will invest $10,000,000 in the manufacture of iron and steel in Model City. It is claimed that leading iron and steel men are in the enterprise, that 5,000 men will be employed and 1,000,000 tons of finished steel turned out annually. It is also stated that steel can be manufactured in Model City $2 per ton cheaper than in Pittsburg. The sites for manufacturing plants will be furnished free and power will be sold for $10 per horse per annum, with 24 hour day. The company will now push forward their canal which was commenced last year to completion. It will be ten miles long, forty feet wide and twenty-five feet deep. So they say.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JAN. 21, 1896.

Dynamos and Motors:—

Alternating Current Motor, M. Hutin and M. Leblanc, Paris, France, 553,469. Filed Nov. 17, 1892.

Object of the invent'on is to construct and operate alternating current electric motors that the torque of the armature or rotating part shall be a constant maximum whatever the speed of rotation may be.

Electrolysis:—

Apparatus for Electrolyzing Chloride Solutions, E. Hermite, London, Eng., 553,464. Filed June 22, 1895.

An anode for electrolyzing purposes, consisting of a glass plate and a network of platinum wires strung on opposite sides of said plate.

Apparatus for Electrolyzing Chloride Solutions, E. Hermite, London, Eng., 553,465. Filed June 22, 1895.

Relates to apparatus of a simple kind for the purpose of electrolyzing chloride solutions for the production of disinfecting-liquid, and automatic regulating apparatus.

Lamps and Appurtenances:—

Art of Manufacturing Electrical Incandescing Conductors, J. W. Aylsworth, Newark, N. J., 553,296. Filed July 27, 1894.

For description see page 111, this issue.

Incandescing Electrical Conductors, J. W. Aylsworth, Newark, N. J., 553,323. Filed July 27, 1894.

Similar to above.

Electric Arc Lamp, E. H. Crosby, Boston, Mass., 553,335. Filed May 27, 1895.

A stage arc lamp with inclined carbons. Relates especially to means for preventing sticking.

Miscellaneous:—

Electric Gas Lighting Apparatus, H. C. Farquharson, New York, 553,304 Filed Nov. 4, 1895.

Similar to patent below.

Electric Gas Lighting Apparatus, H. W. Brinckerhoff, Brooklyn, N. Y. and H. C. Farquharson, New York, 553 330. Filed Apl. 8, 1895.

Device for lighting railway gas lamps by electric spark.

Magnetic Extracting and Separating Machine, F. J. Barnard, J. C. Moore & J. D. Atkinson, Seattle, Wash., 553,446. Filed Feb. 27, 1895.

Details of construction.

Railways and Appliances:—

Electric Railway, W. M. Schlesinger, Philadelphia, Pa., 553,264. Filed Dec 21, 1886.

In an electric railway the combination of a working conductor comprising a series of insulated or disconnected sections, a series of separate feeding conductors for supplying said sections, conductors constituting paths of high and low resistance interposed in said feeding conductors, safety devices in the conductors of low resistance, and return circuit connections opposed to said sections.

Trolley, W. Kaup, Newark, N. J., 553,410. Filed June 7, 1895.

Provides trolley wheel guards in connection with reversible trolley poles; prevents interference of parts such as will derail the trolley and renders the trolley guard automatically adjustable in relation to the poles.

Telephones:—

Telephone Call, J. G. Smith, New York, 553,364. Filed Aug. 17, 1895.

Consists in a main line having a signaling instrument, a magneto or dynamo electric machine located on a normally open spur circuit leading from the main line and means for opening or breaking said main line and introducing said spur circuit, includ ng said magneto, into said main line.

Telephone, S. A. Dinsmore, Chicago, Ill., 553,452. Filed Apl. 22, 1895.

For description, see page 123, this issue.

LEGAL NOTES.

A RULING ON STREET CARS AND FUNERALS.

Judge Brill, in St. Paul, Minn., has filed an order granting the motion of the defendant for a new trial in the personal injury damage suits of Theodore H. Johnson and Sarah S. Johnson against the St. Paul City Railway company. These suits grew out of a collision between Johnson's carriage and a street car at the corner of Broadway and Eighth street last spring. The carriage was being driven in a funeral procession that was crossing Broadway, and the motorman attempted to run the car across the procession, with the result that the carriage was smashed and Mrs. Johnson, the mother of the first-named plaintiff, seriously injured. The case was submitted to the jury on the theory that the city ordinance providing that processions shall have the right of way applied. But Judge Brill has changed this, and grants the new trial. In the memorandum attached to the order the court says:

After further consideration of the question I have come to the conclusion that section 6 of the ordinance of 1869, relating to fast riding and driving of horses in the streets, does not apply to the operation of street cars. At the time the ordinance was passed street cars were not in use in the city, and the ordinance was intended to apply to such vehicles as are driven about the streets and may be moved from place to place at the will of the driver. The person in charge of an electric car does not drive the car in the ordinary acceptation of the word.

Processions upon the street sometimes are of great length, and occupy a considerable period of time in passing a given point, ten, thirty, forty minutes, or an hour or more. An ordinary loose vehicle can turn aside and proceed upon another street without much inconvenience. A street car is a public conveyance for the transportation of passengers. It proceeds upon a fixed track, and could do nothing but wait, whatever the time might be, and such a rule would greatly inconvenience the public. The interruption to a procession by the passage of a car would at most be slight, and frequently there are breaks in a procession through which the car might pass without interrupting the progress of the procession at all.

Of course, without an ordinance the street car has no greater right of passage than the persons in the procession. The company is liable for negligence the same as in any other case, but these cases were tried and submitted to the jury on the theory that the ordinance gave the procession the right of way, and that to run the car through the procession was negligence per se, and hence there must be a new trial without regard to whether, aside from the ordinance, there was sufficient evidence to sustain the finding of negligence upon the part of the defendant.

PERSONAL.

C. C. CALDWELL, E. E., M. E.

MR. C. C. CALDWELL, E. E., M. E., of 327 Elmira street, Williamsport, Pa., informs us that he expects, within the next few weeks, to open a "Manufacturers' Agency" in that city, and has about concluded arrangements with certain manufacturing firms to represent them in central and northern Pennsylvania, especially in the counties adjoining Williamsport. This is an unusually fine field, there being no supply house or agency within a radius of 150 miles. Mr. Caldwell desires to handle on certain business arrangements the products of some good engine company, a water-tube boiler, a good line of electric light and power and railway supplies, and several other articles to be used exclusively in the fields above named.

Mr. Caldwell has had a practical experience of over ten years, in all branches of electric lighting work, and is fully able to make the designs, purchase all the supplies, handle the men and install complete plants. He will make a specialty of looking after all contracts in Williamsport and vicinity. Mr. Caldwell will be glad to receive catalogues and trade lists.

MR. T. J. CARRUTHERS has been appointed manager and electrician of the Falls City, Neb., plant.

PROF. W. D. MARKS has resigned as president of the Philadelphia Edison Co.

MR. GEORGE J. DAVIS, who for the past four years has been electrician for the Alliance, O., Street Railroad Company, has resigned.

MR. ALBERT SCHMID, Chief Engineer of the Westinghouse Co., left for Europe last Wednesday on a vacation which will extend over several months.

MR. E. F. SEIXAS is in New York City in behalf of the Tennessee Centennial Exposition making arrangements for the electrical effects and exhibits.

DR. J. E. LOWES, president of the local Light, Heat & Power Co., of Richmond, Ind., has been appointed surgeon general for Ohio, and has been presented with a handsome sword of honor for state occasions by his friends.

MR. W. BOARDMAN TOBEY of Pittsfield, Mass., who has been manager of the S. K. C. Electrical Supply Company since its organization, has accepted a position as manager of the Ecuador General Electric Company of Guayaquil, Ecuador, South America. He will leave for his new field of operations about February 15.

MR. LAMAR LYNDON has just started for Japan, in which country he will represent a number of manufacturers of standard electrical apparatus and steam engines. His headquarters will be as Yokohama, and he can be addressed care of the Hon. Edwin Dun, U. S. Minister, Tokyo, Japan.

MARRIED.

PLUMMER-WHALEY.

Frank O. Plummer, senior member of the firm of Plummer & Ham, Worcester, Mass., and Miss Maud E. Whaley, were married recently at the home of the bride in North Sterling, Connecticut. The ceremony was performed by Rev. F. M. Houghton, of Putnam, a cousin of the groom. The bride was a former resident of Worcester. The groom is a graduate of the Worcester Polytechnic Institute, class of '94, and is an active member of local Masonic bodies.

Trade Notes and Novelties
AND MECHANICAL DEPARTMENT.

THE AMERICAN CARBON CO.

A notable impression was made at the recent Northwestern Electrical Convention by the American Carbon Co., of Noblesville, Ind., which has the support of large financial interests in Indianapolis, and is in the field as a wholly independent company for the manufacture and sale of the highest grade of carbons. The company has placed itself squarely on record as an anti-trust organization, but is not merely satisfied with making that its war cry and seeking a sympathetic market. It believes that public feeling is with it, in the electrical trade, but it also believes in making and selling the best article, and this is the real point at which all its endeavors have been consistently and persistently aimed. It invites correspondence and orders, and offers the best goods at fair prices.

RUMOR AND DENIAL.

"Reported that friends of Westinghouse have made an agreement with General Electric people by which 150,000 shares of General Electric, 6000 Westinghouse common and 10,000 Westinghouse pfd. are to be put in trust and a business agreement made."

"The report regarding agreement between Westinghouse and General Electric companies is a N. Y. Stock Exchange story and we are authorized by General Electric people to deny it officially."

"Activity in General Electric is on a report that a Boston banker, known to be in friendly relations with the Westinghouse Company, has received an offer of a seat on the Board of Directors. This is regarded by recent Boston buyers as evidence in favor of the report of steps toward a better understanding between the two companies."

THE MAYRHOFER STAGE LIGHTING COMPANY.

The remarkable success achieved by the Mayrhofer Stage Lighting Co. in the equipment of theatres, has made its present shop facilities too small to handle the business, and the Company has therefore made arrangements with the General Incandescent Arc Light Company, of New York, who will in the future manufacture their apparatus. The headquarters of the Mayrhofer Stage Lighting Co. have been removed to the offices and factory of the General Incandescent Arc Light Co., 572 First Ave., New York.

Among the recent installations completed by the Mayrhofer Company is the Valentine Theatre at Toledo, Ohio, and the Mayrhofer stage regulators are going in all over the country. Their remarkable compactness and the fineness of their gradation make them favorites in this line.

The Company have also just secured the contract for the lighting of the Academy of Music, Jersey City, N. J.

NEW OFFICES OF THE STANDARD AIR-BRAKE CO.

The business of the Standard Air-Brake Company has increased so rapidly that it has become necessary to secure larger office space and better facilities. In considering the different buildings adapted to their use, the Company decided that the American Surety Company's mammoth new structure at 100 Broadway would be the most desirable headquarters. A suite has been rented on the tenth floor giving abundance of light and air. The view from the offices is fine and takes in the harbor and river. The removal occurred on the 21st inst., since which date the Company's headquarters have been in the American Surety Company's building. Mr. Wessels says the latch-string will hang out and that he will be glad to welcome old and new friends in the new offices.

WHITTINGHAM ELECTRIC CAR HEATERS.

Recent sales of the Whittingham Electric Car Heaters have been made as follows:—City & Suburban Railway Company, Baltimore, Md., 21 heaters; Baltimore Traction Company, Baltimore, Md., 5 heaters; Second Avenue Traction Company, Pittsburgh, Pa., 12 heaters; Ithaca Street Railway Co., Ithaca, N. Y., 5 heaters; Cortlandt & Homer Traction Co., Cortlandt, N. Y., 2 heaters. Heaters have also been shipped to the following roads: Montreal Street Railway, Montreal, Can.; Belle City Railway Co., Racine, Wis.; Terre Haute Electric Railway Co., Terre Haute; Consumers Electric Lt. & St. Ry., Tampa, Fla.; North Chicago St. Railway Co., Chicago, Ill.; Winnipeg Elec. Street Railway, Winnipeg; Bloomington Street Railway Co., Bloomington, Ill. An extract from letter recently received from Mr. D. Thomson, Supt. of the Ithaca Street Railway, Ithaca, N. Y., says: "We are pleased to note that, so far, we have had so much satisfaction with the use of the heaters that we have no hesitation whatever in saying that they are the best thing in the market, of which we have any knowledge, and it is the writer's opinion, that you should in some way make them more extensively known, and their adoption would surely be more universal. You should particularly impress upon any one using car heaters, the fact that your heaters are clean and sightly, and that the heat is not intense at any one point, but is evenly distributed throughout the entire length of the car. In almost every other heater that is on the market, the exact reverse of this is the case. Then again, with the old style open resistance coil heater, the heat is so intense in some of them, as to not only scorch the seat rugs of the car, but sometimes the passenger's clothing. The heaters in our cars are often taken for hot water heaters, and are a mystery to the passengers, as to how they are heated."

BALL ENGINES IN THE ELECTRICAL FIELD.

The Ball Engine Co., Erie, Pa., make an interesting and suggestive note of work going through their shops, where the engines are intended for the electrical field. The range of use shown is very remarkable:—

A cotton works, three coal mines, a tin plate mill, a large lake passenger steamer, a spinning works, two steel works, a shoe factory, a manufactory of mats and rugs, a car works, a knitting works, a hotel, a wood working plant, a state reformatory, a state insane asylum, an apartment house, two bank buildings, four office buildings, three store buildings, besides engines for electric light and railway power stations. A large proportion of these engines are to be direct connected to dynamos of the standard types, showing the close connection at the present time of steam and electricity.

ADVERTISERS' HINTS.

Micanite was largely used in the De Ferranti alternator at Deptford, England (the armature of which weighs 35 tons), and has given excellent results, having been tested up to 25,000 volts. Micanite is the specialty of the Mica Insulator Co. of this city.

A Gold Medal and Diploma has been awarded to Hanne Bros. at the Cotton States Exposition for the best wire reel. The reels are adjustable and are sent on trial to any responsible party.

The Electric Appliance Co. state that the high grade of Paranite wire has always been maintained, making it of especial value where the conditions of service are severe.

The Sunbeam Incandescent Lamp Co. are again advertising their lamps now so long and favorably known.

The Central Electric Co. call attention to their large stock of telegraph instruments—keys, relays, sounders, batteries—in short everything.

The Beacon Lamp Co.'s catalogue of multiple series, miniature and decorative lamps is now ready and will be sent on application.

John Wedderburn & Co., patent attorneys, of Washington, D. C., invite requests for information regarding their $1,800 prize offer for patentable ideas.

The American Carbon Co. have made it their aim during the past year to manufacture a carbon surpassing all others in purity of light and length of life. They claim to be entirely successful.

NEW YORK NOTES.

The Perkins Switch Mfg. Co., of Hartford, Conn., have appointed Mr. C. I. Hills manager of their sales department, with headquarters at 219 Havemeyer Building, New York City. Mr. Hills has been known for many years as one of the very best lamp salesmen this country has ever produced, and has been associated with the Perkins Switch Co. since they took up the manufacture of incandescent lamps nearly a year ago. There is no more generally popular man in the electrical trade than Mr. Hills, and with the entire management of sales in his hands the Perkins products should become more favorably known than ever before.

WESTERN NOTES.

The Electric Appliance Company has covered the Western States with a calendar that is unique and artistic in design, and contains a Moonlight Schedule that will be found particularly useful to station managers.

☞ *Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.*

THE
Electrical Engineer.

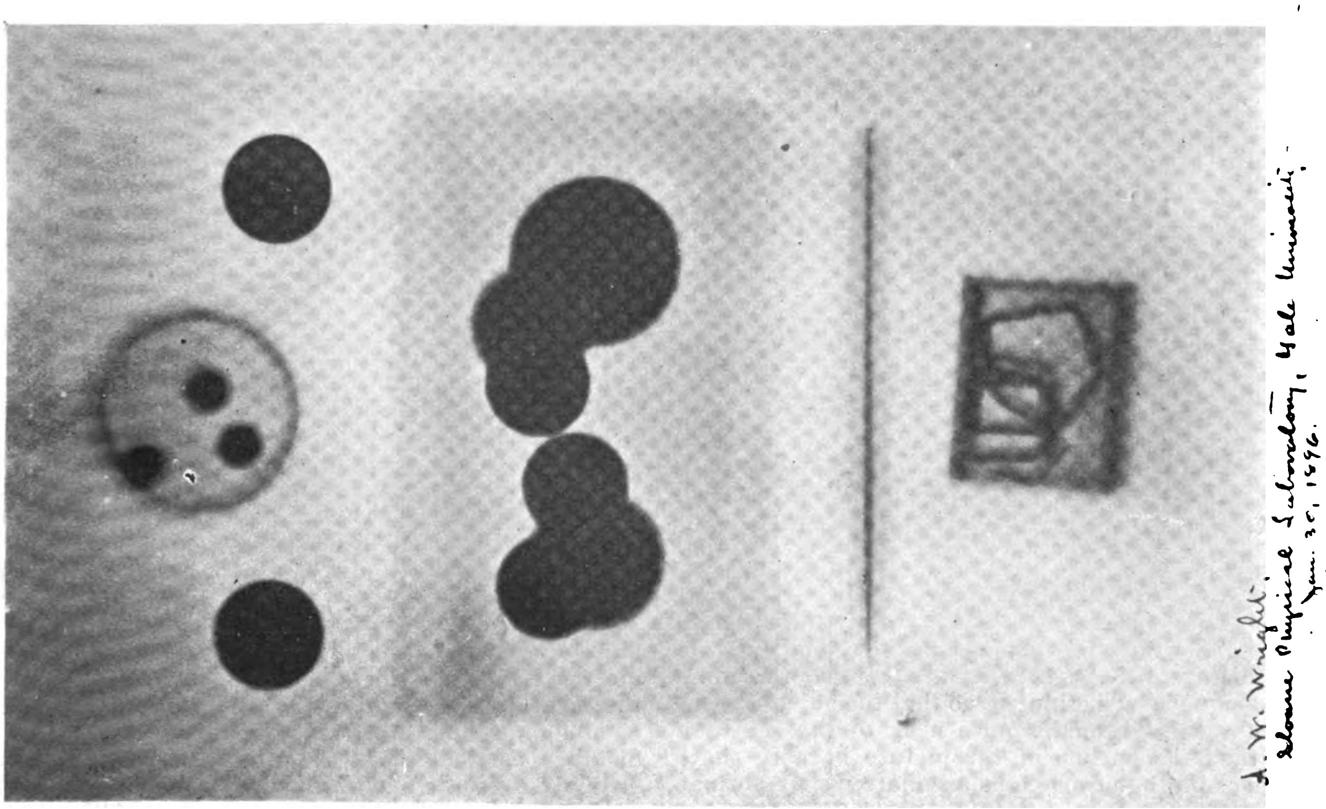
Vol. XXI. FEBRUARY 5, 1896. No. 405.

Electric Lighting.

CATHODOGRAPHS BY PROF. WRIGHT, OF YALE UNIVERSITY.

WE have received from Prof. A. W. Wright, Professor of Experimental Physics at Yale University, New Haven, Conn., a bromide print cathodograph of a number of objects, which we have reproduced in a half tone engraving on this page. Prof. Wright's experiments were made with a great variety of substances, and it was found that strong show the design and lettering on both sides. The two aluminum medals are shown at the left in our engraving, on either side of the three spheres referred to below. Unfortunately the bromide print has not brought out the details of the design and lettering which appear in the original plate. In this experiment the ebonite plate holder constituted the screen between the medals and the sensitive plate.

In other experiments which were made by Prof. Wright with pine board interposed, a closed paper box containing aluminum grain weights left a trace upon the plate which appeared as though the box were almost transparent and the weights themselves some-



Cathodographs obtained With Crookes Tubes by Prof. A. W. Wright, Sloane Physical Laboratory, Yale University, New Haven.

impressions were obtained upon a photographic plate even when it was enclosed in an opaque wrapping of black paper and covered with a pine board half an inch thick. It was evident at the outset that the order of transparency of different subjects for the light rays was very different from that which is found with the cathode rays. Thus pieces of glass were more opaque to these rays than some of the metals or than ebonite, which is perfectly opaque to luminous rays, but transmits the cathode rays with great freedom. Among the metals aluminum is especialy distinguished, and in one of the experiments of Prof. Wright an aluminum medal left its impress upon the plate so clearly as to

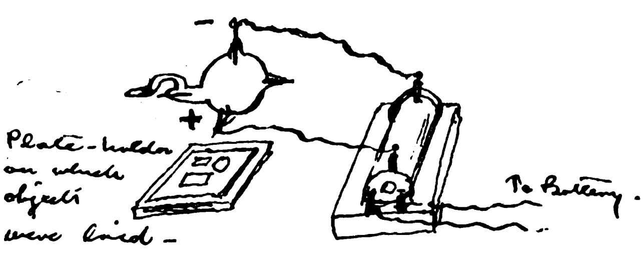
what translucent. This is shown at the right in our engraving. An ordinary lead pencil lying near the box upon the interposed board showed its graphite core by a darker trace in the middle of the fainter impress of the wood of the pencil; seen at the left of the aluminum grain weights.

Another paper box contained embedded in cotton three small spheres, one of platinum, one of brass, and one of aluminum; shown at the extreme left. In this case also the box and the cotton appeared so nearly transparent as to leave but a slight impression on the plate. The brass and platinum spheres intercepted a large portion of the cathode rays, the aluminum sphere

a much smaller proportion. A number of United States coins—silver, copper and nickel—produced strong impressions, showing almost complete interception of the rays, but there were differences, the copper coins transmitting more than the nickel and the nickel more than the silver.

In an earlier experiment a somewhat thinner board of white wood was used, the plate being wrapped in black paper as before. On this board was laid a pocketbook of dark Russia leather with several flaps of leather within, and containing seven cards, two of them thick. A number of coins were slipped into the inside compartment of the book, which was then closed and laid upon the board under the tube. On the plate, when developed, only a faint shading was left by the pocketbook, but the coins left a strong and definite picture, showing with surprising clearness their number and position in the book. This cathodograph is shown in the centre of our engraving. A trace of Prof. Wright's hand, which rested upon the board during this experiment, was also strongly depicted. The outlines of the hand are somewhat blurred, and in the palm faint traces of the passage of the rays between the bones could be detected, but there was little of the effect, reported by Prof. Rontgen, of the greater distinctness of the impression made by the bones.

It will be remarked that the pictures produced on the sensitive plates by these experiments have to the eye an appearance similar to those of shadows thrown by the object upon a surface when the source of light is but a short distance away. If the object is at a



PROF. WRIGHT'S ARRANGEMENT FOR TAKING CATHODOGRAPHS BY MEANS OF CROOKES TUBES.
Autographic Sketch Furnished by Prof. Wright.

short interval from the illuminated surface, the image is somewhat enlarged, also distorted if the rays fall obliquely, and the edges somewhat blurred or diffused. If the distance of the tube is increased or the interposed opaque layer is thinner, so that the object experimented upon is brought quite near to the sensitive plate, then the outline of the picture is more sharp and clear and the proportions are more nearly normal. In Prof. Wright's first successful experiment instead of a photographic plate a piece of sensitive bromide paper was used simply wrapped in stout black paper absolutely opaque, on which the objects were laid, consisting of a pair of scissors, a lead pencil, and a quarter of a dollar. These objects left a strong impression, with remarkably clear outlines of their exact forms.

The reports of Prof. Rontgen's work state that the cathode rays do not suffer refraction, and that therefore no image is formed by the action of a lens through which they pass. Prof. Wright's experiments confirm this, and seem to indicate further that they are not susceptible to double refraction or to reflection. In this respect they are radically different from rays of light, as also from the rays produced by electric oscillations as described by Prof. Hertz.

THE PHENOMENA OF THE CATHODE RAYS.—SUGGESTED APPARATUS FOR THEIR PRODUCTION.

BY

Elihu Thomson

I NOTICE in your valuable journal of the issue of Jan. 22, reference is made, under the heading, "Electric Photography Without Light," to further dispatches from abroad with regard to Prof. Rontgen's work. It occurred to me in this connection that it would be proper to point out the fact that the discoverer of the phenomena of the cathode rays in penetrating opaque bodies was Hertz, and that to Phillip Lenard was due the discovery of the fact that these cathode rays, which Hertz had demonstrated could pass through aluminum shut up in a vacuous chamber, might also pass through aluminum when it was made a part of the enclosing vessel. In this case the rays projected from the vacuous space, passed through the aluminum and into the air, or into the media beyond.

Lenard showed that these rays could penetrate a considerable distance from the aluminum window in the Crookes tube, and that they were capable of causing phosphorescence in much the same manner as when they fell upon substances within the tube; that they would also penetrate metals and many opaque substances, and were capable of acting upon photographic plates which depended upon the relative opacity to the cathode rays, other things being equal. Lenard also showed that the rays were not only capable of passing through the aluminum from the Crookes' tube, but that they were propagated through a vacuum which was made so high that no electric discharge could pass. In other words, when the rays were set up in the Crookes vacuum by an electric current they might enter a much higher vacuum, incapable of carrying an electric discharge, and traverse such higher vacuum. From this he reasoned that the phenomenon was some effect of the ether.

In the absence of any other information concerning Prof. Rontgen's work it would appear that what he has done is simply to magnify Lenard's experiments and apply the principles in somewhat modified ways. Lenard experimented with a very moderate size of apparatus, energized by ordinary induction coils, and it would not be surprising to find that with larger and more powerful sources of current, producing high frequency waves, passing through a vacuous tube, that the cathode rays would be far more intense and might be able to produce much more pronounced actions at a distance, particularly as the property which they most strongly presented in Lenard's experiments was the photographic property or the power of provoking chemical action on salts of silver.

It would seem, therefore, that it might be possible to construct a cathode ray generator consisting of, say, two flat discs or plates of aluminum held apart by insulation, and the space between which is connected to a high vacuum chamber. It would then only be necessary to attach to the plates the terminals of a powerful apparatus giving alternating discharges of high frequency, to set up in the space between the electrodes or plates an intense play of cathode rays, provided the exhaustion was made proper for their development; which rays would pass outwardly through the aluminum sheets and manifest their presence in the medium surrounding the same. Or, it is conceivable that a vacuum chamber might be con-

structed entirely of aluminum with an insulated terminal contained therein, the space between the terminal and the envelope being exhausted to a high degree, and kept so, while the outer envelope and the one terminal were connected to an electric source in like manner. These constructions would not be very difficult to produce if the need should arise, and, if the statements are true that a considerable thickness of aluminum is still transparent to the rays, there must be scarcely any limit to the intensity which might be given to them, while if heat was developed in the passage of the discharges it could readily be carried off by cooling media caused to circulate outside the apparatus. The whole subject is one of absorbing interest, and one which may advance our knowledge of matter and ether, and may, besides, give rise to practical results.

The paper of Phillip Lenard describing his experiments, was, I believe, first published in "Wiedemann's Annalen," and republished in the London "Electrician" of March 23, 1894, on pages 574 and 575, and continued in the issues of March 30 and April 6 of the same year.

It may be possible, as has been stated in some of the newspaper accounts of Rontgen's work, that he holds to the opinion that the cathode rays investigated by Lenard are different from those which the former has been working with. Until, however, further details are received which will enable us to judge of the correctness of this view it will suffice to point out the great similarity between the effects of the rays which Lenard investigated and those which Rontgen is now reported to be using.

PHOTOGRAPHS TAKEN BY THE MOORE "ETHERIC" LIGHT.

THE announcement of the remarkable results obtained by Prof. Roentgen in photographing objects screened from the photographic film by various bodies, with the aid of the rays emanating from Crookes' vacuum tubes, has set many to work repeating these remarkable experiments. In line with these we have deemed it of interest and importance to bring before our readers the remarkable results obtained by the employment of the direct lighting effects of vacuum tubes in the photography of objects in the usual manner.

The results heretofore obtained when vacuum tubes have been used as the source of illumination have resulted in comparatively feeble effects and have failed to give distinct and sharp outlines of the object on which the camera was focused, even with long exposures. What strides have recently been made in this field will be apparent on an inspection of the engraving forming the supplement to this issue of "The Electrical Engineer" and also that shown on this page. Both these engravings were made direct, without the slightest retouching, from photographs obtained by Mr. D. McFarlan Moore in his Newark laboratory by the aid of vacuum tubes excited by discharges made with his ether gap break. The photographs were taken in a room 10 by 11 feet in area, with the tubes disposed around the walls; four tubes being used, 9½ feet long by 1¾ inches in diameter. In the illustration on this page one of the tubes was held by one of Mr. Moore's

FIG. 1.—INTERIOR OF DARK ROOM, MOORE LABORATORY, NEWARK, N. J. TAKEN ENTIRELY BY LIGHT OF CORNICE TUBES SHOWN IN PICTURE. FROM UNRETOUCHED NEGATIVE.

assistants. The number of vibrations employed in this instance was 100 per second, and the time of exposure was three minutes.

In order that our readers may fully understand the means by which these effects were obtained it may be well to recall that the fundamental principle employed in the Moore system of "etheric" lighting, as the inventor prefers to call it, consists in generating electric waves or vibrations suitable for producing luminous effects by interrupting the flow of electric current through a circuit of induction in a high vacuum as contradistinguished from a partial vacuum or one in which the rarefaction has not been carried beyond the point suitable for exhibiting luminous effects. The electric waves or vibrations so generated are made to produce luminous effects by acting upon a receiver containing a rarefied gas.

In order to produce etheric or phosphorescent light there is required a high electromotive force with a short wave length. Heretofore high electromotive forces have been obtained by the utilization of counter electromotive force, due to the breaking of a circuit of high induction; but the degree of the counter electromotive force, or the final voltage obtained, as is well known, depends very largely on the suddenness with which the circuit is disrupted.

As may be seen from Fig. 2, in Mr. Moore's apparatus the circuit through the magnet is disrupted at the contact F, placed within the vacuum tube D, the interposing dielectric being, instead of air, which is a comparatively good conductor, a vacuum of almost infinitely high resistance and inserted in the circuit in a minimum space of time.

Another reason for the results obtained is that, as the vibrator is within a vacuum, it is free to move. That is, it has no air resistance and practically it is proved that it vibrates at a rate of three or four times as fast as the same vibrator would vibrate in the open air.

In the apparatus shown in Fig. 2, the light, of course, is produced at R. The vibrator tube consists of a glass tube enclosing a small bit of iron (the armature) attached to a metallic spring G, and in contact with the metallic point F. It is essential that the vibrator tube D should be exhausted to the very highest degree obtainable, while the tube which produces the light R should have a degree of exhaustion which is comparatively low, and which is that best suited for producing the maximum light. The circuit passes through the magnet C, whose self-inductive discharge is thrown into the tube R. The terminals of the tubes

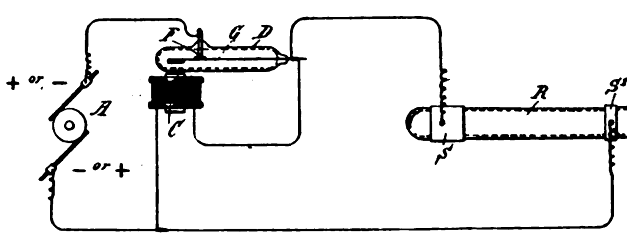


FIG. 2.—MOORE'S VACUUM TUBE LIGHTING SYSTEM.

are coated with metallic paint, and to these coatings are attached the wires. It may be noted that the terminals of the light giving tube can be connected either directly in shunt around the break or around the terminals of the coil.

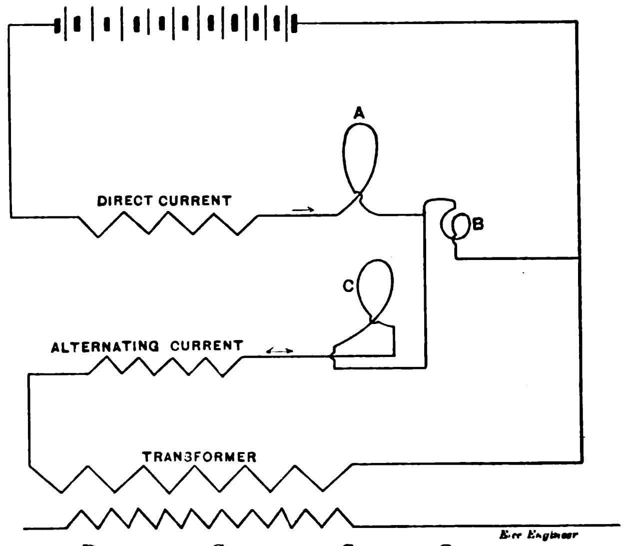
The remarkable clearness of and abundant light shown to be present in the photographs can leave little doubt that vacuum tube lighting has advanced a long way towards practical application in the art of illumination.

In this connection it may not be improper to mention that the Moore Electrical Company has been formed to develop Mr. Moore's inventions in this field. president, Mr. Leopold Wallach, treasurer, and Mr. D. president; Mr. Leopold Wallach, treasurer, and Mr. D. McFarlan Moore, electrical engineer.

A DIFFERENTIAL METHOD OF COMPARING DIRECT AND ALTERNATING CURRENTS.

BY JAMES E. BOYD.

A CONVENIENT method of comparing direct and alternating currents is by means of a dynamometer, on the principle of the differential galvanometer, having a pair of equal fixed coils, one for direct current and the other for the alternating current, and



DIRECT AND CONTINUOUS CURRENT COMPARER.

a common movable coil for both. The fixed coils may be made by winding two wires together. They are finally balanced by connecting in series so as to oppose each other, and adjusting an auxiliary coil until a current sent through them produces no deflection.

They are then arranged for use, as is shown in the accompanying diagram, where A and C are the fixed coils and B the suspended coil. The mean force between a direct current in A and an alternating current in B is zero. The torque between A and B is that due to the direct current alone, and in the same way that between C and B is due to the alternating current alone, and when these are equal there is no deflection on making the circuit..

Where it is not desired to connect the two circuits through B, a double coil may be used. The balancing can all be done on the fixed coils in this case. This arrangement has the disadvantge of requiring four connections with the suspended coil, and is, of course, more difficult to wind than with a single coil.

THE BEST ELECTRIC LIGHT COMPANY, of New York City, has been formed to build and operate conduits for wires, with a capital stock of $5,000. The directors are J. A. Gormack, L. Dexter, and F. B. Jacobus, of this city.

LIGHTING THE ELEVATED.—A bill has been introduced in the New York State Senate requiring the Manhattan elevated to use electricity or gas of 18 C. P. in lighting its cars, and forbidding the use of kerosene or coal oils after June next.

FROM AN UNRETOUCHED NEGATIVE.

ON THE MOTIONS OF THE LUMINOUS GLOW IN RAREFIED GASES PRODUCED BY ELECTRIC OSCILLATIONS.[1,2]

BY J. ELSTER AND H. GEITEL.

In the course of some experiments on cathode rays, in which a high-tension transformer was used instead of an induction coil, we observed in a Lenard tube[3] a peculiar discharge

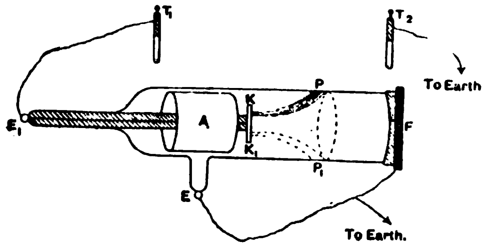

Fig. 1.

phenomenon, the nature of which we endeavored to elucidate by a series of experiments.

For transforming the alternate current of a large induction coil of about 18 cm. maximum sparking distance, we employed the arrangement described by Tuma[4]; the discharge of the attached condenser of large capacity took place between two adjustable zinc terminals, the distance of which in these experiments only amounted to ½ mm. to 1mm, (with larger distances the discharge tube ran the risk of percussion). On joining the aluminum disc K (Fig. 1) with the terminal T_1 of the transformer, while putting the other, T_2, as well as the cylindrical electrode A and the metal cap F, to earth, we observed at a pressure of about 1 mm. the following phenomenon:—

From the electrode K there proceeded a fine light thread KP, bent upwards, which produced vivid phosphorescence both where it originated on the metallic plate and where it impinged upon the glass wall. The phosphorescent patch on the

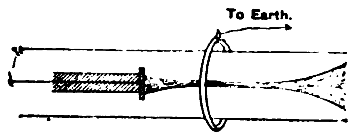

Fig. 2.

(oxodyzed) aluminum disc had a bluish white, and on the glass the well-known green color. Both patches increased in brilliance as rarefaction was carried further, while the luminous thread connecting them steadily decreased in luminosity, and almost totally disappeared at the highest attainable rarefactions. Thus the impression was created of a fine cathode ray, bent upwards, proceeding from the plate K. If a conductor put to earth, say the hand, was brought near this ray from above, it jumped into the position K_1 P_1 (shown dotted in the figure). On passing the hand slowly round, the patch P passed in succession through the positions indicated by the circle P. P. The luminous thread K. P. was always urged on to the opposite side of the glass tube away from the conductor—was, in fact, repelled by it. Insulated conductors acted in the same manner, but much less powerfully. Dielectrics had no effect. The bending upwards of the ray was evidently due to the fact that the discharge tube was rather close to the working bench. The effect of this could be elim-

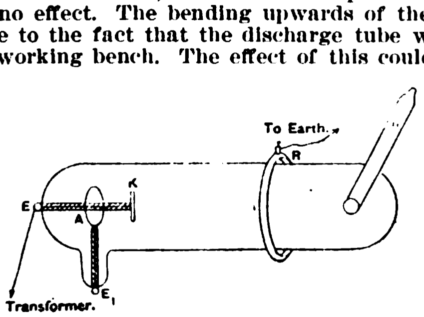

Fig. 3.

inated by placing a metal ring put to earth round the tube. The patch then moved into the center of the plate K, and the luminous ray assumed the shape shown in Fig. 2 without losing its sensibility to conductors approaching from outside.

To follow up the phenomenon further, we now replaced the Lenard tube by a vessel of the shape shown in Fig. 3. In this apparatus the aluminium ring A corresponds to the cylindrical sheet of the Lenard tube, the metal cap bearing the aluminium window having been dispensed with as unnecessary. Exhaustion was carried on while the induction coil discharges passed through the tube until the sparks began to

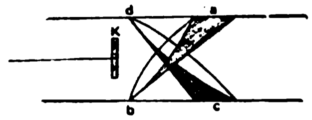

Fig. 4.

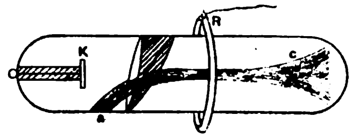

Fig. 5.

pass outside between the terminals E and E_1; then the apparatus was fused off the pump at s.

The connecting tube n served as a handle, being screwed into a wooden clamp. The fusing point s is the most endangered piece of the apparatus. On the approach of conductors sparks are easily produced here which puncture the glass. The ring R, which may be replaced by a thin annular wire, is placed at such a distance from K that the movable discharge is formed in the greatest intensity. Its appearance depends upon the distance between the conductors K and R. With high vacua it disappears completely when the ring R is

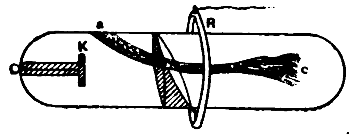

Fig. 6

brought very close to the plate, or is placed in such a position that K lies in the plane of R.

After having convinced ourselves that it was possible in this manner to prepare vacuum tubes which would constantly exhibit the phenomena, we next endeavored to determine the direction of the current in the movable thread of light. For this purpose we introduced such a tube between the poles of an electro-magnet provided with a commutator.

This information would be given by the behavior of the discharge in the magnetic field. For if K (Fig. 4) is a metallic plate from which cathode rays issue normally to the surface, these are not freely developed in a magnetic field; they are deflected like a current thread fastened at one end, and produce on the cylindrical glass wall a phosphorescent patch, which, according to the position of the commutator in the circuit, assumes the position a b or c d. The tube is supposed to be in an equatorial position.

In the first place, the ring R was placed so that the phenomenon shown in Fig. 2 took place; then the electro-magnet

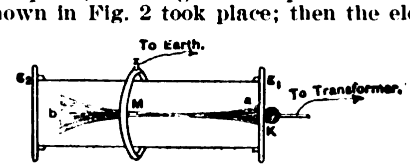

Fig. 7.

was excited. The result was that while the cathode rays proceeding from R were deflected upwards, the phosphorescent patch produced by the movable light thread shifted from the plate K down to the glass wall, or vice versa (See Figs. 5 and 6).

This implies that while the former are due to an electric motion proceeding from K as a cathode, the movable discharge must have its cathode at c, and that the two lengths represent the opposite phases of an electric oscillation. The mobility of the latter may, therefore, be due to the fact that the cathode is not a metallic equi-potential surface, but a plane, in either the glass or the gaseous space, whose position may be displaced by approaching conductors.

In the above experiments the discharges were introduced by means of a metallic electrode. Now we endeavored to simplify matters by using an electrodeless glass cylinder 5 cm. wide and 25 cm. long, the two ends of which were closed by plate

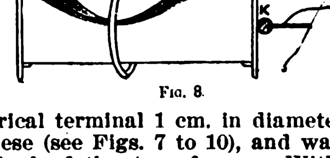

Fig. 8.

glass. A spherical terminal 1 cm. in diameter was in contact with one of these (see Figs. 7 to 10), and was connected with the free terminal of the transformer. With a suitable distance of the ring R from the electrode K, and with a suffi-

[1] *Wied. Annalen*, Vol. LVI., No. 12, p. 733.

[2] Movable light bands and brushes in a vacuum have already been investigated and described by Tesla (*see* Martin, "Tesla's Investigations," &c.), but we have considered the following short description of our experiments to be not superfluous on account of the simplicity of the arrangements, and the conclusion to be drawn from them concerning the nature of the movable discharge.—AUTHORS.

[3] *See* P. Lenard, *Wied. Ann.*, LI., Plate IV., Fig. 1.

[4] J. Tuma, *Wien. Ber.*, 102, Part 2A, p. 1,352, 1894.

ciently high vacuum (0.01 mm. to 0.001 mm. of mercury), there appeared, besides the phosphorencence of g_1, under the influence of the cathode rays proceeding from g_2, a bluish pencil of light at c (Fig. 7), which contracted in the center of the ring M to a narrow band, increasing slightly in diameter from M to a, and producing at a on the glass plate g_1 an intensely green phosphorescent circular patch of about 1 cm. diameter In this case, also, the luminous thread M a was highly sensitive to neighboring conductors. In the magnetic field it assumed, according to the position of the commutator in the circuit of the electro-magnet, the positions shown in Fig. 8

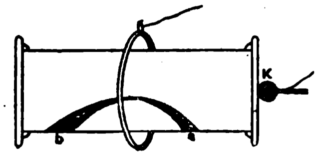

FIG. 9.

and Fig. 9. The phosphorescent spot is always designated by a.

We made sure, by a direct experiment upon a thin copper wire lightly suspended between the poles of the same electro-magnet, and traversed by a constant current, that this band of light behaves to magnetic forces as if it were traversed by a current from a to b. While, therefore, the cathode rays produced by K are directed from g_1 to g_2, as proved by the phosphorescence of g_2, as well as its behavior in the magnetic field, those produced in the movable band of light follow the reverse direction, from b to a.

Here, then, we obtain the same result as with tubes with flat metallic electrodes.

It might be argued that the movable phosphorescent patch is caused by the cathode rays proceeding from K, and reflected by the opposite wall. Although the behavior of the phenomenon in the magnetic field contradicts this view (in Figs. 5 and 6 the cathode rays proceeding from K do not reach the opposite wall at all), we thought better to decide this question definitely. We placed in the electrodeless vessel

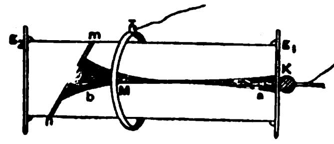

FIG. 10.

(Fig. 7), at an angle to the axis of the tube, an elliptical plane mica plate m n (Fig. 10), which would reflect the cathode rays proceeding from g_1 on to the wall of the cylinder. The discharge shown in Fig. 10 shows distinctly that the thread of light a b is not at right angles to the reflecting plane. The phosphorescent patch at a can, therefore, not be explained by the reflection of the cathode rays from g_1 at th mica plate.

Another conclusion also follows from this. Since cathode rays producing the phosphorescent patch a are not perpendicular to the mica plate m n (as is always the case when such cathode rays are formed at the surface of conductors or dielectrics), it may be assumed that their origin is not at the surface of contact between the mica and the rarefied gas. We are obliged to seek their origin in the gaseous space, and must consider that within the oscillating gas column the (as yet unknown) conditions are fulfilled which determine the genesis of the cathode rays. The gas column which is made luminous by rapid electric oscillations is therefore the origin of the cathode rays, and always produces phosphorescence when it impinges upon the glass wall of the tube. Since its position is entirely dependent upon the capacity conditions of the discharge tube regarded as a condenser—the discharge always going along that side of the tube which has the smallest capacity, and therefore first attains the discharge potential, this column and its cathode rays change with every change of capacity, as produced by the approach of conductors on one side. It always recedes from the conductor, since this increases the capacity on that side of the tube.

If the interpretation of the phenomenon described is correct it will give a further proof for the view of the nature of cathode rays founded by Hertz, Jaumann,[5] Lenard, E. Wiedemann, and Ebert, according to which these are not due to projected electrode matter, but to motions in the ether akin to light.

THE CHICAGO ARC LIGHT IMPROVEMENT COMPANY has been formed by P. Brown, W. G. Adams, and J. H. Miller, with a capital stock of $100,000.

ON THE NEW KIND OF RADIATION.[1]

BY ARTHUR SCHUSTER, PH. D., F. R. S., LANGWORTHY PROFESSOR OF PHYSICS AND DIRECTOR OF THE PHYSICAL LABORATORY, THE OWENS COLLEGE, MANCHESTER.

PROFESSOR ROENTGEN, of Würzburg, announces the discovery of remarkable photographic effects, which he ascribes to a new kind of radiation. As the statements which have appeared in most of the daily papers are inaccurate in many respects a short description of what Professor Roentgen claims to have accomplished may interest the readers of the British Medical Journal. The photographs which the Professor has kindly sent me fully bear out his statements, and there can be no doubt that the most important discovery has been made.

It has long been known that the highly electrical particles which are projected from the negative pole of a vacuum tube produce a strong luminosity (phosphorescence) when they strike against the glass walls of the tube. Professor Roentgen's discovery is that, in addition to this phosphorescence, another radiation is produced, which is capable of penetrating through all bodies; though not to the same extent—thus, aluminum is more transparent to this radiation than Iceland spar. The radiation passes in straight lines easily through paper, cardboard, or wood, and produces photographic effects after having passed through two complete packs of cards.

Professor Roentgen shows a photograph, which has been taken in one room, the tube producing the radiation being in another room, the rays having passed through the door. One of the photographs in my possession shows a complete image of a compass needle, with the divisions into degrees of the circle over which the needle is placed. The compass needle, before being photographed, was placed inside a metal box. As flesh, skin and cartilage are more transparent than bone, the photograph of a hand gives a complete outline of the bones of the hand and fingers, the outlines of the flesh being only very faintly marked. It is not necessary to enter into the many possible medical applications which this photograph opens out.

One characteristic feature of this new radiation, which distinguishes it from all effects so far known of radiant light and heat, is that it cannot be refracted or reflected; that is to say, it will pass through a prism of aluminium having an angle of 60 degrees without being deviated from its original course. Hence lenses will not focus the rays, which will pass through a lens as they pass through an ordinary glass window. The photographs obtained are, therefore, of the nature of shadows, and their great sharpness is itself a testimony that the new radiation must be propagated in straight lines.

The radiation produces fluorescence as well as photographic effects.

Professor Roentgen does not give any information as to the length of exposure required, but any photographic plate or film seems to act. The photographs may be taken in ordinary daylight if the plate is kept in its dark slide, which will completely cut off all ordinary light rays and yet transmit the new radiation.

It is, of course, impossible to say what this new radiation will turn out. Professor Roentgen throws out the suggestion that it may consist of longitudinal vibrations in the ether. One's first impulse is to ascribe it to vibrations of extremely minute length. But, in any case, the fact that the velocity of its propagation is the same in vacuo, glass and aluminium will be a puzzle to mathematical physicists.

PHILADELPHIA EDISON CO.

The report of the directors of the above company for the year ending December 31, 1895, shows that during that period dividends were paid to the amount of $147,764, or 8 per cent., in quarterly payments on the stock capital of $1,847,000. The total profits of the year, deducting dividends, operating expenses and individual profits, amounted to $300,233.10, a net profit of 10 80-100 per cent. on the capital stock. The gross receipts of 1895 exceeded those of 1894 by $5,000; but the profits were reduced by extensive repairs undertaken last year, which placed the property in good order.

TREATING EAST BERLIN WELL.

The Berlin Iron Bridge Company has built an electric light system and will shortly light the whole town of East Berlin, Conn., by electricity free of charge. The company does this for the benefit and the protection of its big plant, as well as for the benefit of the town. The company has made application to the Southern New England Telephone Company for permission to run its wires on the poles of the telephone company, and it has been granted.

[1] "The British Medical Journal," Jan. 18, 1896.

WHO PROF. ROENTGEN IS.

Now that both Europe and America are stirred up over the recent photographic discoveries of Professor Roentgen, a few details as to that scientist will be of interest. He is of Dutch birth, and his full name is Wilhelm Conrad Roentgen. He studied in Zürich, where he issued a monograph on the way to establish the relations as to the warmth that exists in atmospheric air. When Professor Kundt left Zürich for Würzburg his favorite disciple, Roentgen, followed, and later again to Strasburg University, where Kundt and Roentgen held the same position as professor and assistant. In 1873 he taught at Strasburg; in 1875 he became professor of mathematics and physics in Würtemberg at the Agricultural Academy of Hohenheim. But 1876 saw him back in Strasburg at the university, and in 1879 he became professor and director of the University Institute for Physics at Giessen. He has been at Würzburg University since 1888. He has written various works, such as (1873) a method to fix the isothermal surfaces of crystals, and on the use of the ice calorimeter to determine the intensity of sunlight. Then he turned to electricity and studied the figures produced in dust by electrical discharges as Professor Kundt showed them, and the curious phenomena shown by electricity passing through various gases. The absorption of ordinary heat rays by steam and gases generally occupied him also. Many other studies in physics may be put to his account; a new aneroid barometer to tell the weight of the atmosphere is his invention. In acoustics he studied the sounds emitted when gases are intermittently lighted up; he also published an exposition of the theory and working of the telephone. His essays may be found in Poggendorff and Wiedemann's "Annalen," the "Zeitschrift für Kristallographie," the reports of the Vienna Academy of Sciences, of the Gesellschaft der Wissenschaften of Göttingen, as well as in those of the Gesellschaft für Natur and Heilkunde of Upper Hesse, and of the Physico-Medical Society of Würzburg.

Prof. W. C. Roentgen.

THE NEW PHOTHOGRAPHIC DISCOVERY.

BY PROF. SILVANUS P. THOMPSON.

A very singular scientific discovery has just been made by Prof. Roentgen, of Wurzburg. It depends on the transparency of materials to those kinds of radiation which are invisible to our eyes. For long it has been known, and it was a favorite point in the lectures of the late Prof. Tyndall, that the invisible waves of heat which are stopped by metals can penetrate through rock salt; and that the equally invisible actinic (or photographic) waves can penetrate through quartz, but are largely stopped by glass. Then Abney discovered means of photographing the heat waves, and succeeded in photographing, by its own invisible radiations in a dark room, a kettle full of boiling water. Later it was found that an opaque screen of the hard, black india rubber, known as ebonite is transparent to heat waves. Some seven years ago by the researches of Hertz and of Lodge, it became known that electric wages, though arrested by metallic screens, can pass readily through walls of stone, brick, or wood, or through the human body. Meantime, discovery had advanced in another direction. In Crookes' classical researches on electric discharges in high vacua, he discovered that in the extremely attenuated gaseous residues in the tubes which he employed, the discharges from the negative pole or kathode can cast shadows on the walls of the enclosing tube. These kathodic rays have been investigated by many experimenters, including Goldstein, Wiedemann, and Lanard. They were found to be curiously active in exciting phosphorescence, and to travel quite differently from ordinary rays of light. The lamented Prof. Hertz added to these discoveries the observation that these kathode rays, though incapable of passing through glass, would pass through thin sheets of metal, which would be quite opaque to ordinary light.

And now Roentgen has put a crowning touch to these facts by the remarkable discovery which has excited the Viennese press. He has succeeded in finding a means of photographing an object of metal, though it may be all the while shut up in a wooden case. A special source of light (a Cookes' tube stimulated by electric discharges) is placed behind, and the camera, or rather the sensitive sheet, in front of the wooden box. These special radiations pass through the box more readily than if it were of glass, but cast a photographic shadow of whatever metal object may be in the interior. This is scarcely photography, in the ordinary sense of the word. It is rather the photographic registration of shadows. Glass lenses cannot be used to concentrate these rays; hence they cannot be employed to form images. If a sheet of sensitive paper is in turn shut up in a wooden box, and an object of metal is placed in front, its shadow, as cast by the radiations from the Crookes' tube, is imprinted on the paper. No "exposure" (as the photographer understands it) is necessary. Indeed, the sheet of paper may be shut up in one box, and the metal object in another, and yet the photograph may be taken. In the same way Prof. Roentgen is able to photograph a man's skeleton through the skin, flesh, and clothes, which for this purpose are photographically transparent, while the bones are opaque like the metals. Placing his own outspread hand outside the closed box containing the sensitized sheet, he obtained a print of the finger bones and of the rings on the fingers. Whatever, then, the new kind of light may be that produces these effects, it differs both from ordinary light and from the ordinary photographic rays, as well as from the visible kathodic rays discovered by Crookes; for the latter pass through metal, but are stopped by non-metallic substances. Prof. Boltzmann, whose authority in physical optics stands undisputed, regards the discovery as of the utmost importance from the scientific standpoint; for it reveals the existence of phenomena not explained in any of the accepted theories of light or of electricity.

For the multitude the discovery is no less wonderful; it adds one more to the marvels of science. To photograph in total darkness seems inexplicable; but that we should be able to photograph through walls of wood, or through solid and opaque bodies, is little short of a miracle. We shall now be able to realize Dickens' fancy when he made Scrooge perceive through Marley's body the two brass buttons on the back of his coat. We shall now be able to discover photopraphically the position of a bullet in a man's body. Even stone walls will not a prison make to the revelations of the camera.—London "Saturday Review."

THE ROENTGEN RAY PHOTOGRAPHY.

BY PROF. EDWIN H. HALL.

Scientific men who have kept track of electrical investigations carried on in Germany during recent years are surprised more by the magnitude than by the character of the achievements now credited to Roentgen of Würzburg in the application of kathode rays to photography. According to the accounts published in newspapers—for no description of his work has yet reached this country through scientific journals—this experimenter has succeeded in photographing bones through the flesh of living limbs, coins through a leather envelope, and iron through the wall of a wooden box. Hertz, whose name is known to all the world, showed four years ago that the so-called kathode rays, generated by electrical discharges through a rarefied gas, would pass through metal films impervious to ordinary light, and produce optical effects beyond. Lenard of Bonn, succeeded Hertz in this particular line of investigation, and has been until now the chief authority as to the penetrative power of these rays. In "Wiedemann's Annalen" for October, 1895, he has an article, the opening paragraph of which ber, 1895, he has an article, the opening paragraph of which will show the point which his experiments had reached at the time he wrote, and will explain why scientific men in this country were not prepared for the announcement of Roentgen's brilliant work. Lenard says in substance:

"Since it has been shown that certain metals are permeable by kathode rays, it is now in order to test the permeability of other materials. It appears that not metals alone, but all kinds of solids are permeable, though all in only very thin, delicate sheets. No solid body has been found to act toward kathode rays as glass acts toward light. Gaseous bodies are much more permeable than solids, and may be penetrated for centimeters."

He goes on to say that, having tried many solid and gaseous bodies, he is led to the conclusion that the permeability of a

body is pretty nearly proportional to its density (or specific gravity), without much regard to the state of aggregation or to the material of the body. For instance, he gives:

	Absorptive Power.	Density.	Absorptive Power / Density.
Air	3.42	.00123	2780
Collodion film........	3310	1.10	3010
Paper	2690	1.30	2070
Aluminum	7150	2.70	2650
Gold	55600	19.3	2880

Absorptive power is the opposite of permeability.

Apparently his experiments were limited, in the case of solid bodies, to sheets a few thousandths of an inch in thickness, although sheets somewhat thicker would have been permeable to a certain extent. He has shown, however, that the behavior of kathode rays varies somewhat with the manner or circumstances of their production, and it is quite possible that Roentgen has hit upon a much more powerful method of producing them than Lenard used. Hence, though it is well to wait for fuller details before accepting in full the remarkable stories of Roentgen's work, it would be rash to deny the possibility of their truth. Meanwhile a brief explanation of the terms used in connection with his work may be of interest.

Faraday, studying the galvanic cell some sixty years ago, felt the need of definite short names for the conductors by which the current of electricity, to use the common phrases, enters and leaves the cell. Faraday's education, like that of Edison, was not obtained at school, and he knew no Greek, but a learned friend furnished him with the term "anode" (upward way) for the conductor taking the current into the cell, and "kathode" (downward way) for that leading the current out from the cell. The two together were called electrodes.

A few years later Faraday studied the discharge of electricity from one piece of metal to another across a space containing rarefied air within a glass vessel. The pieces of metal leading the current in and out are called, as in the galvanic cell, the anode and the kathode respectively, and Faraday observed, as others had done, that the spark or brush or glow occurring within the tube during the passage of electricity was not of the same appearance at the two electrodes. He studied the phenomena with care, and suggested that the difference observed was due to a difference in the state of polarity or electric charge of the gas in the neighborhood of the two electrodes. This suggestion is by no means out of date, although it can hardly be said that this or any other theory of the matter has been generally accepted as satisfactory.

After Faraday came certain German experimenters, who made a special study of similar effects. Geissler made such advances in the apparatus used for showing electric discharge in rarefied air, substituting permanently sealed tubes with platinum electrodes for the comparatively clumsy and inconvenient apparatus of his predecessors, that the term "Geissler tube" soon became familiar in scientific literature. Geissler's improvements in the air pump enabled him to carry the rarefaction of the air to a high degree. The current is usually driven through the tubes by a Ruhmkorff induction coil, which furnishes a rapidly interrupted current. Ingenuity and mechanical skill were lavished upon the production of new forms and varieties of Geissler tubes, containing rarefied air, oxygen, hydrogen, etc., each showing its peculiar kinds of light, all of them beautiful and most of them inexplicable.

But in all, or nearly all, of them the kathode during action was surrounded by a narrow, colorless, or dark space outside, which was a glow of blue or violet light. The space around the anode and the greater part of the whole tube were also generally luminous, but in a different and far less clearly defined manner. It was evident, too, that more heat was generated at or near the kathode than elsewhere in the tube. The kathode, therefore, became the center of interest.

It was a common thing to use in the construction of Geissler tubes a kind of glass, called uranium glass, which has the peculiarity of giving out a greenish light when exposed to rays of light containing no green whatever. This kind of effect, which is shown in some form by various other substances, fluorspar, for instance, is called fluorescence. It was observed that the influence, whatever it might be, that especially produced fluorescence in Geissler tubes came from the kathode. It was observed, too, that this influence in very highly rarefied tubes appeared to come along straight lines from the kathode, and so the term "kathode rays" came into use, being suggested, of course, by the term light rays, although it was by no means certain that the kathode rays were rays of light.

Indeed, William Crookes, a distinguished English chemist, the inventor of the beautiful and interesting scientific toy called the radiometer or light mill, advanced the opinion that the so-called kathode rays were particles of matter, in what he called the "ultra gaseous" state, projected in straight lines from the kathode upon neighboring parts of the apparatus. Crookes, who is a man of great experimental resources, devised new forms of apparatus of such extraordinary interest that the term Crookes tube has now in great measure replaced the term Geissler tube.

But though the light generated in a rarefied gas, or in a fluorescent substance within the tube, by means of the kathode rays could readily be seen through the wall of the tube, it was observed that uranium glass placed near the kathode but outside the tube was not affected. That is, the kathode rays themselves, whatever they might be, could not pass through the thin glass wall of the vacuum tube. This was the condition of affairs when Hertz showed the kathode rays to have the power of passing through thin sheets of metal placed inside the vacuum tube. The next step, taken by Lenard, was to replace a very small part of the glass wall of the tube by a very thin piece of aluminum. This little spot of aluminum set in a glass wall he called a window, and through this window, which ordinary light could not traverse, the kathode rays which could not penetrate the glass went out into the open air, which they penetrated to a distance of about three inches, spreading out in all directions from the window as a center. They passed through the window in preference to the glass merely because the metal was thinner than the glass. Their presence in the air was shown by the faint glow of the air itself, by photographic effects, and by fluorescent effects like those already described, but neither the skin nor the eye exposed directly to the rays after they had passed the window gave any sensation.

If the kathode rays are light rays, they are apparently of the sort called ultra-violet, rays, which in passing through a prism are refracted more than the violet rays of ordinary sunlight. It is well known that such rays exist, and that they are effective in photography, though our eyes are incapable of getting any sensation directly from them. It need not surprise us to find that there are ultra-violet rays which do not readily penetrate glass, as there are other well-known rays which do not penetrate glass. The surprising characteristic of kathode rays, as Lenard has found them, is the uniform difficulty they have in passing through bodies of different materials. Apparently Roentgen finds much less uniformity in this particular.

Lenard seems to consider kathode rays as of the same nature with common light rays, but of much shorter wave length. He compares the obstruction they meet in passing through air with the obstruction ordinary light has in passing through a space partially filled with particles of a sensible size, dust particles, for instance. A serious objection to this view is the fact, recorded by Lenard himself, is that kathode rays are apparently deflected by a magnet, somewhat as a current of electricity is deflected, whereas common light, though yielding in some ways to magnetic influence, is not so affected. —New York Sun.

PHOTOGRAPHY OF THE INVISIBLE WITHOUT THE AID OF A BROOKES TUBE.

BY

William James Morton, M.D.

UPON reading about the results obtained by Professor Roentgen with the cathodic rays of Crookes' tubes, it occurred to me that possibly the same or similar results might be secured by the ordinary and familiar electric radiations from influence machines and induction coils. May not such radiations, whether invisible of partially visible, produce the effect thus far claimed to be peculiar to the "X rays" at the cathode of the Crookes' tube? Some recent experiments which I have made would seem to prove that the above view is correct.

I submit a few experiments for what they are worth. They would seem to demonstrate that objects, enclosed and invisible, when interposed in the pathway of ordinary electric radiations, may be photographed upon relatively distant sensitive plates by reason of variations in the strength or quality of the radiations produced by the interposed objects.

The well-known images produced by a coin or other metal object laid directly upon a sensitive film and electrified are not here referred to, since in my experiments the interposed metal was separated from the film by several thicknesses of heavy cardboard or of wood one-quarter of an inch in thickness, in this respect exactly repeating the experiment of photographing coins within a purse or a box. I have obtained two classes of results:

(a) The interposed and invisible metallic object produces a black image of itself upon the sensitive plate.

(b) The same object produces a white image of itself, showing that it has entirely intercepted the rays.

This statement refers to the effect produced upon the sensitive plate. A print, of course, would exhibit in the former class white and in the latter class black images. The latter only corresponds to the photographic "picture" which I understand to be produced by the cathodic rays of a Crookes' tube and which may be termed a cathodograph. (Query: Is not the print exhibiting white images an anodograph?)

Experiment 1., Fig. 1.—A sensitive film was placed inside of an ordinary film holder or box commonly used to pro-

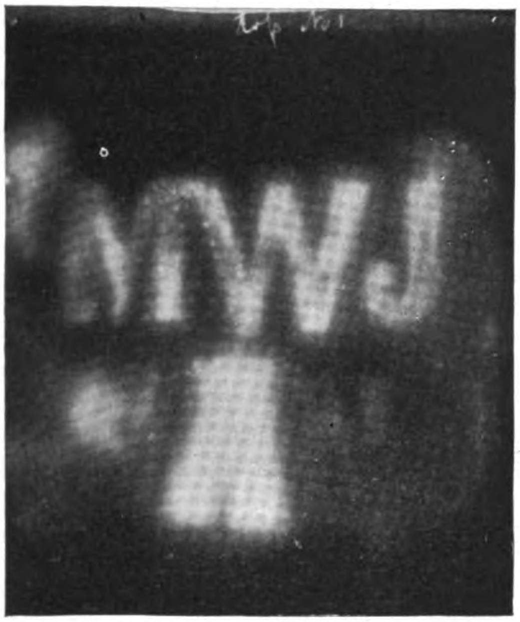

FIG. 2.

tect it from light before exposure in the camera. This box consists of wood and blackened cardboard slides. Upon the outside of the box was laid the letters C O P, cut out of a very thin sheet of pure copper. Upon the letters was laid another sheet of cardboard of the same size as the box, namely, 4x5 inches, the whole securely clamped by strong rubber

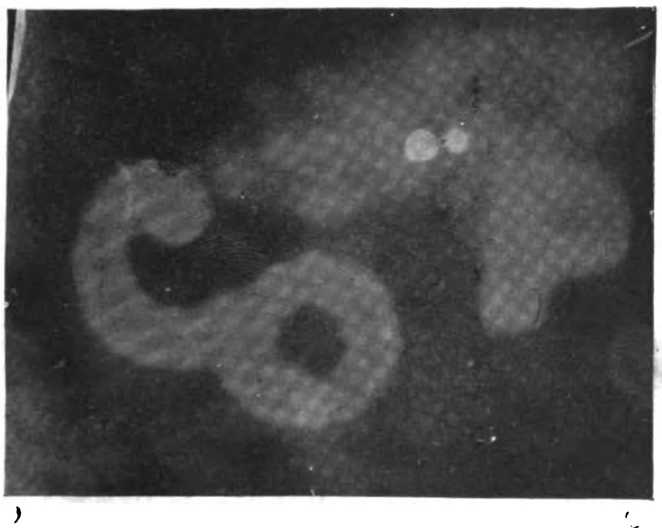

FIG. 1.

bands. An influence machine was then set in action with the following adjustment. To avoid sparks no Leyden jars were used. The negative discharging rod was the ordinary brass ball, one inch in diameter, the positive a sharp point, the two separated about six inches and the prepared box placed in the intervening field in such a manner that it laid against the negative ball. The characteristic "fox tail" or brush discharge from the positive point extended nearly to the box; no spark appeared at the negative pole or elsewhere. After five minutes' exposure in this field the film was developed, and presented the appearance represented in Fig. 1. (The letter O had slipped out of line.)

This experiment has since been repeated much more satisfactorily and in every instance produces a black image of letters or of coins upon the film.

Experiment II., Fig. 2.—Film holder arranged as in proceeding experiment, except that other copper letters cut from the same sheet were substituted and covered with additional layers of cardboard. The box and wood thus prepared was held for five minutes between the poles of the secondary circuit of a "high tension" induction coil, whose primary current was an oscillating Leyden jar and spark gap current. The distance apart of the two sharp pointed terminals was about three inches, and only a slight visible brush discharge appeared at these terminals. Upon developing the film the letters appeared outlined as represented in Fig. 2—namely, M, W, J and A.

Experiment III., Fig. 3: A "cathodograph."—The influence machine was arranged substantially as described in Experiment I. The copper letters were loosely laid upon the outside of the box containing the sensitive film and retained in place by other pieces of cardboard laid upon them and clamped by strong rubber bands, thus fulfilling every condition of an invisible object. Exposure to the influence of the radiation was five minutes. Upon developing the film, the letters, instead of appearing black, were now white, while the remaining portions of the film were black. The print exhibits the black letters W. J. M., Jan. 30, '96.

This result would seem to indicate that the copper letters had intercepted the radiations. The outlines, it is true, are not as clear cut as could be desired, but this no doubt is accounted for by the varying texture of the enclosing envelope, which was far from homogeneous. I have also obtained other "cathodographs." In conclusion, experiments I have thus far made, including many not detailed here, lead me to believe that cathodic rays capable of producing some of the effects described by Professor Roentgen are not confined in their production alone to high vacuum tubes, but may be detected, under proper management, in connection with ordinary electrical exciters.

PERSONAL.

MR. E. W. LITTLE has resigned from the managership of the Interior Conduit and Insulation Co., and informs us that he will not hereafter be connected in any way with that concern. While Mr. Little is reticent as to his plans for the

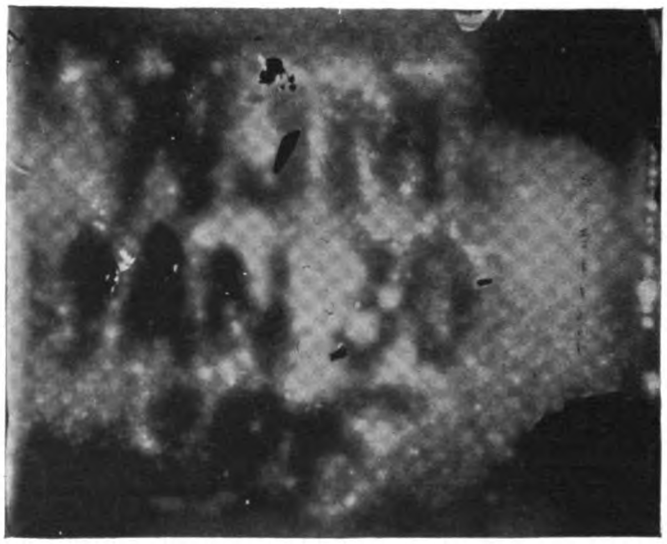

FIG. 3.

future, it may be safely assumed that he will engage in some other electrical enterprise, where his long experience in the general field will prove of great value. Mr. Little has among other things, seen the interior conduit business evolve from nothing into a great and growing industry, and has taken a very active share in the work.

MR. E. H. FOERST, of San Francisco, who has been in New York on business for the past five or six weeks, has returned to the coast, after securing for his company many valuable agencies. Mr. Foerst has been a familiar figure in the electrical center of Cortlandt Street, and he will be much missed, as he has made many friends for himself while East.

CATHODOGRAPHS AND PHOSPHOTOGRAPH.

THE remarkable, not to say sensational, effects obtained by Prof. Roentgen in securing cathodographic impressions on a photographic plate of objects screened from light rays, has set experimenters and investigators to work the world over, and results are beginning to be recorded from many quarters. American physicists, we are glad to know, have not been found lagging in their efforts to take up and carry further the work begun so auspiciously, and we are glad to be able to place before our readers in this issue a reproducion of fine cathodographs secured by Prof. A. W. Wright, of the Sloane Physical Laboratory of Yale University. A contemplation of this print, which must of necessity lack some of the sharpness of detail possessed by the original plate, cannot fail to impress the reader with the marvellous result achieved in this new field. One can as yet barely speculate on the paths opened up not only for the direct application of the discovery, but for the clue it may give to a further elucidation of the properties of the ether, and correlatively with that, of the multitude of phenomena directly involving the action of the ether. Like most discoveries of this nature, it may, at least in part, be traced back to the ideas and facts set forth by previous experimenters. In the present instance the work of Hertz and of his disciple and successor, Lenard, without doubt contributed largely to guide Prof. Roentgen in his great achievement, but no one will on that account begrudge the credit due him as the first one to obtain these novel results. An interesting contribution to the subject under discussion is that by Prof. Elihu Thomson, which we print elsewhere in this issue. With the true faculty of the inventor always active, Prof. Thomson suggests a novel method of constructing a cathode ray generator. While thus far results had only been attained with Crookes' tubes it seemed not improbable that effects of a similar nature might be attained without the employment of highly vacuous enclosures; indeed this opinion is shared by not a few and has been experimentally tried by Dr. W. J. Morton, of this city. Some of the results thus far attained with this method by Dr. Morton have been placed in our hands by that eminent electro-therapeutist, and are illustrated in this issue. They present certain peculiarities which will no doubt give rise to further discussion.

A substantiation of the contention that the Crookes tube is not necessary to obtain the desired effects is also found in the strange announcement which reaches us as we go to press, that M. Lebon, in France, has succeeded in affecting screened sensitive photographic plates by the rays emanating from an ordinary oil lamp. If this experiment should be confirmed, and it would require very little time and trouble to do so, it seems not unreasonable to believe that like results can be obtained with ordinary sunlight. We may also note that Prof. Dolbear claims to have obtained photographic prints of screened objects by the aid of radiations from a static electrical machine. In the mean time the de-

mand for Crookes' tubes has, we understand, created a "corner" in that commodity.

While devoting space to the presentation of the subject we have deemed it well to bring out in contrast to it the most recent development in actual photography by the aid of the vacuum tube light. Mr. D. McFarlan Moore, of the progress of whose work we have made note from time to time, has made rapd strides in the improvement of his aparatus, and no better proof of the advanced ground occupied by this young inventor could be submitted than the reproduction of the photograph which forms the subject of the supplement to this week's issue of "The Electrical Engineer." What this picture means can perhaps only be fully realized by those who have themselves worked in the field of vacuum tube lighting or have witnessed experiments in it. The volume and intensity of the light indicated by this picture are far beyond anything of this nature which has before come under our notice, and the simplicity of the apparatus by which it is produced seems to us one of the strongest arguments for its claims to a practical solution of the long sought for "light without heat."

ELECTRICITY IN WARFARE.

NOT a few of our American and English contemporaries, electrical or otherwise, have recently devoted considerable space to the plans suggested by Mr. Edison for the defense of this country should it be unfortunate enough to have to go to war, all of a sudden, over some question of fish lines, boundary lines or poetical lines—for, in reality, the appointment of Mr. Austin as poet laureate of the English speaking peoples seems to us a more serious casus belli than any other now before the public. We have read with deep interest all that Mr. Edison has had to say on the vital subject of coast defense, and must confess we can find in it nothing more than the shrewd, ingenious and noteworthy suggestions of a true-born Yankee inventor. Mr. Edison deplores the bare mention of wanton bloodshed, but intimates that if we had to protect ourselves in a hurry, there are various electrical novelties which might count.

To a certain extent, these amiable discussions are like those which flighty young ladies indulge in when they ask what each other would do if there were actually a burglar under the bed; but they have a practical side. They serve first of all to call attention to the wretched state of unpreparedness in which the nation allows its its necessary defense to linger. After all, no man is imprudent or bellicose because he takes out a fire insurance policy or maintains a fire brigade; and in that light military and naval defense must ever be regarded. But lacking a policy of readiness, the patriotic inventor is not to be scorned for suggesting buckets of sand or hand grenades in an emergency. Mr. Edison has hinted at many possibilities of electricity, and at some things which are more than possibilities. Perhaps only a war could determine whether he is wholly right or utterly wrong. It is one of the very few compensations of war that it helps perfect ideas and inventions which in the long run are of great value in the arts of peace.

The most sober and effective critic of Mr. Edison is Lieut. B. A. Fiske, himself no mean electrician or inventor, but his quoted remarks sum up into the highly practical point that no matter how good some of these Edisonian novelties might be, men are needed who have been drilled and trained to handle them. Probably Mr. Edison would be the first to accept this sensible dictum, but no inventor stops producing because a corps of experts has not been trained in advance to manipulate his latest devices before they come out. By all means let us have some more skilled electricians in the army and navy, more expert balloonists, more torpedo and submarine navigators; and do not let us sneer at or be afraid of trying the new ideas that the innovating Armstrongs, Nordenfeldts, Maxims, Ericssons and Edisons venture to offer, not as substitutes for a respectable army or navy, but as fitting auxiliary tools and weapons for a modern arm of defense. Congress might do much worse than save a little money from other appropriations for the trial of such devices.

FUSE VS. MAGNETIC CUT-OUT.

THE permanence of an art, let alone its progress, must depend largely on the reliability of the apparatus employed in it, and in this term must be included the factor of safety. From the very first, the fire hazard connected with current distribution has been forced upon the electrical engineer, and indeed its consideration still constitutes a live question before electrical bodies towards which the constant pressure brought upon them by the fire underwriters has contributed not a little. The fusible cut-out has long been the subject of special attacks, but one of the strongest indictments thus far formulated against its use is the report of Mr. Wm. McDevitt, of the Philadelphia Board of Fire Underwriters. In view of the probable effects of the submission of this report we have deemed it well to print it in full in order to place before our readers all the evidence adduced by its author in his sweeping condemnation. That Mr. McDevitt does not stand alone in the position taken by him no one who is familiar with the drift of opinion in electrical circles will deny, and the increasing number of specifications calling for magnetic circuit breakers for circuits carrying above 15 or 20 amperes strongly supports Mr. McDevitt in his contention. The fuse has done good service, but if its day of usefulness is gone for heavy currents, then it must give place to its old competitor, even though its low cost is not the least of the arguments in its favor.

This week "The Electrical Engineer" appears in a new dress of type, which it believes to be in many respects more handsome than its recent garb of type. It trusts that the change will be accepted as another proof of the intention of the paper to give its readers the best.

TELEPHONY AND TELEGRAPHY.

THE HUMBLE BEGINNING OF THE WESTERN UNION

In some recent reminiscences, Mr. W. B. Levet, of Rochester, N. Y., says:

The writer first entered the service of the Western Union Telegraph Company in 1857 as clerk in the office of Isaac R. Elwood, the first secretary and treasurer of the company, a man whose integrity was never questioned, and whose conservative policy in connection with the operation of the company in those early days inspired confidence in it among the business men, which had much to do with its ultimate success. I was introduced to Mr. Elwood by Judge Robert Wilson (known as "Bob" Wilson, of Mexican fame) and remained with the company until its removal to New York in 1866. At that time the secretary and treasurer's office occupied only the first room over what is now the Bank of Monroe. All the financial and executive business of the company at that time was transacted in that one room by Mr. Elwood, F. G. Ritso, bookkeeper, and myself as clerk. Subsequently the president, Hiram Sibley, occupied one of the back rooms as an office, and later the two back rooms were thrown into one and used for a directors' room and a large fire proof safe was procured. I well remember making out the list of stockholders and the amount held by each for the first dividend, which, if my memory serves me aright, was 20 per cent. cash and 16 per cent. stock, the total capital thus increased being $116,000. These dividends were soon followed by other and larger ones of both kinds.

Besides the gentlemen you mention who were associated with Mr. Sibley in the undertaking were Ezra Cornell, of Ithaca, father of the ex-Governor, who was the prime manipulator of the Erie and Michigan Telegraph Company, which was really the basis of the Western Union. In after years a share of the original stock of that company was worth a small fortune. Henry S. Potter and Joseph Medbery, of Rochester, Joseph H. Wade, of Cleveland, and Anson Stager, of Ashtabula, and many of the prominent citizens of Rochester were afterwards auded to the directors and the business rapidly increased.

Before the Russian Extension Company, the overland line to the Pacific coast, was built, special stock being subscribed, for that route was accomplished under very serious difficulties. In many instances he had to rely on the "Pony Express," which then carried the mail to the Pacific coast, as his escort and only guide. That line, built under almost insurmountable obstacles and which was the forerunner of the Pacific Railroad, proved to be a bonanza both for the contractor and the stockholder. A good deal of the present wealth of Rochester may be traced to the investments therein made, while Cornell University at Ithaca, Sibley Hall on our own campus, Wade Park at Cleveland and Creighton College of Omaha, each bearing the name of its generous donor, are to be traced to the large fortunes made from this venture. All honor to these men for their generosity to their fellow citizens. All of them are, I believe, dead, but by these acts they still speak. I remember well one time when the receipts of the California office were sent to the treasurer's office here in gold coin, and the clerks who counted it were requested by Don Alonzo Watson, in a quaint way he sometimes had, to save the water when we washed our hands, as it would be a capital thing to "water the stock" with.

Excitement ran high in those days, and Rochester has never seen such times since. The efforts and strategy employed to secure stock when it was increasing in value every hour, and fabulous values were attribute to it, will never be forgotten by those who saw it from within. When it was hinted or surmised that a dividend was to be declared, investors and speculators were wild to possess it, and the transfer books were kept hot for days before they were closed. Many of the most valuable parcels of real estate in this city were purchased with this stock at greatly inflated values.

When the Russian extension line was projected, which was not until after the first Atlantic cable failed, Samuel Wilder, one of the directors, was dispatched to New York as purchasing agent for the necessary supplies for that project, and after long and laborious effort on his part, when the good ship Milton Badger (the first of three vessels sent) was loaded and sailed from that port to Behring Strait it was supposed that the initial step had been taken for the production of another rich harvest. but, alas; after the expenditure of many hundred thousands of dollars and before the Badger reached the straits, Cyrus Field, by his indomitable perseverance, had laid the second Atlantic cable. which proved successful, and the Russian extension was an immense failure, and probably many of the poles intended for other purposes have served distinguished families among the aborigines as totems, while the axes, shovels, wagons, insulators and other implements have been used for other purposes by the natives, and the beads and other trinkets have undoubtedly adorned many a Russian beauty who then inhabited those bleak regions.

For many years Rochester was in various ways benefited during the company's life here. Among other things the "Evening Express" Company, I remember, had a contract to supply all their printing, so that all the blanks, envelopes and other stationery were supplied by the company to all the offices throughout the country.

TELEGRAMS A "PRIVILEGED COMMUNICATION."

The recent decision of Chancellor Sneed, of Tennessee, that telegraphic dispatches are privileged communications, and that their secrecy may not be violated by the courts except in the most extraordinary emergencies, was based not alone upon the law of the State that telegraphic messages are confidential, but also upon abstract reasoning, from the standpoint of common law. Not the least of the obligations indispensable to the efficient operation of the telegraph as a commercial agent, the Chancellor said, is the confidential relation between the agencies of the telegraph and its customers. There is no instrumentality in public or private business which the people have to draw more closely into their confidence. To rule, as courts have done, the Chancellor continues, that agents of a telegraph company might at any time be called into court to betray matters which came to their knowledge in the transaction of their business, is a "violation not only of public policy, but of the rules of right and the implied contract of the parties. Aside from the positive legal restriction, it would seem that the usefulness of the telegraph as a commercial agent would be irretrievably impaired by the practice referred to, as the most important correspondence between the commercial man and his agent, a correspondence on which fortunes may depend, is often carried on through the telegraph, in which the most delicate questions are sometimes in good faith asked and answered, and in which other men's affairs are brought into question in a manner that might lead to trouble or litigation when no harm was intended. It would seem just as reasonable to establish a judicial espionage over the mails and to compel the postmaster to surrender or break open letters and reveal the secrets of all or any private correspondence that may come into his possession."

FOR A PACIFIC CABLE.

At a conference of the Postmaster General of the Australian Colonies, in Sydney, N. S. W., Duncan Giles and Sir Saul Samuel, Agents General in London of Victoria and New South Wales, respectively, were appointed Australian delegates on the Pacific Cable Commission. The conference adopted a resolution declaring that Great Britain, Australia and Canada should each pay one-third of the cost of the cable; that the landing places should only be on British territory, and that the route from Fiji should be to Norfolk Island, from which place the line should go to North Island, New Zealand, and to Moreton Bay, on the east cost of Australia.

LETTERS TO THE EDITOR.

HERE'S ANOTHER PHOTOGHAPHIC SUGGESTION.

Having been greatly impressed by a passage in Tom Hood, which I came across not long ago, I judge your readers may be likewise interested, and I accordingly inclose herewith. The application is obvious. G. H. STOCKBRIDGE.

New York City.

Here is the passage: "But in this century of invention, when a self-acting drawing paper has been discovered for copying visible objects, who knows but that a future Niepce, or Daguerre, or Herschel, or Fox Talbot, may find out some sort of Boswellish writing paper to repeat it whatever it hears!"

AN EARNEST OF PROGRESS.

Your issue of January 8th is an earnest of progress and stability. It not only says, "We are here," but "Come along."

P. B. DELANY.

IT MAKES ONE'S MOUTH WATER

It gives me great pleasure to testify to the pleasure I have already had in reading the very complete and admirable article, in your issue of January 8th, upon the New York electric lighting stations. It makes one's mouth water, so to speak, in the way of wishing to also be an electric light maker, with a good enough plant to be so well written up.

OBERLIN SMITH.

MISCELLANEOUS.

THE GROSS UNTRUSTWORTHINESS OF FUSE METALS AND APPLIANCES AS A MEANS OF PROTECTION FOR ELECTRIC CIRCUITS.—THE REMEDY.[1]

BY WM. MCDEVITT, INSPECTOR, PHILADELPHIA BOARD OF FIRE UNDERWRITERS.

IN all the strides for improvement in electrical devices there is none which has received as little attention, when considering its importance, as that of fuses and their appliances.

In the first attempts in the application of fuses and fuse blocks, great trouble was experienced, owing to use of wood for blocks, too short space between terminals, arcing, heating from insufficient carrying of screws and terminals. Troubles of a serious character manifested themselves, due to the above defeats, resulting in burning or charring of wood, loosening of contacts, and, in many instances, the total destruction of the entire fuse block. Porcelain was finally adopted as the means for overcoming the objections inherent in the older wood fuse block.

The old troubles still continued, and changes have been made from time to time in the terminals, screws, distances between terminals, etc.

For several years back instances have occurred to my knowledge where the line, although properly fused, has been seen to give off smoke, followed by the virtual roasting and destruction of the insulation. Investigation proved that this was due solely to the sluggish action of the fuse when the circuit was either overloaded or short-circuited.

Alloys of different compositions have been used. Experience has proven that some chemical change takes place, either from oxidation or action of the current, resulting in variation in fusing current required. In some instances, to my knowledge, the fuse blowing far below its rated capacity, thus made a temptation for users to fuse higher than good judgment would dictate

Owing to the repeated cases in my experience, such as burned-out fuse blocks, charred insulation on wires, burned gas pipes, etc., the grave fire risks attendant upon the use of fuses and fuse blocks, has continually obtruded itself upon me, and has led me to examine into the subject of fuses and their appliances very carefully.

The gross unreliability of fuse metals, and the lack of dependence to be placed upon the best designed fuse blocks used in practice, has forced me to the opinion, that in all cases of over 10 amperes capacity, fuses and their appliances, while generally operating as desired, under certain conditions, however, are a serious fire risk, not only in themselves, but in their failure also as a protector. As some criticisms have been made concerning my opinions for some time past, the following tests and quotations from authorities upon fuse metals are herewith given to emphasize the claims of the writer as to the gross unreliability of fuse metals, and the fire risks attendant upon their use in all cases over 10 amperes' capacity. Further, the tests show the lack of dependence to be placed upon the fuse blocks used in practice.

The following tests were made in Philadelphia, January 14, 1896, across the terminals of a 100-light, 110-volt dynamo. A Weston ammeter, a water rheostat, a main switch, and the fuse blocks were all in series. A short circuiting switch around the fuse was used in most instances, permitting the current adjustment with water. rheostat before throwing current upon the fuse to be tested. In many instances commercial fuse blocks and standard fuse metals were employed.

No. 1.—Standard 30 amperes. D. P. Cut-out, strip fuse, main line, five-light standard link fuse, 3½ amperes. The dynamo magnetic circuit breaker set at 25¾ amperes. Current of 26½ amperes passed through fuse and breaker five consecutive times, and protecting fuse; fifth time blew fuse, but did not open breaker.

No. 2—.Five light fuse, 3½ amperes. Blew at 26 amperes.

No. 3.—Five light fuse or 3½ amperes. Ten to twelve tests on fuse without blowing with current of 27 amperes every time. After this 15 amperes was run through same fuse for 1½ minutes, heated fuse slightly but did not blow. Then same fuse carried 30 amperes, for 9 seconds, became red hot before blowing.

No. 4.—Ten-light standard link fuse, 7 amperes. Held 15 amperes for 30 seconds, became red hot, and blew.

No. 5.—Ten-light standard link fuse, 7 amperes. Carried 14½ amperes 3 minutes and 10 seconds. Maintained red heat 2 minutes of that time before blowing.

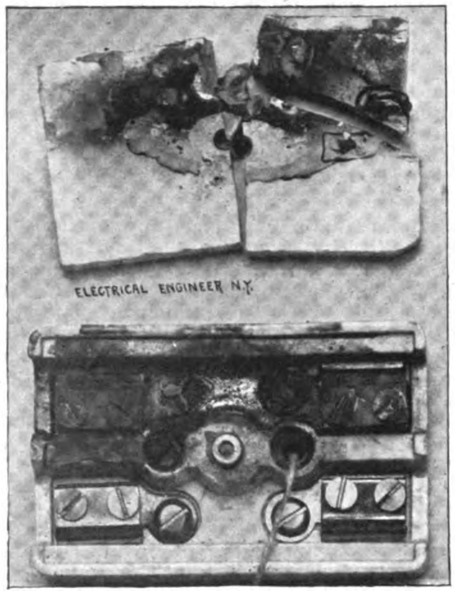

EXHIBIT WITH TEST NO. 19.

No. 6.—Fifteen light standard link fuse, 10½ amperes. Circuit breaker, 46½ amperes. Opened six times without perceptible change in fuse. Then this fuse carried 30 amperes 28 seconds.

No. 7.—Fifteen-light standard links, 10½ amperes. Circuit breaker set at 46½ amperes. The fuse carried 40 amperes 5 seconds, became red hot before blowing.

No. 8.—Twenty-light standard links, 14 amperes. Carried 40 amperes 18 seconds, white flame, arced for some time before breaking circuit.

No. 9.—Twenty-light standard link, 14 amperes. Fuse block covered with mica. Carried 40 amperes 18 seconds; heated, burned mica badly before blowing.

No. 10.—Twenty-light standard links. Block covered with mica. Carried 40 amperes; mica burned about half way through; time 22 seconds

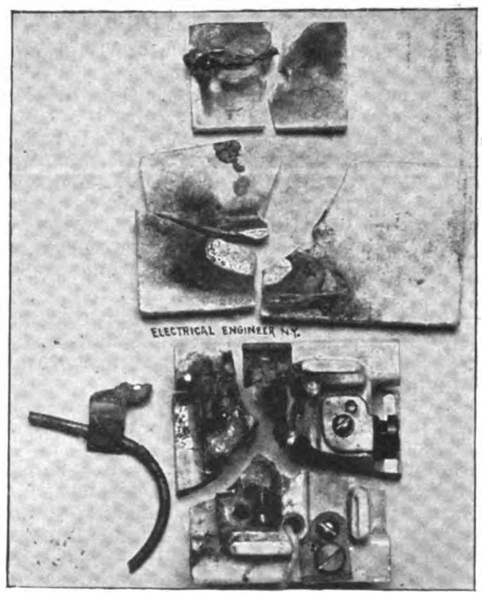

EXHIBIT WITH TEST NO. 23.

No. 11.—Twenty-light standard links. Same as before. Current 40 amperes; time 32 seconds. Burned mica still further.

No. 12.—Thirty-light standard link fuse; 21 amperes. Covered with fresh mica. Main circuit breaker, after 50 seconds, carried current from 40-43 amperes Fuse showed dull red before blowing.

[1] Report submitted to the Philadelphia Board of Fire Underwriters.

No. 13.—Same fuse, 21 amperes, as before. Mica covering new anl clean, carried current of 45 amperes 55 seconds; damaged base.

The standard block replaced with 25 amperes. Branch block marked (A)

No. 14.—Fuse, 15 amperes, standard fuse. Carried 40 amperes 1 minute; then arced for at least 10 seconds The block was lying on back

No. 15.—Fuse, 15 amperes, standard fuse. Block vertical, lying lengthwise. Carried 40 amperes 28 seconds; then fused and arced 32 seconds. Cracked lid, composition ran out back. Block cracked from heat. Vicious, continued arcing. Destroyed the block A.

No. 16.—Standard main line 25, lying lengthwise. Fuse (15 amperes), edge of block forming a shelf for fuse and covered. Current carried 40 amperes 2 minutes; 45 amperes 1 minute. Showed only slight variation in color. Current withdrawn.

No. 17.—Same fuse, 15 ampere, standard; 1 minute carried 40 amperes; next minute 45 amperes; slight change in color. In this test the block was turned on short end. Edge of block forming a shelf for fuse, as before, and horizontal. Current withdrawn.

No. 18.—Block uncovered. Same fuse, 15 amperes, not touching block. Carried 40 amperes 35 seconds and blew. Block standing on short end, fuse vertical.

No. 19.—Fifteen ampere fuse, standard, same block. Covered, lying on back in proper position, as on ceiling. Fuse touched lid. Carried 45 amperes for 20 seconds; then arced with 27 amperes 33 seconds, producing exhibit No. 2, Burned seriously, vicious, continued arcing; destroyed the block. (See Exhibit.)

No. 20.—Standard main line D. P.; thirty-light link, standard fuse; 21 amperes; block face (mica) down. Carried 40 amperes 1 minute; 45 amperes for the next 50 seconds. Blew against mica.

No. 21.—Same block, fuse, and position as No. 20; 45 amperes 22 seconds. Blew with small arc against mica.

No. 22.—Same block and position, against mica; 15 amperes standard. Carried 45 amperes. Blew in 17 seconds.

No. 23.—Ten amperes, branch block marked exhibit No. 3; 10 amperes standard fuse. Stood on its side, fuse horizontal, cover on, carried 35 amperes, and blew in 5 seconds. Arced for 35 seconds. Current in arc dropped from 28 to 18 amperes, arching vicious. Block destroyed. (See Exhibit.)

No. 24.—No. 2,165 standard plug. Block face down; 3 wire main line, 30 amperes, ten-light plug. Carried 20 amperes 5 seconds; actual carring capacity of fuse 3½ amperes. Practically 500 per cent. overload.

No. 25.—Same block, 15-light standard plug; 5 amperes, standing on narrow end; face exposed; 1 minute 20 amperes; next 30 seconds 25 amperes; next 30 seconds 30 amperes. Blew.

No. 26.—Same block; face exposed; block lying on back; 30-light fuse; 10½ amperes. Carried 40 amperes 1 minute; 45 amperes, 1½ minutes, and blew; 400 per cent. overload.

No. 27.—Same as test No. 26.

The following tests were conducted in the power station of the University of Pennsylvania, Jan. 17, 1896, by courtesy of Prof. Spangler. Connections and instruments similar to tests made Jan. 14 were used. Connections were made across leads of a 110-volt, 500-light dynamo. The tests, as shown herewith are exceedingly interesting, as they were made upon larger fuse metals and fuse blocks than in test of Jan. 14.

No. 28.—Standard branch block; 30 amperes; 30 amperes standard fuse; 60 amperes, 3 minutes; 65 amperes, 1 minute; 70 amperes, 1 minute; no discoloration noticed; 75 amperes, 1 minute, standing upright.

No. 29.—Same block, same fuse; 80 amperes, 1 minute; 85 amperes, 1 minute; 90 amperes, 45 seconds; blew and arced 4 seconds; burned hole in mica.

No. 30.—Same block as No. 28; 30 amperes; standard fuse, touching mica. Carried 100 amperes 12 seconds.

No. 31.—Same block as No. 28; 30 amperes; standard fuse. touching mica; block face down. Current increased gradually to 75 amperes in 22 seconds.

No. 32.—Block upon edge, standing upright; same block as No. 28; 30 amperes; standard fuse. Carried 80 amperes 20 seconds.

No. 33.—Same block; 30 amperes; standard fuse link; 40 amperes, 1 minute; 45 amperes, 1 minute; 44 amperes, 2 minutes, 20 seconds. Kept reduced temperature until current was withdrawn.

No. 34.—Standard link fuse block; main line double pole; 50 amperes, fuse block resting on bottom; 50 amperes; standard fuse. Carried 70 amperes 45 seconds; 75 amperes, 1 minute; 80 amperes, 1 minute; 85 amperes, 2 minutes; 90 amperes, 1 minute 10 seconds; 95 amperes, 1 minute 20 seconds; 100 amperes, 1 minute 30 seconds; 105 amperes, 1 minute 10 seconds; 110 amperes, 1 minute 35 seconds; 115 amperes, 1 minute 10 seconds; 120 amperes, 1 minute; 125 amperes, 1 minute 60 seconds; 130 amperes, 1 minute 75, 74, 72 seconds. Arced 1

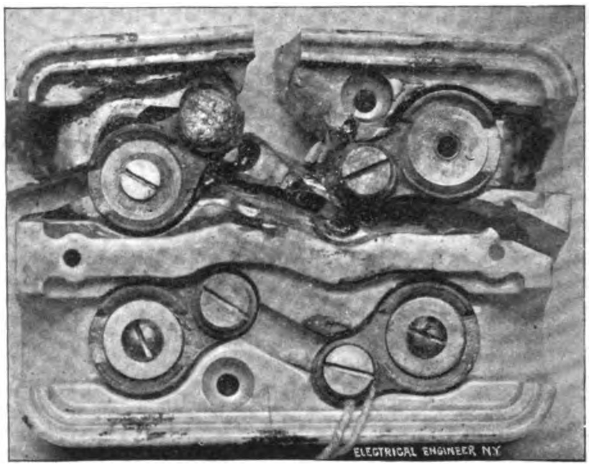

Exhibit With Test No. 34.

minute 7 seconds; 65, 70, 65 and 45 degrees, very bad continued arcing. No. 6 copper leads become hot, followed by insulation running, serious heating of wire (note size of wire). Destroyed block. (See exhibit.)

No. 35.—Standard 50-ampere D. P. Main line fuse block; 50 amperes standard fuse; fuse block upon its side. Carried 70 amperes 2 minutes; 75 amperes, 1 minute; 80 amperes, 1 minute; 85 amperes, 1 minute; 90 amperes, 1 minute; 95 amperes, 1 minute; 100 amperes, 1 minute; 105 amperes, 1 minute; 110 amperes, 1 minute; 115 amperes, 1 minute; 120 amperes, 1 minute; 125 amperes, 20 seconds; arced 3 seconds. Mass of molten metal laid in bottom, which arc could have passed over.

No. 36.—Same block; new side; 40 amperes; standard link fuse. Rated to blow at 50 amperes; 50 amperes, 1 minute; 55 amperes, 1 minute; 60 amperes, 1 minute; 65 amperes, 1 minute; 70 amperes, 1 minute; 75 amperes, 30 seconds. Slight arc.

No. 37.—Same block; 50 amperes, standard wire; lengthwise position; 75 amperes, 1 minute; 80 amperes, 1 minute; 85 amperes, 1 minute; 90 amperes, 1 minute; 95 amperes, 1 minute; 100 amperes, 1 minute; 105 amperes, 1 minute; 110 amperes, 1 minute; 125 amperes 13 seconds. Arced 13 seconds; destroyed block.

The following are quotations from various sources, and authorities, bearing upon fuse metals in general. Experimental and observed data have been accumulating very rapidly the last two years. The last year has been praticularly prolific in data.

A PROMINENT FUSE WIRE COMPANY'S CATALOGUE.

I.] The fusion necessarily depends upon all the elements that effect this heating. It takes time to heat even a wire, and people are sometimes greatly disappointed because a fuse does not open a circuit with the rapidity of a photographic drop-shutter the instant there is a sudden increase in load.

II.] It shows, however, that on account of the time required to heat the fuse to melting point, one cannot expect it to do the work of an automatic cut-out, which opens the circuit instantly at a set strength of current.

III.] If sudden increases in current cause other serious troubles, an automatic cut-out is wanted—not a fuse.

THE HEATING AND BEHAVIOR OF FUSE WIRES.

A paper read by Prof. W. M. Stine, H. E. Gaytes, and C. E. Freeman, before the American Institute of Electrical Engineers, Oct. 23, 1895.

IV.] We may now summarize some of the practical conclusions deduced. 1. Covered fuses are more sensitive than open ones. 2. Fuse wire should be rated for its carrying capacity for the ordinary lengths employed, 2a. When fusing a circuit the distance between the terminals should be considered. 3. On important circuits fuses should be frequently renewed. 4. The inertia of a fuse for high currents must be considered when protecting special devices. 5. Fuses should be operated under normal conditions to ensure certainty of results. 6. Fuses up to five amperes should be at least 1½ inches long, ½ inch to be added for each increment of five amperes' capacity. 7. Round fuse wire should not be employed in excess

of 30 amperes capacity. For higher currents flat ribbons exceeding four inches in length should be employed.

DISCUSSIONS FOLLOWING PROF. STINE'S PAPER ON "THE RATING AND BEHAVIOR OF FUSE WIRES."

V.] The Chairman (Prof. F. B. Crocker).—This paper, while dealing with a question that is by no means new, and should long ago have ceased to be a subject of discussion, is, nevertheless, one which is more constantly discussed and no more settled, than many of the problems which are far more difficult inherently. The physical conditions governing the fusion of a wire would appear to be very definite and easily determined. Certainly, no one would imagine that this sub-
VI.] ject would be one of the last to become definite from our point of view. But the fact remains, that to-day fuse wires are by no means relied upon; indeed, the very term "fuse wire" is almost synonymous with unreliability. It certainly would not seem that this is a necessary condition. I think it is owing to the fact that the length of the wire, the terminals to which it is attached, and the question whether it is enclosed or open, and many other important conditions, are entirely ignored. Under these circumstances, no scientific accuracy can possibly be obtained. But provided each fuse wire were rated at a certain length, and for use under certain conditions, I see no physical or other possibility of great variation between fuses. Nevertheless, the subject is so uncertain and so many engineers express their lack of confidence in the whole matter, that it is well worthy of consideration.

The Chairman.—That point, however, would relate rather to the question of fuses blowing sooner than they should, instead of not blowing when they should. It is those which do not blow when they are expected to trat rabe given fuses the reputation of unreliability. It is the fuses which carry two and three and four times their normal current, that electrical engineers are suspicious of, and not the fuses which blow too easily, although, of course, the latter is not desirable. A fuse
VII.] should not blow below its rated current. At the same time it is not those which have given the bad reputation to fuses. I have heard hundreds of times of fuses carrying a multiple of the currents that they were intended for, and a large multiple at that.

VIII.]Of course, in safety devices, on general principles, it is much better to have them act too soon than too late, as, for example, a safety valve.

IX.] Copper has a minimum specific resistance, and would have the minimum surface. That, I think, would make up for considerable difference in temperature. It has also been pointed out that, since copper has a very high temperature of fusion, the danger of setting fire to adjacent bodies is much greater when it does melt. But the low melting point alloys produce an arc when they blow, and, furthermore, any fuse should be wound.

X.] Mr. Howell.—Mr. Chairman, in practice, what fuses are called upon to go at a slight increase of current over their normal current?

XI.] The Chairman—There are two classes of fuses, but if I were asked to give examples of fuses that are called upon to yield at a certain definite current I would be puzzled to name them.

XII.] Mr. A. E. Kennelly.—I do not quite agree with Mr. Emery, that copper wires make the best fuses. It is often very convenient to use a copper wire for a fuse, but the difficulty with the copper wire is frequently that if you wish to employ a sensitive fuse that shall melt at only a small margin above its rated capacity, you must operate that copper wire red hot under normal conditions, in order that it shall melt at a reasonably small percentage above normal, and I think that has been the principal objection to copper wire fuses up to the present time.

XIII.] Copper wire fuses, on the other hand, melt at say, 1,050 C., which is a comparatively high temperature. Even granting the existence of a larger temperature coefficient of resistivity, the wire will have to be maintained at a comparatively high temperature by the normal current strength if it is required to melt at a small overload. In point of fact, the temperature coefficient of copper does not seem to differ greatly near red heat from its value at the boiling point of water, and in some cases it would be necessary to keep the wire at 500 C., or about red heat under working currents in order to effect fusion at a comparatively small excess of current.

XIV.] Mr. R. T. Lozier.—I think one of the most important points that Prof. Stine has called attention to is conclusion 3, that is to say, frequently renewing the fuses. I know when I was connected with the Edison company that the oxidation of the fuses in the street circuit boxes was rectified by changing the alloy to overcome that objection. I know that in practical experience, that point of changing the fuses is one that is seldom recognized. It is one that I did not know myself. I think that that one fact alone is a very important one to the profession.

XV.] Mr. T. Wolcott.—I think that conclusion 3 is quite an important one—that on important circuits fuses should be frequently renewed. If a fuse is run up to its rated capacity all the time that certainly is very important. The metal will change of course. That is shown in the paper here how the metal changes when the current is turned on. You certainly find
XVI.] That in ordinary fuses. I think the Chairman is entirely right in this matter. An instance of the trouble you generally find in fuses is this: If there is a fuse for a single light in the base of the lamp it sometimes will stand more than the plug that supplies the whole room, that is, the plug will blow and put out all the lights in the room, instead of the single light fuse blowing.

PROPERTY OF FUSE METALS WHEN SUBJECTED TO SHORT CIRCUITS. A PAPER READ BEFORE THE NIAGARA FALLS MEETING OF THE A. I. E. E.

BY WALTER E. HARRINGTON.

XVII.] The natural conclusion arising from a knowledge of the above data, is that fuse metals are under no circumstances to be considered in the light or nature of a protection.

DISCUSSION OF MR. WALTER E. HARRINGTON'S PAPER.

XVIII.] Capt. Wm. Brophy.—Nearly every point in this paper been covered, and discussed, except the concluding paragraph. I must say that I am nearly in accord with the writer in what he there says. I would simply amend it in this way: "The natural conclusion arising from a knowledge of the above data is that fuse metals are, under most circumstances," etc. It has been my province to deal with fuse metals for the last twelve years. The functions which are required are prevention of an abnormal flow of current over the wires, thereby increasing their temperature to a dangerous point. I have only very recently tested commercial fuses —sent out and bought them—and I find that none of them come anywhere near doing what they are advertised to do. The current that they carry varies from 50 per cent. to 250 per cent. above what they are marked. Many of them have the same property as copper wire—they heat; and I have maintained them in a red hot condition for ive or ten minutes or longer, if I so desire. I would like to see something substituted for the present commercial fuse, for a great many reasons. The men in charge of large plants are apt to use fuse metals that are entirely too large, even if they did what they are supposed to do, protect the wires in which they are inserted. As they age, I find that their carrying capacity increases very rapidly. In fact, there are innumerable objections that could be stated to the use of fuse metal for the protection of wires and prevention of overheating the same if time permitted.

XIX.]Prof. F. B. Crocker.—Any fuse would carry an infinite rent for an infinitesimal period of time; or, to put it a little more practically, it would carry a very great current for a very short time.

XX.] Mr. Blodgett.—The shape of the fuse has also an important bearing on the temperature at which it will melt. If it is in the form of a flat strip it will carry a higher current than if it is in the form of a solid rod or circular wire, particularly if it be intended to carry a larger current.

Editorial in the Nov. 20, 1895, issue of "The Electrical Engineer," entitled "Untrustworthy Electrical Mechanism."

XXI.] A survey of the work accomplished by the electromagnet would seem to demonstrate that, as a prime mechanism, pure and simple, it leaves little to be desired as regards faithfulness and accuracy of work. The trouble that has been developed occasionally in the past may almost invariably be traced to bad auxiliary mechanism, which has caused the condemnation of entire classes of apparatus embodying electro-magnets in their construction. We need only to refer to the early use of electro-magnetic cut-outs in electric lighting work and their abandonment in favor of the fuse. Yet it is doubtful if a more untrustworthy device can be found in the whole range of electrical applications, in proof of which we need only refer the reader to the elaborate tests of Prof. W. M. Stine, and associates, given in their Institute paper now appearing in our columns. As a result, we note a decided tendency to revert to the "old reliable" electro-magnetic cutout."

Synopsis of paper read before the National Electric Light Association in Washington, on "Some of the Faults Inherent in Fuse Metals":

XXII.] 1. Lack of uniformity in proportions and mixing the constituent alloys of the fuse, also in the methods of drawing the wire to a uniform geometric cross-section, and in preparing the fuse for the market. 2. Lack of uniformity, in practice,

in the actual placing of the fuse, in the following particulars: (a) Length of fuse for a given service. (b) Mass of the terminals used. (c) Position of fuse, as to whether it be vertical or horizontal. (d) Environment, as to whether it be held in suspension between terminals, or be allowed to lie along its entire length upon a mass of heat-radiating material, and whether it be open to the air or enclosed in a chamber. 3. Deterioration caused by: (a) Recurring abnormal currents. (b) Oxidation from various causes. (c) Disintegration from local voltaic action. 4. Impairment of contacts at terminals, due to loosening of the clamps from temperature expansions and contractions, or to mechanical or electrical causes. 5. The "Peltier" effect. 6. The abuse of acceptable (?) fusing devices, by substituting for the metals designed to be used in them others that are unsuitable. 7. Time element. Practice has demonstrated that fuses rarely, if ever, "blow" in time to accomplish the object for which they are placed in circuit. There is also a wide range of uncertainty as to the constancy of this period for any given fuse. 8. Capacity of the ordinary fuse wire to pass current far in excess of its rated blowing capacity for a period of time sufficient, in a majority of cases, to cause damage to some portion of the circuit.

A letter by Mr. Walter E. Harrington to "The Electrical Engineer," Nov. 27, 1895:

"Mr. James H. Bates' letter in "The Electrical Engineer" of Nov. 20, is more interesting to me than mine was to him, as he agrees with me that magnetic circuit breakers are a necessity, as would be implied in his statement: 'The magnetic circuit breaker is essential in a case like heavy railroad work, where a circuit breaker controls a large volume of current.'

"Mr. Bates makes light of the fuse protection of jaws of switch to prevent blistering of the contacts, and to emphasize this triviality (?) he more prominently identifies himself in favor of magnetic circuit breakers, as the following statement shows:

XXIII. To weigh such a comparatively trifling (?) matter against so great an advantake as pointed out is extreme folly, for what does a little blistering amount to, compared with the safety of apparatus?"

"What Mr. Bates seems to think an insignificant matter, and, as he states, 'may be remedied by proper design' has been the opinion of several engineers with whom I have discussed the matter of magnetic circuit breakers. Yet why is it not done? The answer is simple. I have been three years reading papers based on practical tests of different kinds to demonstrate the gross untrustworthiness of fuses. Engineers at large are wedded to the old time fuses. Only one month ago, in conversation with one of the most prominent electrical engineers in the East, he stated positively, as his opinion, 'he did not see wherein anything was gained by using magnetic circuit breakers on a railway switch-board, let alone on cars.'"

"He further stated, that a fuse and a magnetic circuit breaker of equal capacity would, in event of a short circuit, permit the passage of the same volume of current. As long as our prominent engineers keep ignorant of the practical behavior of fuse metals (I would here refer to Prof. Stine's and associates' paper on "Behavior and Rating of Fuse Metals," read recently before the A. I. E. E.) just so long magnetic circuit breakers will not be used generally."

"I felt, when I prepared a paper on the behavior of fuse metals on 500-volt short circuits, that when it would be presented to such an august body as the A. I. E. E. it would be taken in the spirit presented. But when such engineers as Prof. Elihu Thomson, C. P. Steinmetz and others, lost sight of the salient facts contained in the paper and discussed methods employed, and in some cases praised fuses—well! The only engineers who, by their discussion showed a realization of the facts were Prof. Crocker and Captain Brophy."

"Here and there an engineer stands out in favor of magnetic circuit breakers for general use. I might mention Dr. Cary T. Hutchinson, C. O. Mailloux, Mr. Tapley, of the United States Printing Office; Mr. Chas. Hewitt, and others. In conclusion, I must add one more name to the list—Mr. James H. Bates."

LESSONS.

1. Fuses carry 50 to 200 per cent. current in excess of rated fusing current.

See:—Tests, also paragraphs VI., VII, page 10; paragraphs XVI. page 12; paragraph XVIII., page 13; paragraph XIX., page 14; paragraph XXII., page 15.

2. Under "Short Circuits" a fuse will carry excessively abnormal currents:

See tests Nos. 1, 3, 6, 7 and 38.

See paragraph III., page 8; paragraph IV., page 8; paragraph XVII., page 12; paragraph XIX., page 14, and paraprаph XXII., page 15.

3. Fuse metals made of alloys, so as to have a low temperature melting point, will maintain at a red heat, making a serious fire risk.

See tests Nos. 3, 4, 5, 8, 12 and 33. See paragraph XVII., page 16.

4. Metals such as copper, aluminum, iron, etc., are not adapted for fuse metals, owing to the high temperature required for fusing. To be reasonably sensitive, they must be maintained at a red heat, which is not permissible, owing to fire risk.

See paragraph IX., page 10; paragraphs XII., XIII., page 10; paragraph XVIII., page 13.

5. Fuse metals arc and make a serious fire risk. See tests Nos. 14, 15, 19, 21, 34, 23, 35 and 37. See paragraph IX., page 10.

This phenomenon was very pronounced, using different length fuses, and, placing fuse blocks in different positions. In my judgment, this is a fault inherent in fuse metals, due to the fact that the molten metal can still carry current and the arcing will jump the slight distances intervening between the terminals and the molten metal, although an arc can be maintained without the presence of the molten fuse metal.

6. Enclosing a fuse is not safe, as the gases generated upon the fusion of the metal will continue to carry the current in event of a short circuit. See paper read before the American Street Railway Association at Atlanta, Ga., entitled, "Destructive Arcing of 500-Volt Fuses."

7. Fuse metals are very sluggish in fusing, and in this one factor make a serious fire risk, as the current flowing in many instances permits the wire under insulation to become hot or intervening space between wires, if a leak arises, to become hot. See test Nos. 34, 35, 36 and 37. See paragraph I. page 8; paragraph II, page 8; paragraph IV., page 8; paragraph XXII., page 12.

8. Fuse metals are generally unreliable, as their position, length, age, oxidation, shape, composition, temperature, terminals, all affect their fusing point. No standard fuse block and fuse could be established, but what some of the above factors would enter in to cause a variance in the result. See tests 28, 29, 30, 31, 32 and 33. See paragraph IV., page 8; paragraph XIV., page 10; paragraph XVIII., page 13; paragraph XX., page 14; paragraph XXI., page 14; paragraph XXII., page 15. (The page numbers refer to MSS report.)

REMEDY.

Attempts were made in the early days of electric lighting to use automatic magnetic circuit breakers in place of fuse metals. Owing to the lack of proper mechanical design of these early electro-magnetic safety devices, their use was abandoned. In the last few years, however, as a substitute for fuses, automatic magnetic circuit breakers have been adopted in power transmission, railway work, isolated lighting plants, and storage battery installations, independently of any requirements of boards of fire underwriters, as engineers have long realized by practical experience the untrustworthy character of fuse metals. I would here refer to the editorial in "The Electrical Engineer," in paragraph XII. of this report. I have made a careful detailed investigation, visiting power stations where the modern magnetic circuit breakers are used, and have also made personal tests; while I have found certain faults in the design and mechanical construction of some of the magnetic circuit breakers now in use, in no instance are those faults comparable to the more serious inherent faults in fuse metals. An automatic magnetic circuit breaker depends for its action upon the magnetic quality of the current. This action is instantaneous. (A fuse depends for its action upon the heating quality of the current. This action is necessarily slow, and it is inherently foreign to the purpose the fuse is intended for, to wit—protection.) I believe automatic magnetic circuit breakers should be employed to protect all circuits of over 10 amperes capacity.

After carefully considering the several features in principle and design of automatic magnetic circuit breakers, I would consider that an automatic magnetic circuit breaker embodying the following particulars would be an entirely satisfactory electro-mechanical device for the protection of electric circuits. 1. A magnetic circuit breaker, wherein no springs are permitted in its adjustment. Adjustment should be effected by means of distances. 2. Magnetic circuit breakers should have the feature of opening the circuit in less and less time, as the conditions of the circuit protected approach a short circuit. The electro-magnetic part of circuit breakers should be designed to develop more energy than is necessary to trip retaining catch. The additional energy developed should be applied directly to aid in opening the switch. It immediately follows from this that as the current flowing through the device exceeds the amount of adjustment, the switch, will of course be more quickly and positively opened.

3. The magnetic circuit breaker should be so constructed that, with the minimum current flowing through it necessary to open it, the blow struck or power exerted by the plunger or armature should, if it moves at all, under conditions, be such that the switch will open.

4. The electro-magnetic mechanism wherein any insulation enters into the construction of the trigger or catch, should not be permitted, owing to the tendency of the insulating composition to ultimately break down.

5. It would seem desirable to have the magnetic circuit breaker so constructed, that, in event of the circuit breaker opening, owing to overloaded condition of circuit, if same overloaded condition continues at the time circuit breaker is thrown in, the catch will not engage.

6. Where magnetic circuit breakers are to be employed in damp places, all bearing pins and parts liable to be affected by rust, should be of phosphor bronze, and moving iron parts plated.

7. The armature or plunger of the magnetic circuit breaker should not be permitted to act on the retaining catch or switch arm, without a free preliminary movement preceding such action. The reason for this is apparent, as the adjustment would be then effected by the friction of catch or arm.

In conclusion, to condense the above features to form a specification to cover what would constitute an "approved" automatic magnetic circuit breaker, I submit the following: An "approved" type of automatic magnetic circuit breaker must embody the following features:

1. The magnetic circuit breaker must have the features of opening the circuit in less and less time as the conditions of the circuit protected approach a short circuit, that is, have an inverse time element. The electro-magnetic part of circuit breakers must be designed to develop more energy than s necessary to trip the retaining catch. The additional energy developed should be applied directly to aid in opening the switch.

2. A magnetic circuit breaker wherein no springs are permitted in its adjustment.

3. Insulation must not enter into the construction of the trigger or catch.

4. All bearing pins and parts liable to be affected by corrosion or rust must be of phosphor bronze, and moving iron parts copper plated.

5. The armature or plunger of the magnetic circuit breaker must not act on the retaining catch or switch arm unless a free preliminary movement precedes such action.

ELECTRIC TRANSPORTATION.

THE DUBLIN-DALKEY ELECTRIC TRAMWAY.[1]

THE conversion of the original horse tramway between Dublin and Dalkey into an electric line having now been practically completed, and successful trial runs of cars over a portion of the line having already taken place, the interesting event of the inauguration of this line may be expected shortly to occur. The line is owned by the Southern District Tramway Company, of Dublin. Starting from Dublin at a point about half a mile north of Balls' Bridge, where the generating station is situated, the line passes through Donnybrook, Williamstown, Blackrock, Kingstown—where a branch traverses streets leading to the harbor—and thence to Dalkey. Throughout the greater part of its main route the tramway is roughly parallel with the Dublin, Wicklow and Wexform steam railway.

Acting upon the advice of their consulting engineer, Mr. J. Clifton Robinson, the Tramway Company gave the contract for the electrical equipment of the line, the reconstruction of the track and of the buildings for the power station and substations, and the erection of the generating plant, &c., to the British Thomson-Houston Co. The track, which is 7¾ miles in length, is on the whole, fairly level, the principal gradients being 1 in 16, 1 in 23, and 1 in 29. It is double throughout, except for a short distance in two places. The gauge is 5 ft. 2 3-16 in., and the rails, which are of 76 ℔. size, with massive fish-plates, are laid in concrete. The electrical equipment of the track is upon the overhead trolley system, span wires being principally used, with center poles in some of the narrower streets, and along the chief road through which the Kingstown branch passes. The style of the center poles is shown in Fig. 1, from which it will be seen that these are far from being inartistic. Indeed, the appearance of the center poles, with double brackets is undoubtedly superior to that of the plainer side poles, with their numerous span wires crossing the streets at right angles. The return current is through the rails, which are bonded on the Chicago plan, single bonding being used throughout, with cross-connections at every 120 ft. The trolley wires, which are duplicated throughout, are of hard-drawn copper, 320 mils in diameter. The poles, whether for the central or side construction, are of steel tubes in three sections, with hot-shrunk overlapping joints. They are grounded to a depth of 6 ft. in concrete, a cast-iron base and footplate being fitted over the lower end of the pole. At the ends of each half-mile section, section insulators are used; and here the ends are connected to rubber-covered cables leading down the poles to the switch pillar, in which there are switches, by which the sections may be connected to the continuous-current feeders. These switch pillars are erected along the route, beside the vehicular way; they are of cast iron, and in general appearance resemble postal pillar boxes, except that they are of a more ornate design. They are 4 ft. in height and 18 in. in diameter.

One of the most interesting features of the Dublin-Dalkey tramway system consists in the adoption of power transmission by means of polyphase currents, between the power house and the two sub-stations which feed the line en route. The position of the power station would have rendered it difficult to comply with the Board of Trade regulation in regard to the drop of pressure on the return circuit through the rails, except by means of sub-stations at the far end and an intermediate point on the line. This regulation insists that the fall of pressure on the entire length of the return circuit shall not exceed 7 volts. It was, therefore, considered desirable to adopt polyphase transmission between the power station and the two sub-stations, the one at Dalkey and the other at Blackrock. The sites for the main and secondary stations

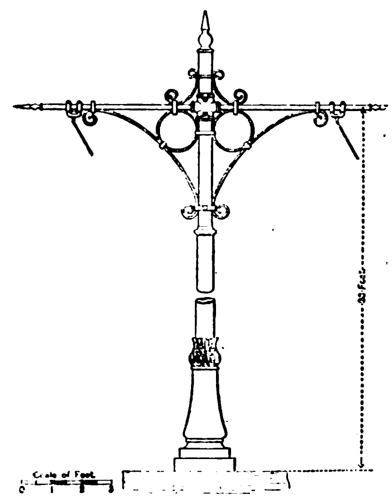

FIG. 1.—CENTRE POLE BRACKET, DUBLIN–DALKEY TRAMWAY.

were fixed by the existence of car sheds and stables, belonging to the original horse tramway system, at these places; and the old buildings on these sites have been partially utilized and reconstructed to suit their present purpose.

The power house is situated on the banks of the River Dodder, which provides water for condensing purposes. The equipment of the power house provides plant for directly feeding the nearer end of the line with continuous current at 500 volts; as well as for transmitting three-phase power, at from 2,300 to 2,500 volts, to the distant sub-stations. The arrangement of the station equipment is shown in Figs. 2 and 3.

In the boiler house there are some interesting features. There are three Babcock-Wilcox boilers, each provided with double steam drums, of 250 H.P per boiler. These develop a normal pressure of 140 ℔. on the gauge. The boilers are fired mechanically, by means of Vicars stokers; and the gear for these stokers is driven by a G. E. shunt motor, which also drives the scrapers in the Green's economizer. The feed water is supplied either by means of an injector, or by two three-throw pumps, made by Messrs. Daniel Thompson & Co., each of which is driven by a G. E. motor, of the same type as those used on the cars, but shunt wound. All the motors in the boiler house are worked from the bus-bars, at 500 volts, through special rheostats and switchboard. The feed pumps are capable of supplying 16,000-℔. of water per hour.

In the machinery room there are at present four generating sets, each driven by a 150 B. H. P. Willans (H. H. S.) compound condensing, two-crank engine, running at 380 revolutions per minute, with steam at 140 ℔. The engines have been specially strengthened to stand the severe loads which traction work temporarily imposes and will develop 175 B. H. P. for a short time on occasion. The engines are adapted to belt driving,

[1] London "Electrician."

each being provided with a 3 ft. 10 in. flywheel pulley, and with an outer bearing. Two of the engines drive two "B. T. H." 100-kilowatt four-pole tramway generators at 625 revolutions per minute. These are compound wound for 500 volts at no load and 550 volts at full load. The other two engines are belt coupled to two eight-pole, three-phase generators, each capable of developing 120 kilowatts at from 2,300 to 2,500 volts, running at 600 revolutions per minute. These machines were designed by Mr. H. F. Parshall, and were manufactured at Newcastle-on-Tyne by Messrs. Armstrong, Mitchell & Co. In addition to these four generating sets, there is a "B. T. H." four-pole motor generator of 30 kilowatts capacity, consisting of a 500-volt shunt motor direct coupled to a 125 to 140-volt continuous-current generator for supplying the station lights and charging the storage batteries. This motor generator is situated at one corner of the machinery room, in line with the dynamos, as shown in Fig. 2.

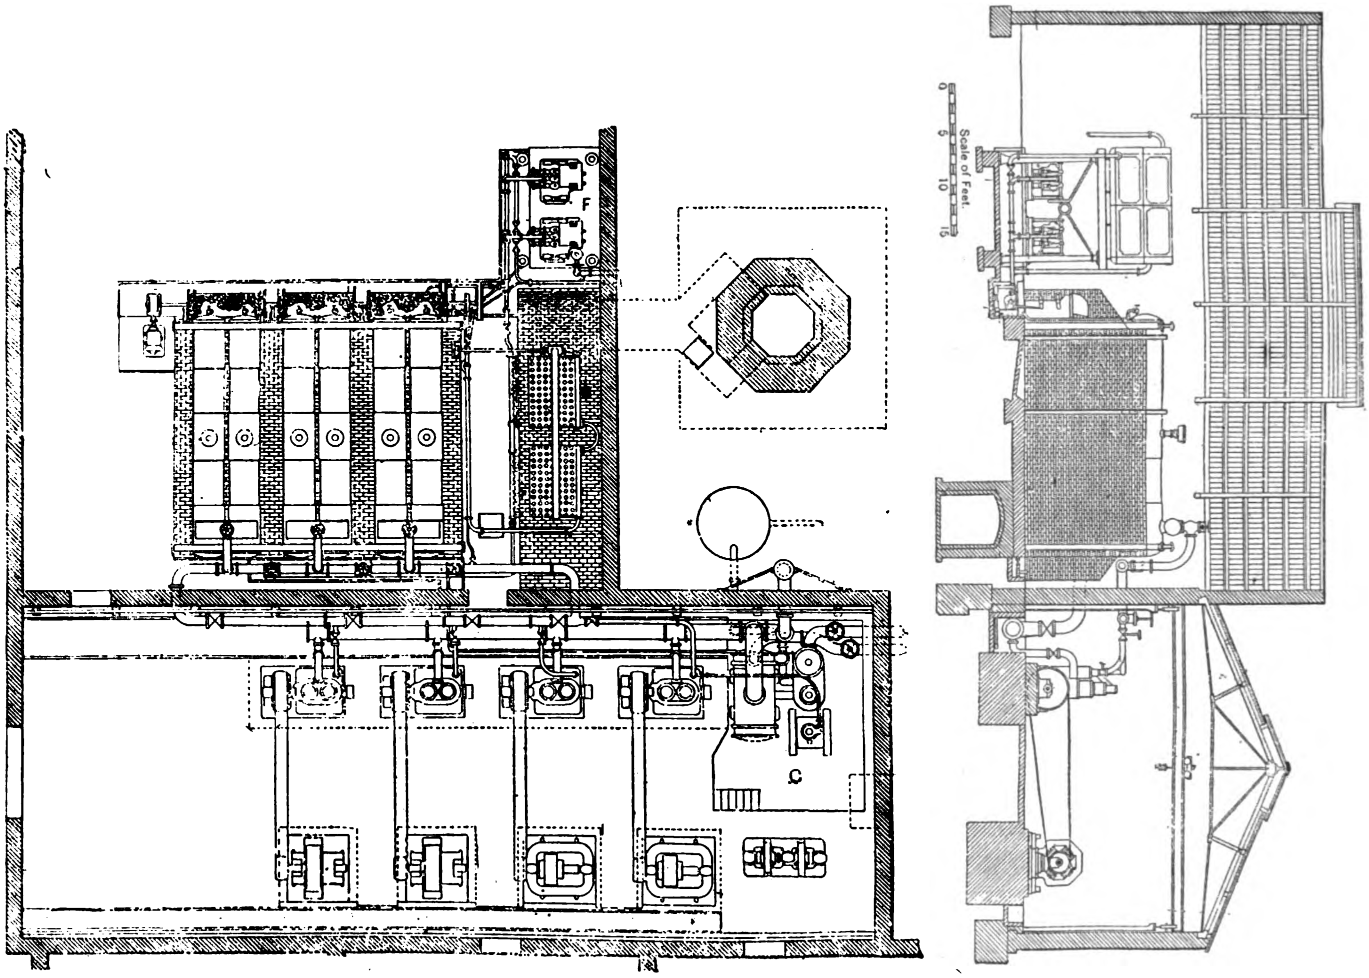
The accumulators are of the Epstein type, there being 55 cells of the R 11 pattern, having a capacity of 600 ampere-hours.

The repair shops are fitted with a complete set of machine tools, consisting of lathe, shaping machine, drill press, hydraulic press, grindstone, blacksmiths' forge, &c., and a full equipment of small tools. The machine tools are driven by belt from a counter-shaft operated by a "G. E." shunt-wound motor, run off the 500-volt circuit. The testing room contains the usual testing instruments, a battery of 50 small accumulators, and a portable Silvertown set.

The present rolling stock comprises 20 motor cars, each double-decked and capable of seating 20 passengers inside and 30 on top, the length inside being 16 ft. 6 in., and over platforms 27 ft. 2 in.

At the Blackrock sub-station the plant consists of two direct-coupled units, each consisting of a synchronising motor, coupled to a 60-kilowatt continuous-current generator. The motor receives the three-phase current at about 2,300 volts pressure, and the generator produces current at a pressure of 500 to 550 volts. Suitable switching gear is provided to enable the generator to be started from the trolley wire feeder to run the motor before throwing it into circuit. There is also a set of switching gear for controlling the direct-current generator, and connecting it to the 500-volt trolley wire feeder. The plant at the Bullock Hill sub-station, at Dalkey, is similar, except that the generators have a capacity of 50 kilowatts each.

Current is carried from the power house by two sets of feeders, one being for the 500-volt direct current, and the other for the 2,500-volt three-phase system. The 500-volt feeders, which supply current to the overhead trolley wire, consist of Callender's lead-sheathed armored cables of 0.08 sq. in. and 0.15 sq. in. section. The former cable extends from the power station as far as Blackrock sub-station, but the latter, of course, extends to the Bullock Hill sub-station. The three-phase current is carried from the power station as far as Blackrock sub-station by two triple concentric cables, each of 0.0496 sq. section, and from thence to the Bullock Hill sub-station by one triple concentric cable of the same section. These concentric cables are of the British Insulated Wire Company's lead-sheathed and armored type. In addition to these feeders there is a three-core Callender lead-sheathed and armored cable, one conductor of which is used as the test wire. The other two conductors are for the telephone system. This cable is led into the feeder switch pillar, and connected to telephone instruments placed at every half-mile along the line, and is also carried into the power house and sub-stations, where telephone instruments are fixed.



FIGS. 2 AND 3.—DUBLIN-DALKEY ELECTRIC TRAMWAY POWER STATION.—PLAN AND SECTION.

BRIDAL TOUR BEGUN ON TROLLEY.

It is something of a novel sight to see a bridal party riding through the country on a trolley road. At the great Borden farm, at Wallkill, N. Y., twelve miles back of Newburgh-on-Hudson, where condensed milk is manufactured, Miss Nellie Borden, daughter of Gail Borden, the owner of the condensary, and Mr. Hamilton, of New York, were married. After the wedding some thirty friends who were present escorted the newly wedded pair to the Newburg and Walden trolley road, a short distance away, and started them off on their novel bridal tour.

AIR BRAKES AND ELECTRIC BRAKES.

AN interesting editorial discussion of the present status of street car braking appeared in the London "Electrical Review" of December 27, the text being the paper presented by Mr. E. J. Wessels at the Montreal Street Railway Convention. We have been favored by Mr. Wessels with a copy of his reply to some of the comments of our contemporary, and publish below the letter written by him as general manager of the Standard Air Brake Company.

Sir:—While sensible of the honor you do our general manager quoting so freely from his Montreal address, we are sure you will not consider it amiss if we should make some comments on your article, especially its closing sentence, which says: "One would not wisely endeavor to apply an electric brake to a steam locomotive, nor does it seem any more desirable to get up air pressure on an electric car for brake purposes."

We cannot assent to the argument. We do not think the analogy is sound. If anything has been settled about the latest practice in the United States, it has been the fact that the successful electric brake is yet to be born. Further, those electric brakes which were so freely brought to the public notice have been obliged to retire from the field. Even the remaining electric brake now being advertised is not what it should be. It will take considerable cash, labor and time before it becomes commercial. In view of this, you are quite justified in saying "One would not wisely endeavor to apply an electric brake to a steam locomotive."

With the air brake, however, the conditions are vastly different. We do not use steam to generate pressure, but in most of our installations depend either (directly or indirectly) upon the car axle for compressed air. By means of patented improvements the pressure cuts in and out automatically, so that the amount of power consumed is very small. When the compressor is cut out there is positively no power consumed.

In the first paper the writer had the honor to present before the American Street Railway Association in Atlanta (in October, 1849), he pointed out reasons why air brakes are destined to supercede all other forms of brakes and why they are more reliable than electric brakes.

To reproduce that article would consume too much of your space, but as the address has been extensively reproduced here and abroad, your readers will have no difficulty in referring to it for points.

For braking cars operated at extraordinary speeds we furnish our electric compressor type. For running its slow speed series wound motor we tap the motor wiring of car. For our most exacting requirements, even when compressor-motor is running at its highest capacity, we consume scarcely as much current as is required for two ordinary lamp circuits. It is only in very exceptional cases that the compressor-motor will run at this rate for more than a few minutes at a time.

It has been demonstrated here that one cannot rely upon the electric brake as certainly as upon the air brake. Without going into an elaborate argument, it is obvious that special reservoirs filled with compressed air, available for making 100 or more stops, will always prove a greater source of safety than other forms of apparatus, far more liable to get out of order.

You state "The general impression conveyed by the paper and discussion is that, so far, air brakes have not been found altogether successful in American tramway work, but that their need is greatly felt." In his paper writer certainly understated the merits of air brakes rather than risk over-stating them. The paper, while it did not advance the idea that perfection had been reached in air brakes, distinctly stated that there was one type of commercial air brake in existence.

The Westinghouse air brake (which made its bow to the public twenty-seven years ago) is not absolutely perfect, but, as writer showed in Montreal, it has saved thousands of lives and millions of property. Moreover, our street railway air brakes have proved altogether successful, and you seem to have misunderstood the article in judging otherwise. You state: 'To-day there is not an air brake in St. Louis, although in that city they had a splendid start," etc.

We can best answer that by quoting verbatim from an advertisement we inserted in "The Street Railway Journal," December, 1895, under heading, "A Point About Discussions." We quote therefrom as follows:

"That was a most interesting discussion which followed Mr. Wessels' paper on 'The Present Status of the Air Brake,' read before the Montreal Convention. He distinctly announced that his paper was not written for advertising effect. Nor would he violate professional etiquette by mentioning any names.

One St. Louis manager stated several objections had been made to air brakes on a road in his city.

He should have made clear, but failed to do so, the fact that those air brakes were not ours, nor have we ever had any connection with them, near or remote. The comical part is that the air brakes the gentleman referred to were never used on his road. He spoke only from "hearsay." No court of law receives such testimony as evidence. Neither should you, at least without ascertaining the facts in the case.

The truth is, these obsolete air brakes were in Mr. Wessels' mind when he read from his paper: "There were air brakes which entered the lists at the last convention which have retired from the field; some are still bearing the heat and burden of the day. It is a case of the survival of the fittest. Our air brakes are 'bearing the heat and burden.' "

In replying to the gentleman, Mr. Wessels showed that the St. Louis and Suburban Road was the one on which the air brakes referred to were operated, and that they felt the need of air brakes so badly that they themselves rebuilt those which broke down.

And since then that air-brake system has become obsolete. These brakes were manufactured in the West. Ours are manufactured in the East, and remain. We are still doing business at the old stand.

By the way, wouldn't it have been far more interesting for the convention to have heard directly from some one connected with the road to which the gentleman referred instead of listening to an outsider who could not speak officially about what he didn't know except at "second hand"? I think so.

As illustrative of the perfectly successful operation of our air brakes, we ask your attention to the article in "The Street Railway Journal" for February, 1896, in which you will observe a number of cuts of cars being successfully braked by the "Standard." We also send you under separate cover an electro of a heavy car used on the Pacific slope, which you will, perhaps, be kind enough to reproduce with this letter.

We are now filling the third order from that road. Had our air brakes not been successful the buyers would not have, after a year's trial, sent us the third order to equip twenty-eight additional cars.

But perhaps the best evidence of the success of our air brakes is the fact that hundreds of them are in satisfactory operation around the globe. Modesty kept the writer from mentioning that fact on the convention floor.

ANOTHER MOTOCYCLE RACE.

The "Cosmopolitan Magazine," in its February issue, publishes the details of its offer of $3,000 in premiums to be awarded to motor carriages presenting the greatest number of points of excellence as exhibited in a trial trip, to be made on Decoration Day, May 30, next, from City Hall Park, N. Y., to the Cosmopolitan Building, Irvington-on-Hudson, N. Y., and return, a round trip of fifty-two miles. The award will be made on the following points, the maximum being 100: Speed, 50; simplicity and durability of construction, 25; ease in operating and safety, 15; cost, 10. Entries are to be made before May 1. The names of the judges will be announced later.

The route selected is "along Broadway to Central Park, through the park to Washington Bridge, thence along Broadway continues to Yonkers, where the course will include five miles of asphalt pavements; then following the country Broadway to Irvington, paralleling the Hudson and passing through one of the most beautiful regions of America. The roadway over which the trial will be made is not excelled even in France."

An article in this issue of the "Cosmopolitan" on "The Progress of the Horseless Carriage" shows illustrations of the "Electrobat," an electric brougham and an electric delivery wagon, and mentions the Holtzer-Cabot vehicle, as well as illustrating and describing other methods of propulsion.

THE "MOTORMAN'S POSE."

What might be called a "motorman's pose" has been developed by the trolley cars, according to observations made at a ball given by the trolley motormen in Worcester, Mass. It is alleged that while resting between the dances every motorman stood on one foot. When running a car the motorman must stand on one foot and have the other free to pound the gong, the gong being pounded incessantly, as any Brooklynite will testify. Thus a necessity of work has developed into a habit at all time. This is a subject for the consideration of the evolutionists.

THE TROLLEY AND THE READING ROAD.

The annual report of the Philadelphia and Reading road, just issued, states that the competition of suburban electric roads had decreased the earnings from passenger traffic $178,887. There was a decrease in short-distance travel, and an increase of passenger for long hauls.

POWER TRANSMISSION.

RECENT GENERAL ELECTRIC MINING APPARATUS.

THE General Electric Company has, since it first entered the mining field, kept steadily in view the improvement of its electrically operated apparatus

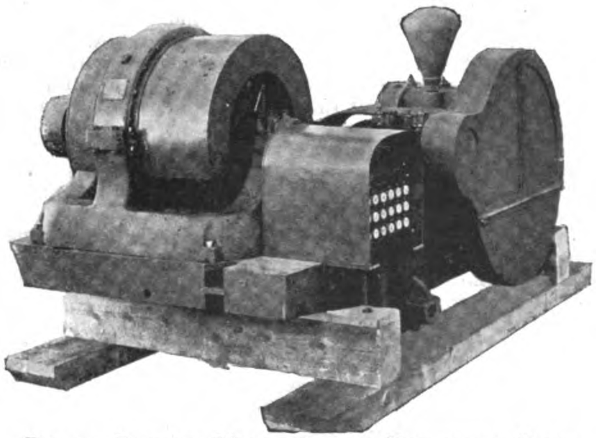


FIG. 1.—ELECTRIC MOTOR DRIVING HORIZONTAL PUMP.

for that class of work and its adaptation to the special conditions of the mining industry. The illustrations herewith show a few examples of recent appliances produced at its works and now in successful operation.

Fig. 1 shows a $6\frac{1}{2}$ inch by 8 inch horizontal triplex pump, directly driven by a 10 horse power, four pole slow speed motor through two reduction gears, the entire combination on the same base being mounted on a truck for ready transportation from place to place in the mine. The motor is controlled by a rheostat set at the side and, like the motor, housed in with a sheet iron cover. The illustration shows the truck mounted on wooden base for shipment.

Fig. 2 shows a root blower driven by a four pole slow speed motor of 15 horse power capacity and mounted on a common base frame. Fig. 3 is a 60 inch steel plate exhaust fan operated by a $2\frac{1}{2}$ horse power four pole motor. The fan makes 480 revolutions per minute and has a capacity of 8,300 cubic feet of air per minute at $\frac{3}{4}$ oz. pressure.

The slow speed motors driving the above mentioned

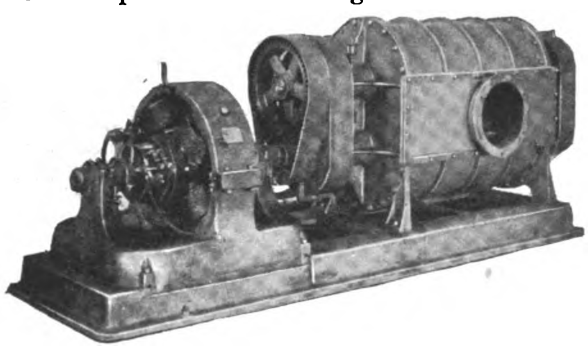

FIG. 2—ELECTRIC MOTOR DRIVING ROOT BLOWER.

apparatus are recent developments in the motor line, designed for use on direct current circuits. For outputs greater than 5 horse power, they present decided advantages over motors of bi-polar type. They are compactly built and admit of direct combination with machinery without greatly increasing the space occupied. They operate at slower speed than any other motors of similar capacity yet built, and although reduction of speed must necessarily imply increase of weight, in this case it appears to be amply compensated for by economy of material effected by the adoption of the four pole type. The frames and fields are of special soft cast steel, which, possessing high magnetic permeability, allows of the construction of a very light motor. The armatures are thoroughly ventilated; and the windings of copper wire, first

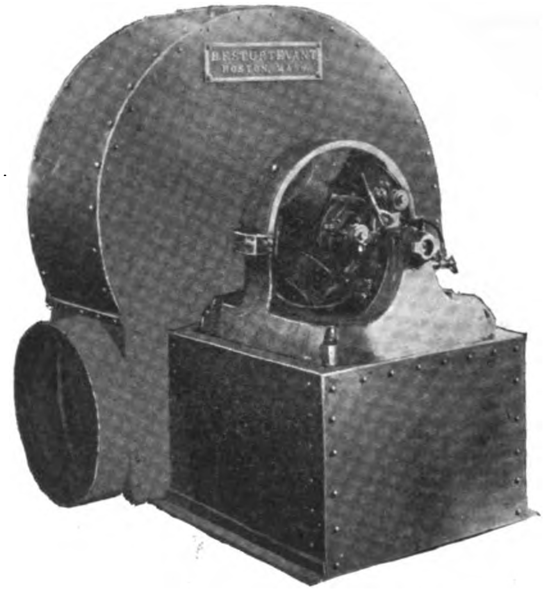

FIG. 3.—ELECTRIC MOTOR DRIVING 60-INCH EXHAUST FAN.

formed and insulated, are embedded in slots in the armature core, and bound down securely on the projecting flange of the armature spider. The coils can be easily removed and replaced. The machines are sparkless and the load can be varied from nothing to full load without the necessity of shifting the brushes. Precautions are taken to prevent any tendency on the part of the bearings to get out of alignment and proper contact of brushes with the commutator is insured by special construction of the brush holders.

Another combination, introducing the multiphase motor for use on alternating current circuits, whether monocyclic or multiphase, is shown in Fig. 4, illustrating a triplex vertical single action pump, directly connected to a 220 volt 60 cycle, ten horse power, multiphase motor. This type of motor developed by the same company, aside from its compactness, which allows of its erection in a restricted space, has the additional advantage of being absolutely without brushes, commutator or moving wires. It requires no

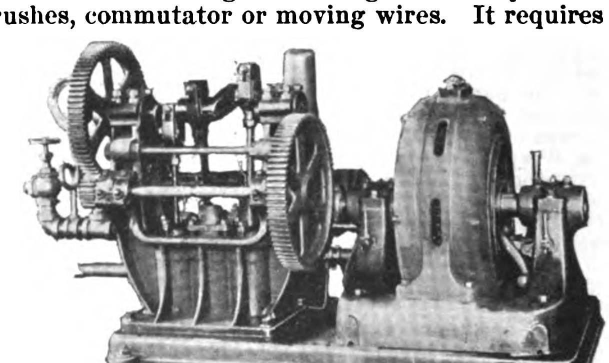

FIG. 4.—MULTIPHASE MOTOR DRIVING VERTICAL PUMP.

attention and may be stopped and started under full load or no load. These motors are now in use on all the three-phase monocyclic power transmission circuits in this country, operating without attention and without accident and to the entire satisfaction of the user.

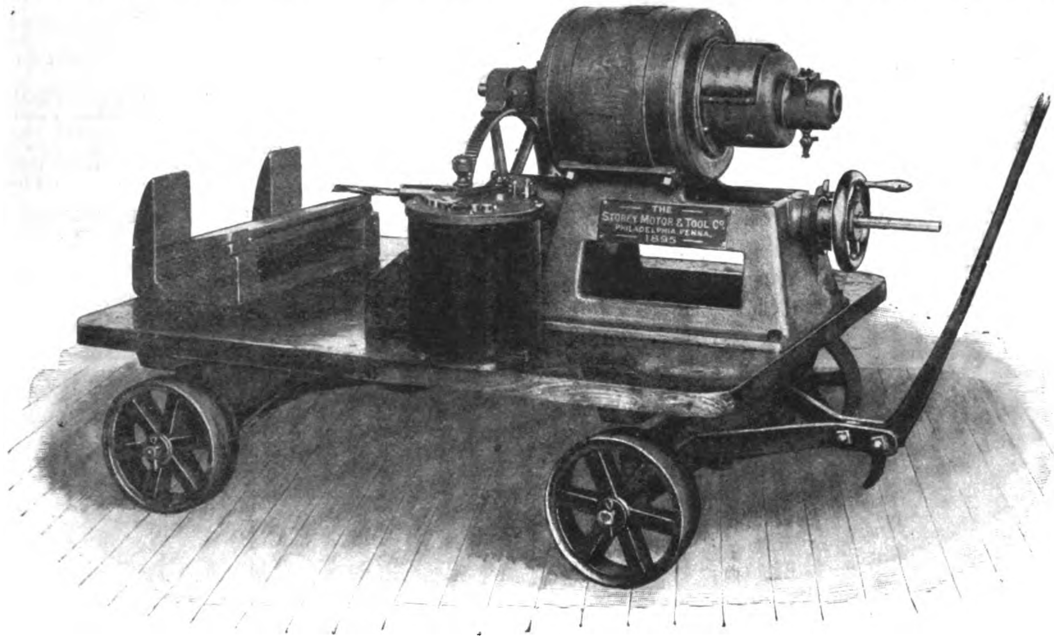
THE STOREY PORTABLE ELECTRIC DRILL.

THE STOREY MOTOR AND TOOL COMPANY of Philadelphia some time ago put on the market a compact and efficient portable drill, which we illustrate herewith. This machine is adapted for drilling pig iron and copper for test work, drilling rails and for various other kinds of work. Owing to the type of the motor, which is entirely enclosed, it is suitable not only for indoor work, but can also be used for outdoor purposes without requiring any specially arranged covering for its protection.

The outfit complete, illustrated in the accompanying engraving, consists of motor and drill combined, together with regulating rheostat, for obtaining any desired speed, and a drum with 100 feet of flexible cord, all mounted on a truck, with or without rack for holding material to be drilled, as desired. These machines drill in sizes up to 1½ inches in steel and 2 inches in cast iron, and are furnished with both automatic and hand feeds.

The rapid adoption of electricity in machine shops and factories makes a tool of this kind extremely useful, as it can be moved at will wherever it is needed. These drills can also be placed on a table or in any stationary position, and will cover a large range of work of different classes. As an illustration, two of these drills are mounted on bed plates, one at each end of a large callender roll, drilling two holes in flanges at the same time and tapping them in the same operation, before the roll is moved. Another adaptation of this drill is where it is fitted with a telescoping shaft and is used in yards for drilling holes in the construction of switches and crossings for street car and railroad work.

A different type of portable drill is being brought out by the Storey company and will be ready for the market in a few weeks.



STOREY PORTABLE ELECTRIC DRILL.

A MATHER POWER TRANSMISSION PLANT.

One of the latest large manufacturing plants to adopt electrical power transmission is the Keasbey & Mattison Company, makers of the well-known magnesia sectional covering, etc., at Ambler, near Philadelphia. This corporation has just closed a contract with the Mather factories, of Manchester, Conn., for a preliminary plant, consisting of a 60 kilowatt, 220 volt, multipolar generator and four slow-speed motors of 30 horse power capacity and less. One of the motors takes the place of an engine in an isolated department, where steam has been carried by a pipe, covered with the owner's magnesia covering. At the Keasbey & Mattison plant current is also generated for the town lighting circuit. This lighting plant has just been increased by a third Mather ring type dynamo.

THE CURRENT MOTOR COMPANY has been formed at Seattle, Wash., with a capital stock of $4,200, by S. T. Kelsey, Jr., J. M. Tenney, H. L. Reynolds, T. H. Barrow, and others.

NEWS AND NOTES.

DID A TELEGRAPH BLUNDER PROVOKE THE TRANSVAAL RAID?

An ingenious explanation of the action of Dr. Jameson is given by the London correspondent of the "Birmingham Gazette." According to this, Jameson, with his men, were waiting for some word from Johannesburg. It came in a telegram worded thus: "Revolution carried, in compliance with your desire." That was the telegram received. The telegram actually sent from the Johannesburg committee was, "Resolution carried, in compliance with your desire." That "v" instead of "s" made all the difference. Jameson made his plunge into the enemy's country, expecting to find the settlers in arms waiting for his coming. Instead, he found only great masses of armed Boers barring his way. The Boers were fully prepared, and expected his coming. This raises the curious suggestion. Had they anything to do with altering the telegram? Was it a trap for the English raiders to draw them on in order to justify the quaint vulgarism of Krueger that when the tortoise put out its head they would cut it off.

THE STRANDED "ST. PAUL" AS A TELEPHONE STATION.

Racing for home last week, the magnificent American liner, "St. Paul," lost her course in a heavy fog and grounded in the sandy beach at Long Branch. There she has lain ever since, for although several tugs have pulled at her, she can say in the language of her apostolic namesake: "None of these things move me." One of the first ideas that occurred to the parties interested was to keep up communication between ship and shore, and this has been done telephonically, it being the first instance on record where a telephone has been installed on a shipwrecked vessel. A long-distance set has been put on board by the New York and New Jersey Telephone Company, and if you want to talk from New York or Chicago with anybody on the "St. Paul" all you have to do is to call up Long Branch—at least until she moves off and makes her dock.

ELECTRIC HEATING POPULAR.

According to "The Electrical Engineer," the reports are uniformly favorable to the success and desirability of electric heating of street railway cars. This is not only true of the New York City roads which use electric heaters, but is found to be true of roads over the country generally, so far as heard from. Certainly it is true of the local railway's experiment in that line, says the "Springfield Republican," looked at from the passenger's standpoint at least. The cars which employ the new method have never before been so satisfactorily heated as now.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JAN. 28, 1896.

Accumulators:—

SECONDARY BATTERY. P. F. Ribbe, Berlin, Germany, 553,596. Filed July 10, 1895.
A double electrode for storage batteries, composed of two plates of non-conducting material held together by an acid-resisting substance between them, which plates have curved recesses for receiving the active mass.

Alarms and Signals:—

LOW WATER ALARM. O. J. Backus, San Francisco, Cal., 553,636. Filed May 9, 1895.
An expansible bar serves to open or close an electric alarm circuit.

REGISTER. T. B. Dixon, Henderson, Ky., 553,642. Filed Aug. 20, 1894.
Registers the wheels of a train as it passes into a block.

AUTOMATIC REPEATING RAILROAD SIGNAL. R. H. Innes, San Antonio, Tex., 553,733. Filed March 30, 1895.

Dynamos and Motors:—

ARMATURE FOR ELECTRIC MACHINES. R. M. Gardner, Chicago, Ill., 553,557. Filed May 27, 1895.
The purpose of the invention is to avoid possibility of the breaking of the wires which connect the commutator-segments with the armature coils.

CONTROL SYSTEM FOR ELECTRIC MOTORS. G. Sautter, Paris, J. M. H. Savatier and C. E. De Lagabbe, La Seyne, France, 553,819. Filed Sept. 21, 1893.
This invention relates to means for electrically maneuvering armored turrets, guns and ammunition on board ships and in fortified places.

Electrometallurgy:—

ELECTROLYTIC BATH AND APPLIANCE. J. H. George, New York, 553,732. Filed May 8, 1895.
As a new article of manufacture, a sectional bath for holding a solution composed of a homogeneous, flexible and insulated material, provided with a concaved web, and sufficiently rigid to hold the containing solution.

PROCESS OF AND APPARATUS FOR EXTRACTING GOLD FROM ITS ORES. L. Pelatan, Paris, France, and F. Clerici, Milan, Italy, 553,816. Filed June 25, 1895.
Combination of the cyanide and electric process.

Galvanic Batteries:

ELECTRIC BATTERY. J. W. T. Olan, New York, 553,719. Filed Aug. 5, 1892.
The combination with an electric battery, of a source of supply of consumable material therefor, an electromagnet governing said supply, an instrument responding to variations of tension located in multiple arc to the battery circuit, and a circuit breaker for the electromagnet actuated by said instrument, said circuit breaker having adjustable liquid terminals whereby the tension of the battery circuit will be automatically maintained.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. J. Bagnall and G. Arnold, Cleveland, O., 556,637. Filed Oct. 2, 1895.
Provides means whereby to prevent the repeated separations of the carbons, rupturing of the arc, and consequent violent chattering in an alternating current arc lamp.

INCANDESCENT LAMP. H. Green, Hartford, Conn., 553,673. Filed April 16, 1895.
An anchored bent loop filament.

ELECTRIC ARC LAMP. H. O. Swoboda, New York, and E. Lavens, Brooklyn, N. Y., 553,697. Filed Sept. 6, 1894.

Miscellaneous:—

AUTOMATIC COAL RECORDING SYSTEM FOR RAILWAYS. F. A. Walters, Denver, Colo., 553,632. Filed May 23, 1895.
A storage and recording system comprising the receptacle chutes or storage devices of determinate capacity, means for discharging the same, time recording mechanism, etc.

DENTAL LIGHT AND HEATER. F. H. Stafford, Chicago, Ill., 553,572. Filed May 27, 1895.

MANUFACTURE OF VANILLIN. M. Otto and A. Verley, Courbevoie, France, 553,593. Filed July 3, 1895.
The manufacture of vanillin by subjecting a solution of isoeugenate of soda or other base to electrolysis and then treating by means of an acid.

COMBINED FEED-WATER HEATER AND PURIFIER. J. E. Smith, Chicago, Ill., 553,694. Filed June 24, 1895.
A construction wherein is created a galvanic action, to which the feed-water of the boiler is subjected.

Railways and Appliances:—

METHOD OF ELECTRICAL PROPULSION FOR STREET OR OTHER CARS. J. Jackson, Clinton, Ia., 553,529. Filed Nov. 10, 1893.
Details relating to a trolley conduit with insulated main conductors.

ELECTRIC RAILWAY CONDUIT. A. Beck, Atlanta, Ga., 553,552. Filed Nov. 2, 1894.
Details of construction.

UNDERGROUND TROLLEY SYSTEM. N. H. Anspach, Chicago, Ill., 553,635. Filed Aug. 20, 1895.
A conduit structure formed by specially constructed slot rails along the center of a surface track.

ELECTRIC RAILWAY SYSTEM. J. F. Page, Chewacla, Ala., 553,736. Filed June 28, 1895.
In an electric railway, in combination with a series of movable contact plates located along the track and adapted when moved to be connected to the main feed-wire, a motor car having an endless cable connected in circuit with its motor, and adapted to contact with and move said contact plates.

ELECTRIC RAILWAY. M. L. Wood, United States Navy, 553,799. Filed Sept. 12, 1895.
Details relating to a conduit railway.

Switches, Cut-Outs, Etc:—

LIGHTNING ARRESTER. E. G. W. C. Hoffmann, Charlottenburg, Germany, 553,528. Filed Sept. 3, 1895.
A solenoid magnet interposed in circuit with two arrester devices and controlling the arc of the primary arrester device. The secondary arrester has a fusible body interposed between its opposing plates to facilitate the passage of the electrical discharge.

RHEOSTAT. W. H. Morgan, Alliance, O., 553,538. Filed Nov. 21, 1891.
Consists in a base, a resistance medium carried thereby, plates partly embedded in said resistance medium, and a movable contact carried by the base and adapted to engage the plates.

ELECTRIC SWITCH. J. C. Fagan, Watertown, N. Y., 553,730. Filed May 6, 1895.
The object is to provide a simple combined switch and cut-out having the fuses separately covered with refractory material.

Telegraphs:—

TELEGRAPH REPEATER. B. F. Merritt, Newark, N. J., 553,535. Filed May 20, 1895.
In a telegraph repeater, the combination with a pair of polarized relays, of an automatic locking relay having a pair of vibrating levers adapted to move one in the path of the other, a pair of batteries and connections, means carried by said levers to short-circuit the batteries, and contacts for the levers of the polarized relays in said connections.

ELECTROMAGNET. C. D. Haskins, Brooklyn, N. Y., 553,675. Filed May 18, 1889.
An electromagnet with two insulated conductors in concentric sections or helices, each conductor including an inner and outer section or helix. Designed for duplex and quadruplex relays.

Telephones:—

COMPOSITE TELEGRAPHIC AND TELEPHONIC TRANSMISSION. E. E. Backus, New York, 553,605. Filed June 17, 1895.
A telegraphic circuit main line constituting one conductor of a double wire telephone circuit, with a double wire relay, and an induction coil, one winding of both being serially included in the main circuit, and the other winding of the said relay and induction coil being joined up serially in a short closed circuit.

ANTISEPTIC DIAPHRAGM FOR TELEPHONES. E. Weschke, San Francisco, Cal., 553,633. Filed May 9, 1895.
A diaphragm composed of a fabric capable of absorbing an antiseptic, cut into disks of suitable size to fit over the mouthpiece.

REPORTS OF COMPANIES.

STANDARD UNDERGROUND CABLE CO.

The annual meeting of the stockholders of the Standard Underground Cable Company was held at the company's office, Pittsburg, January 28, 1896. Nearly seven-eights of the capital stock of $1,000,000 was represented, either in person or by proxy.

The following gentlemen, all of Pittsburg, were re-elected as directors for the ensuing year, namely, George Westinghouse Jr., president of the Westinghouse Air Brake Company and the Westinghouse Electrical and Manufacturing Company; Robert Pitcairn, Mark W. Watson, J. W. Dalzell, George B. Hill, John B. Jackson, James H. Willock, John Morehead, Jr., and Joseph W. Marsh, the vice president and general manager of the company.

The report of the board of directors showed a total business of nearly $1,000,000 for the year 1895. During the year three quarterly dividends of 1½ per cent. each and one of 2 per cent. were declared, and the remainder of the earnings were carried into surplus account, which now stands at $446,869, notwithstanding the fact that at the beginning of the year 1895 $100,000 was charged off on patent account and $47,000 on account of bad debts, doubtful assets, etc., arising in the first twelve years of the company's existence.

Early in the year 1895 a large two-story and basement building (factory C) was completed and occupied, adjacent to the company's other factories, at the corner of Sixteenth street and Allegheny Valley Railroad, in the heart of the manufacturing district of Pittsburg, and factory B was remodeled into a three-story and basement building, 55x117 feet, of first-class slow-burning construction. The original factory, A, is a large four-story and basement building, and all three factories were equipped during the year with automatic sprinklers, thus greatly reducing insurance premiums, and making a serious fire practically impossible, and so obviating any danger of inability to fill orders on account of fire—an extremely important consideration—where, as in the case of this company, the orders have kept the factory running night and day throughout most of the year.

A large quantity of additional machinery was bought or built and erected in the company's factories during the year, the most important part of which is a moderate-sized but complete modern plant for the manufacture of rubber-covered wires and cables, so that this enterprising company is now prepared to furnish wires and cables of any kind a customer may desire, whether insulated with fiber, paper or rubber. All these improvements, costing between fifty and sixty thousand dollars, were paid for out of the current funds, without contracting any debt whatever on account thereof.

The company carried over into January a large amount of unfilled orders, and the orders booked so far in January have been spread over a wide extent of territory, and the prospects for a large business in 1896 are considered very good.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

AN ALTERNATING ARC LAMP.

The General Incandescent Arc Light Company have recently brought out a lamp for alternating currents, which is so up-to-date in every respect that it may well nigh be considered perfect. It is a reflector-plate focusing lamp, keeping the arc in one spot and reflecting the light down. Simplicity, strength and economy are some of its characteristics. It is made in seven different styles, plain or ornamental, wrought iron or polished brass, thus assuring its attractiveness to people of various tastes. The accompanying illustration gives an idea of its general appearance.

Mr. R. B. Corey, 714 Havemeyer Building, New York, is general sales agent for the above company and is thoroughly prepared to supply lamps for every variety of use, as well as the Sun Schmelzer Nurnberg Carbons. He reports the demand for the latter as being unusually large for this time of the year.

PRIOR CLAIMANTS FOR CATHODOGRAPHY.

Note has already been made in these pages of the claims put forward by more than one investigator, to have preceded Professor Roentgen in the discovery of the art of photographing by cathodic or X-rays and of producing "cathodographs." Another claimant, who has more to base his claim on, is Mr. Hans Schmidt in Munich, who sent in for publication last year in "The Photographic Review," a paper which has only just appeared, wherein he maintains that objects and materials which seem impenetrable to light rays are nevertheless not so. He says that the ultra-violet rays in electric light, which do not produce the effect of light on our eyes, pierce through blackened paper, thin wood, India rubber and other materials, while thin layers of metal keep them back. These discoveries in and about the field where Professor Roentgen works will not harm the latter's well-earned fame.

CAMPBELL-ZELL COMPANY'S BOILER CONTRACT.

The Campbell-Zell Company has just secured the contract for the boilers for the Maryland and Columbia railway, the new electric road between Baltimore and Washington. There will be two power-houses, one at Ilchester and another at Hyattsville, each to contain 3,000-horse-power boilers of the Zell improved water-tube safety boilers. The competition for this order was very lively, and the "Zell" was selected only after a careful examination of the points of merit presented. The examination was conducted by experts employed for this purpose.

CHOICE BUFFALO LAND FOR SALE.

Mr. Charles H. Phelps, formerly associated with the old electrical concern of W. H. Gordon & Co., now has an office at 71 Broadway, where he is handling and offering for sale some very desirable Buffalo real estate in what is known as the Kenmore District, between Elmwood and Delaware avenues, and within touch of three trolley lines, one of which runs to Niagara Falls. Tonawanda is close by, and the land lies in the region where Buffalo expects to do her best growing during the next twenty-five years. At present the prices of real estate there are low, in spite of incipient booms, and Mr. Phelps will be glad to see or call on any old electrical friends in order to give them a chance to "get in on the ground floor."

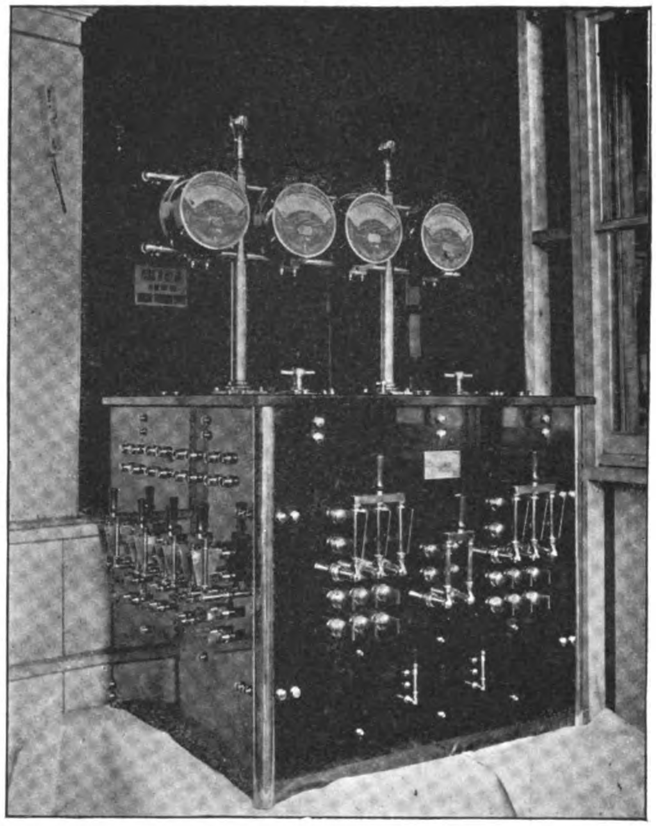
PHILADELPHIA NOTES.

The Apollo Iron and Steel Company, Apollo, Pa., have ordered for their new works at Vandergrift, Pa., three 400 H. P. medium speed "Ball" automatic cut-off side crank engines, direct-connected to Westinghouse generators. The engines are the first of a new line of side crank medium speed engines being brought out by the Ball Engine Company, Erie, Pa., which are especially adapted for direct connection.

THE WARNER SWITCH BOARD.

The accompanying engraving illustrates a new and novel design in switchboard work. It was built by the Electric Engineering and Supply Company of Syracuse for Charles H. Warner, consulting electrical engineer of No. 50 Broadway, New York, and sold through their New York representative, Mr. F. M. Hawkins, of No. 27 Thames street.

The switch board is made of polished black slate, in the form of a cube 3 feet 6 inches by 3 feet 6 inches. The dynamo



THE WARNER SWITCHBOARD.

switches with a capacity of 250 amperes each, are mounted on the front panel and the circuit switches on either side. The bus-bars and all connections are made on the back and inside of the cube, and the dynamo and circuit wires are brought up through the floor inside of the cube.

The top slab carries the rheostat dials and voltmeter switch, as well as the polished brass columns supporting the instruments. The instruments are of the Weston round pattern type and connections to the shunts are brought up through the brass columns, which are made hollow; the wires connecting the pilot lamps on the top of columns are brought up in the same manner.

The edges of the cube are covered by a nicely-polished and lacquered brass moulding.

Access to the interior of the board is had through brass-grilled doors at the rear. The board is placed in the center of a handsome engine-room and presents a remarkably rich and attractive appearance.

A LAMP VALENTINE.

The manufacturers of the Packard lamp recently received from one of their customers an interesting souvenir in the shape of an old, burned-out Packard lamp, together with a valentine card, on which was written: "This lamp has been in constant use for two years and three months." Accompanying the valentine was the following letter:

"Gentlemen—I herewith send you a valentine souvenir which would be a curiosity if placed in your new catalogue. Trusting you may appreciate this little memento and keep it for future reference, we are, very respectfully yours,

"THE CINCINNATI GAS LIGHT AND COKE CO.,
"Electrical Department.
"C. F. Hesser, Vice-President and General Manager."

The Electric Appliance Company has had the souvenir on exhibition at 242 Madison street, where it has attracted considerable attention. A lamp which has burned over 18,000

hours is certainly entitled to more than ordinary respect, even if it does not retain its original efficiency and economy.

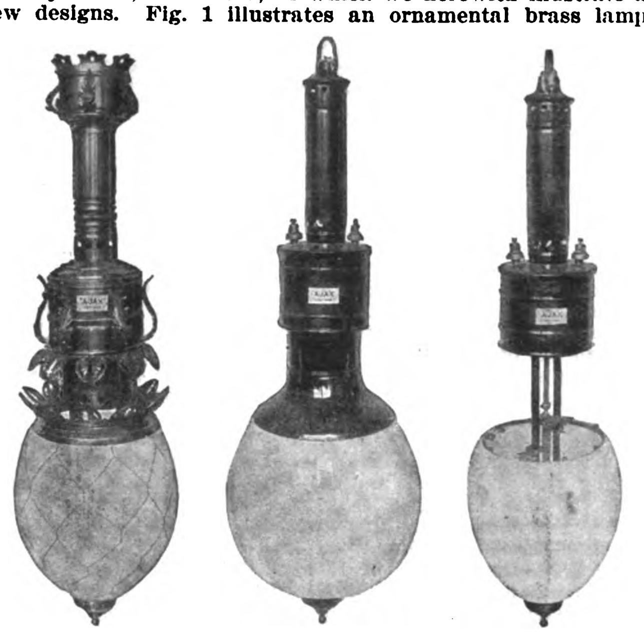
THE SHELDON LABORATORY.

Dr. Samuel Sheldon, of the Brooklyn Polytechnic, announces in our columns this week that he has established a laboratory for special tests, research, etc., where work of such character will be undertaken for public and private clients. The institution is one that we can cordially recommend for patronage to our readers. Dr. Sheldon is a graduate of Middleburg College, where in 1883 he took the highest honors in physics. He was instructor in mathematics there for two years. He then went to Würzburg University (where Prof. Rontgen is now doing his remarkable work in photography with the cathode rays), and was there for three years, acting during two years as assistant to Prof. Kohlrausch. On his return to this country he became assistant to Prof. Trowbridge at Harvard. In the fall of 1889 he was called to the Brooklyn Polytechnic, where he has been ever since as Professor of Physics and Electrical Engineering.

Dr. Sheldon has done wisely in equipping his laboratory with a set of certified copies of the celebrated Reichsanstalt standards, including large compensation apparatus, standard photometer with Heffner-Alteneck lamp, Thomson double bridge for conductivities, small resistances for heavy currents and all sized resistances with Reichsanstalt certificates. He has, of course, also voltmeters, ammeters, etc., of all sizes and kinds in all the standard makes, no expense having been spared to render the equipments for each class of work the most perfect and complete obtainable. Dr. Sheldon is already known as a careful and successful investigator, and it is fortunate that in view of the rapid development of electricity and the allied arts, opportunities for test are rendered so immediately available.

THE VAN NUIS ARC LAMP.

One of the recent additions to the already long list of arc lamps is the "Ajax," manufactured by C. S. Van Nuis, of 136 Liberty street, New York, of which we herewith illustrate a few designs. Fig. 1 illustrates an ornamental brass lamp



FIGS. 1, 2 AND 3.—VAN NUIS ARC LAMPS.

with opal globe and rich cast-brass corona. Fig. 2 illustrates a black japanned case, with round globe and spark arrester, as arranged for outdoor use, the resistance coils being mounted upon porcelain insulators on a detachable frame within the tube at the top of the lamp, making the lamp complete in itself and presenting a compact and neat appearance. Fig. 3 illustrates practically the same lamp as Fig. 2, with the spark arrester removed, showing the type of globe-holder adopted for use with these lamps, which is only one of the many little ingenious devices that enter into the make-up of the Ajax lamp, contributing toward a serviceable and artistic whole.

The regulation is accomplished by a single magnet, which attracts an armature through a long arc and controls at the further end of a rock-shaft a triple movement, which acts upon the rack or upper carbon rod. This triple movement is accomplished in a very ingenious manner by a simply constructed frame and brake-wheel, which, we are told, will admit of the lamp striking approximately a normal arc, and maintaining a uniform candle power throughout the life of the carbons. So far as the simplifying of the controlling movement to a single unit is concerned, the designer of the Ajax lamp has reached that goal; but he has deemed it advisable to introduce the more sensitive triple movement into the feed mechanism, in order to insure a more gradual and delicate adjustment of the arc than could be obtained by applying a simple magnet movement direct.

It is claimed for the "Ajax" lamp that a considerable variation in the governing magnet, due to a sudden rise or fall of potential of the circuit, supplying the lamps, will affect the arc but slightly, because such sudden variation is largely compensated for by the three-fold movement above described. It would appear, therefore, that with a closely regulated circuit the "Ajax" lamp would feed by inappreciable increments, giving an absolutely steady light, and that with an ever-varying potential these fluctuations would be minimized at the arc.

ADVERTISERS' HINTS.

BRUNT AND THOMPSON, East Liverpool, Ohio, are introducing a cleat, which they assert is the most perfect ever manufactured.

THE STANDARD AIR BRAKE COMPANY show a Brill car in one of their "ads" in this number. This car and 180 more on the same road are equipped with their braking apparatus. It is the object of this company to make the use of the "Standard" brake on electric cars as universal as that of the Westinghouse brake on steam cars, and, judging by the present rate of their adoption, it would seem this is not only reasonable, but certain.

THE HESS STORAGE BATTERY COMPANY, Philadelphia, Pa., have some things to say about their double electrode battery, and call attention to the results of a test by Messrs. Houston and Kennelly, proving its efficiency to be of the highest. Send for their interesting catalogue.

THE POPE MANUFACTURING COMPANY is now the Chicago representative of the Calculagraph Co.

THE INDIA RUBBER AND GUTTA PERCHA COMPANY invite any users of their wires and cables to prove they are not what they claim them to be.

THE WESTINGHOUSE MACHINE COMPANY present some very interesting information regarding the selection of materials in building their engines. It is quite sufficient to convince the mose skeptical of the great care taken to produce an engine of the highest grade.

SEVEN MILLION EDISON SOCKETS AND RECEPTACLES are in daily use in the United States. They are manufactured in every conceivable variety by the General Electric Company.

ANOTHER ELECTRIC RAILWAY COMPANY is attesting to the efficiency of the Lombard waterwheel governors.

NINETEEN THOUSAND HOURS OF LIFE is the record of a Packard incandescent lamp. The Electric Appliance Company state that lamps of this make are just as "long" on candle power as they are on life.

"MICANITE" is the insulation used on more than 600 motors of the street railway system of Lynn, Mass.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY illustrate several styles of the "I-T-E" automatic magnetic circuit breakers. They are of various designs, especially adapted to the many kinds of service.

BLADE KNIFE SWITCHES are advertised by the Emerson Electric Manufacturing Company. Their latest catalogue and discounts will be mailed on request.

BOWERS BROS., of Chicago, are well qualified to supply anything in the insulating line. Mica is their specialty.

EIMER & AMEND, of New York, are having a lively demand for Roentgen tubes, suitable for photographing invisible objects, a new departure in science which is at present attracting the attention of the whole scientific world. Eimer & Amend are particularly well equipped for this class of work, and maintain a glass-blowing department, so that any desired shape of tube can readily be made to suit the experimenter. They carry also a large stock of induction coils, and the necessary fluorescent salts, and are thus capable of fitting out any laboratory for making these extremely interesting experiments.

THE AUTOMATIC CIRCUIT BREAKER CO., of Newaygo, Mich., reports that its business was double during the month of January that in any month since it started, which ought to demonstrate that its instruments are coming to the front very rapidly. It has never as yet had one of its instruments returned when sent out on approval.

Department News Items wil be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. FEBRUARY 12, 1896. No. 406.

POWER TRANSMISSION.

WESTINGHOUSE TWO-PHASE POWER PLANT IN THE MILWAUKEE HARVESTER CO'S WORKS.

WHILE electricity has not as yet been applied to agriculture to any great extent, it has recently come one step nearer that field by the installment of a two-phase power transmission plant in the works of the Milwaukee Harvester Company, at Milwaukee, Wis.; and the farmer, as he rides his harvester or mower, may now feel that, while this wonderful agent is not yet directly available for his use, he is at least in close touch with it, and that it has been instrumental in producing cheap machinery for his use.

The Milwaukee Harvester Company started in the Fall of 1881 with 125 men in its employ and an output of 1,200 harvesters and 500 mowers. The business has had a remarkable growth, until at the present time they employ 600 men, and are shipping 12,000 harvesters and 10,000 mowers a year. An idea of the extent of the business may be obtained from the fact that they use 5,000,000 feet of lumber a year, and during the harvesting season ship fifteen carloads of complete machinery a day.

The plant which produces this large output comprises twenty buildings, ranging from one to five stories in height, most of them being of brick, and the whole covering an area of about ten acres. While the management of this company have accomplished much toward reducing the cost of manufacture and increasing the output by strict business organization and putting in operation the piece work system of

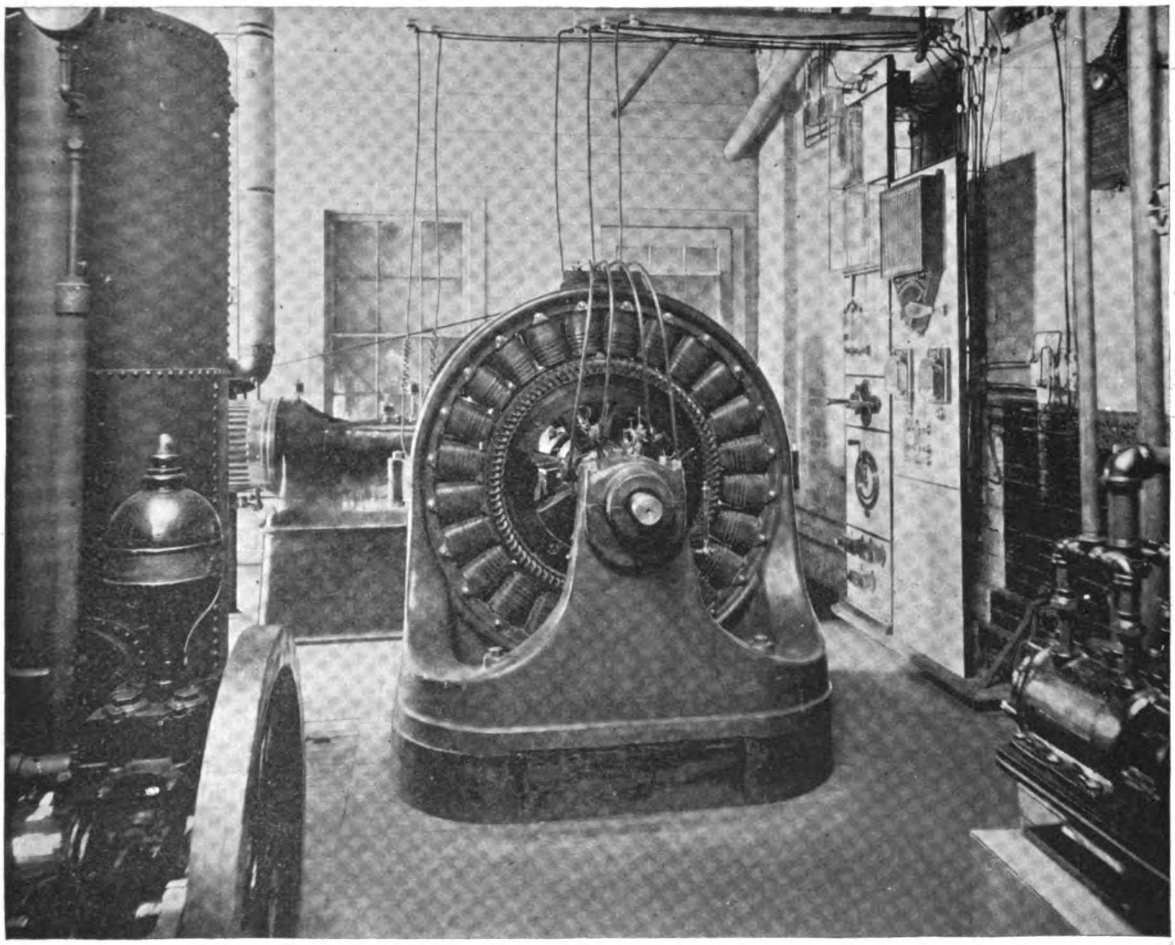


FIG. 1.—WESTINGHOUSE TWO-PHASE POWER PLANT, DRIVEN BY BALL & WOOD ENGINE, IN THE MILWAUKEE HARVESTER WORKS.

labor, and labor-saving machinery, they have realized for some time that they must soon look for some new way of further accomplishing their object—viz., increasing earning power. While they had their men working to the best advantage, while they had the best machinery, good buildings and plenty of power, their method of getting their power to the machines and men was the old one of shafting and belts. They found that as the load on these shafts and belts varied

during the day, their speed, owing to slip, varied greatly, especially at remote points.

With improvement in view, the Manager, Mr. G. H. Schulte, called in Mr. G. G. Armstrong as consulting engineer. After thoroughly canvassing the situation, they decided to put in a complete system of electrical distribution of power, and do away with their old sys-

FIG. 2.—CEILING MOTOR IN OIL AND PAINT HOUSE.

tem of long shafts and belts. After thorough consideration, the polyphase system of the Westinghouse Electric and Manufacturing Company was thought to meet the existing conditions most satisfactorily.

As a sort of preliminary plant, which could be made use of immediately in helping out the old system, and at the same time furnish a good trial as to the reliability and efficiency of the electrical system, it was decided to install a 75-kilowatt generator and use it during the present season, putting in motors wherever they could be made the best use of. Later, if satisfied, they planned to build a new power house and put in a complete system of electrical transmission. The

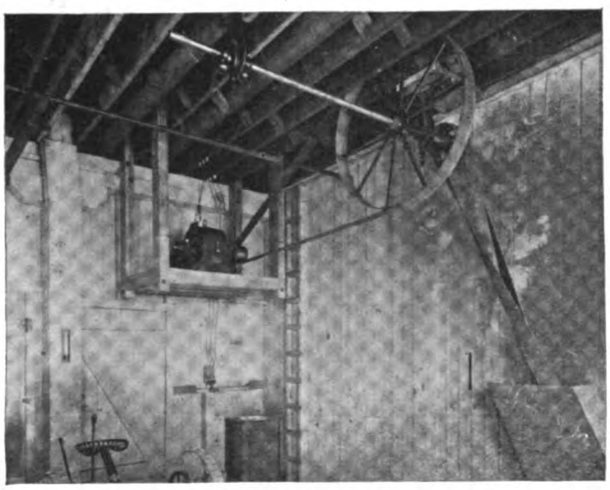

FIG. 3.—MOTOR IN HARVESTER TESTING ROOM.

generating plant illustrated in the engraving, Fig. 1, at present comprises a 75-kilowatt two-phase generator of 7,200 alternations and 440 volts, directly connected to a 125-horse power Ball & Wood engine, running at 300 revolutions per minute. The switchboard and intruments are of the regular Westinghouse type. While the plant is primarily for power work, it is also made use of for furnishing about 220 incandescent lights.

The motors are of various sizes, and are all of the latest non-synchronous type, built by the Westinghouse Company. Wherever they are located in a room where work is being done on the floor, they are suspended from the ceiling by substantial wooden hangers. This not only insures a dry, clean place for the motors, with no danger of anything falling into them, but at the same time has the advantage of taking up no valuable space.

Fig. 2 shows a 10-horse power motor, located in the oil house and used for driving paint grinders and mixers. On account of fire risks this building is located some eighty feet from any other building, and an 80-foot shaft was previously used for conveying the power. This motor carries steadily an overload of 25 per cent., without heating dangerously.

Fig. 3 shows a 5-horse power motor, used in driving the harvester testing room. This motor took the place of 75 feet of shafting, three pulleys and two belts. The saving of power in this case is very evident.

Fig. 4 shows a 20-horse power motor driving the shaft in the mower bar room, and also an elevator, not

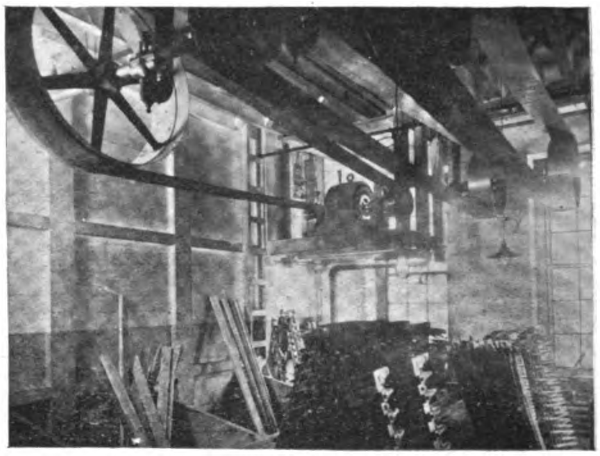

FIG. 4.—20 H. P. MOTOR RUNNING ELEVATOR AND SHAFTING.

shown in the cut. This motor gets rid of 60 feet of shafting. The power used was formerly transmitted through 340 feet of shafting and belting from the engine. A 50-horse power motor is also used, belted to a No. 7 Sturtevant fan, furnishing a blast to two cupolas of thirty tons capacity per day. This fan was formerly driven by a shaft 200 feet long; and the power transmitted through several shops from the engine 520 feet away. The result was that, as the load on the shop varied, the speed of the fan changed, thus giving an irregular blast to the cupolas and badly interfering with the results. With the motor, the speed remains practically constant, and it is found that the same amount of iron can be melted and poured in about one half hour less time than formerly. The importance of this is realized when we consider that this means one-half hour for 125 men, or 62.5 working hours every day; or 18,750 hours per year of 300 days. Taking the average price of labor at twenty cents per hour, this is $3,750 worth more of labor with the same men and the same foundry; while at the same time the product is of a much better quality, due to the iron always being at the proper temperature.

There are several other motors running elevators, shafting, etc., not shown in the cuts. One of these, of

7½-horse power, took the place of 200 feet of shafting and is 520 feet from the engine. The whole plant has been running since being started, some months ago, without an accident of any kind, and is giving great satisfaction.

One great convenience connected with the plant is the ease with which the engineer shuts down and starts up the plant. In shutting down, all switches are left in; in fact, the entire plant is in the same condition as when running. In starting up, the generator is excited and the engine started. This gives a current at low voltage and alternations. The motors immediately start with whatever load is on them, and come right up to speed along with the engine. Thus one man starts and stops the whole plant without any help or any time being lost in going around and starting separate motors, as would be necessary in a direct current system. It will be noted that no use is made of the starting resistances, except when starting a motor with full voltage and alternations on the line, as the motors have a strong starting torque at so low a periodicity.

The management of the company have decided to build a new power house in the Spring, and equip it with high-grade machinery, both steam and electrical. The new building will be of brick 60x120 feet, and located in the centre of the grounds. From this centre, all power will be distributed to motors located in the various departments. This change will be looked forward to with interest, as it is the intention to make it in all respects a model two-phase power plant.

ON THE SUSQUEHANNA.

The Susquehanna Electrical Company has purchased a large island in the Susquehanna River, opposite Peach Bottom, and the Peach Bottom Ferry privileges. The ferry will probably be electrically operated. The company, besides acquiring much land on both sides of the river, has secured five miles of Muddy Creek, from which 2,500-horse power will be derived and used to generate electricity to light Delta and operate the slate quarries.

POWER INCREASE OF THE NIAGARA FALLS PAPER CO.

So successful has been the experience of the Niagara Falls Paper Company in the use of tunnel power that they are about to double their already large plant on the lands of the Niagara Falls Power Company. This paper mill started operations in February, 1894. They have been using 3,000 h. p., while their wheel pit, which is connected with the main tunnel by a lateral, has a capacity of about 8,000 h. p. They will install new turbines to give them 3,000 h. p. additional. This company were the first users of tunnel power, having purchased it undeveloped and excavated their own wheel-pit and lateral connection. The turbines used by them are known as the Geyelin improved inverted Jonval turbines, the product of R. D. Wood & Co., of Philadelphia, Pa., who will make the new wheels.

This latest step on the part of the paper company is one of the most notable that has occurred recently at Niagara, for it means a big increase of an already extensive paper-making plant. The improvements contemplated include a new boiler house, in which 750 h. p. additional will be made available; a new pulp mill with ten more grinders, or an increased capacity of forty tons per day; a new sulphite plant of thirty tons additional capacity, besides other buildings for various purposes. But the company have also been buying up more spruce timber land, and now they hold title to no less than 239,000 acres of the best on the continent. In order that this may quickly and readily be laid down at their mill, they will put in new vessels, so that almost each day will see a vessel-load dispatched to them.

The present buildings of the company do not occupy all the land at their disposal, so that there is ample room for the proposed new structures. Considerable of the machinery has been ordered, and the buildings will soon be commenced.

Naturally, the enlargement will afford work for many men. This departure is most substantial evidence of the great success of the Niagara power development by means of the tunnel. Not a single factory has yet located on the power company's lands but has displayed sufficient foresight to see that ample ground for extensions was available. The advisability and wisdom of this is seen in the present steps to enlarge the paper mill by doubling its capacity. Mr. John C. Morgan is the able manager of this mill, and his plant has been in constant operation since the day it started.

ELECTRIC POWER ON THE MAN OF WAR "BROOKLYN."

The "Brooklyn," following the recommendation of Captain Sampson, approved by the Secretary, will have electrical turning gear in half her turrets and steam gear in the others, in order to test the two by comparison.

The French turrets on the Canet electric system, recently illustrated in "The Electrical Engineer," are said to work very well, and they have besides safety gear a system of counter weights to provide for the automatic return of lever handles. In order, also, to provide for accidents, they are supplied with a supplementary hand gear. It is said that about forty Canet turrets worked by electricity have been turned out for different ships, or are now in progress, among the vessels supplied with them being the Chilian Capitan Prat and the Danish coast defender Skjold. The work has been perfected so that comparatively small powers are required for turning the turrets. England's Powerful and Terrible have electrically-worked barbette mounts for their 9.2-inch guns.

One stimulus to the introduction of electrical instead of hydraulic machinery for turret turning has been the liability of the latter to suffer in winter from the freezing of the water. This liability was illustrated recently in the case of one of our own second-class battleships. Russia, which is naturally interested very much in this matter, in relation to her Baltic fleet, has adopted the device of running steam pipes along the side of the hydraulic pipes, so that the water in the latter is prevented from freezing. Great Britain also took up this system, beginning with the Empress of India, and it may be adopted in our own ships.

THE NEW PHOTOGRAPHY.

(Professor Roentgen, of Würzburg, has discovered how to photograph through a person's body, giving a picture only of

O, Roentgen, then the news is true,
  And not a trick of idle rumor,
That bids us each beware of you,
  And of your grim and graveyard humor.

We do not want, like Dr. Swift,
  To take our flesh off and to pose in
Our bones, or show each little rift
  And joint for you to poke your nose in.

We only crave to contemplate
  Each other's usual full-dress photo;
Your worse than "altogether" state
  Of portraiture we bar in toto!

The fondest swain would scarcely prize
  A picture of his lady's framework;
To gaze on this with yearning eyes
  Would probably be voted tame work!

No, keep them for your epitaph,
  These tombstone souvenirs unpleasant;
Or go away and photograph
  Mahatmas, spooks, and Mrs. Besant.

—London "Punch."

THE ELECTRICIAN IN WARFARE.

At the last general meeting of the London Institution of Electrical Engineers, the president, Dr. John Hopkinson, F. R. S., referred to the recent international complications, and advised that electrical engineers should place their technical knowledge at the service of their country for the purpose of national defense. He said that their services would be invaluable in the matter of military telegraphs, submarine mining, electrical sighting of guns and searchlights. A committee was appointed to ascertain the number of engineers who were willing to enroll and to inquire as to methods in which their services could be utilized.

AN ELECTRIC COAT.

Major A. H. Swanson, of Texas, where they are supposed not to need such things, suggests that motormen can be kept warm in winter by hitching the trolley circuit on to their overcoats, which have a resistant network of wire imbedded in them, and thus warm up. This is something like the idea that has been practically carried out in the "Electrotherm."

ELECTRIC LIGHTING.

DIELECTRIC STRENGTH OF OILS UNDER ALTERNATING POTENTIALS.

BY PROF. ELIHU THOMSON.

IN the course of tests made under the direction of the writer some two or three years ago, the interesting fact was noticed that the striking distances of high potentials in insulating oils were in some way variable with the frequency of the current or potential waves, or upon the time during which electric stresses existed in a given direction through the medium.

This relation has been confirmed by other and later experiments. The general effect was found to be that discharges at low frequencies are capable of puncturing mineral oil layers up to from one-third to one-half the thickness of an air layer required to just resist puncture by the same discharges, while with high frequencies of equal striking distance in air, an oil layer of one-thirtieth to one sixtieth of the thickness of the air layer was sufficient to prevent discharges. At frequencies such as 125 per second, a potential which would give one-half inch spark in air, may puncture from one-third to one-fourth inch of oil between the electrodes, while at frequencies of 50,000 to 100,000 a layer of oil of one-fourth inch may resist puncture when the spark in air is as much as eight inches. The high frequencies experimented with were such as are given by condenser discharges over an air gap, including a primary of a few turns, with a secondary of a single layer of some hundreds of turns immersed in oil. The discharges, in such cases, are not continuous waves, but a rapid succession of oscillatory discharges with dead intervals or periods of inactivity intervening.

The effect of carefully drying an oil was found to increase its insulating power. This was also true to a marked extent when careful filtering was resorted to, a decided decrease of striking distance through the oil with the lower frequencies being observed. It follows from this that all oil used in insulating for high potentials with low frequencies should be kept clean and homogeneous, and free from floating particles.

Variations of temperature of oil did not, in the experiments made, greatly affect the striking distances for a given potential. The general fact, however, that with high frequencies the insulating power of oil layers is, as measured by the striking distance in air relatively to that in the oil, far in excess of such insulating power for low frequencies, seems to be unaffected by the dryness, clearness or temperature of the oil used.

It appears probable, also, that with partially conducting liquids like alcohol and water the behavior with high frequencies is more like that of a true dielectric insulator than with low frequencies. As an interesting fact in this connection it may be noted that a high potential high frequency coil capable of yielding spark torrents over thirty inches of air gap between its terminals, still maintains its discharges even when shunted by a glass tube one and a half inches in diameter containing ordinary water, and long enough to bridge the gap.

It is difficult to account for the differences in the effects obtained with high frequencies from those with low frequency alternating waves. A time lag in the establishment of the full dielectric stress or full electrostatic field in the oil might account for the phenomena. According to this hypothesis if two electrodes under oil, separated a certain distance, instantly acquire a difference of potential this potential would not with equal rapidity strain the oil to the full extent. It might be assumed that the polarization of the oil molecules requires time; or, it may be that only such part of the electrostatic field as is due to the ether is first established after electrification and that the increase of such field, due to the molecules of the substance, such as the interposed oil, is subsequent to the former.

If this were so the establishment of an electrostatic field at high rates in oils would present analogies with the case of magnetic fields in iron or metals.

It would also follow, if the supposition of a lag as above be true, that in condensers such as those using oil as a dielectric, the capacity would be less the higher the frequency. Again, if any such lag as is assumed exists, it would probably vary with different insulating media, and it may depend upon the molecular state, as viscosity, for example. Observations of the oil space between the immersed electrodes by polarized light could probably be used with certain media to detect any differences in time of establishment of electrostatic stress with different frequencies, it being well known that under high stresses certain insulating liquids become strongly affected in their optical properties, with rotation of polarized beams of light traversing them. If the optical effect noticed should be less in the case of high frequencies than with low rates it would indicate a probable lag of the kind assumed. Similar studies using solid dielectrics like glass, mica, etc., would also be desirable. Should the results be negative it would be necessary to attack the problem in some other way.

M. P. Jaret, about a year or more ago, in a communication to the Paris Academy of Sciences, gave the results of his investigation of the properties of mica. He found that it did possess, with rapid oscillations, what might be termed a dielectric hysteresis. Such a property may exist to a more marked degree in oils.

In the tests of the power of oil layers to withstand puncturing by high potentials a curious effect was noticed, which was that discharges under oil passed far more readily between balls than between sharp points. In other words, with any given difference of potential between the immersed electrodes, as measured by the air spark obtainable, pointed electrodes could be brought much nearer than balls without provoking puncture. With balls of one-half inch diameter as terminals and with low frequency (125), potential differences, ranging from 100,000 to 150,000 volts, the space between the points could be one quarter that between the balls. The ratio between the length of spark in air and between sharp points in oil was 10 to 1 at 10,000 volts and 8 to 1 at 15,000, while with balls these ratios fell to 2.4 to 1 and 2 to 1, respectively. When flat plates were substituted for the balls the striking distance in oil was still further increased as compared with the distance with points. The seemingly anomalous action of points under oil, so different from their action in gases or air, is certainly curious, and the usual injunction to avoid points and edges as conducive to electric discharge does not seem to apply in such media as oil, at least when the potentials are alternating and at ordinary frequencies.

In experimenting with discharges in oil uniform results are only to be obtained by using carefully filtered oil, as ordinarily they contain suspended particles, fibers, etc., which appear to bridge the space between the electrodes and provoke a breakdown due to the

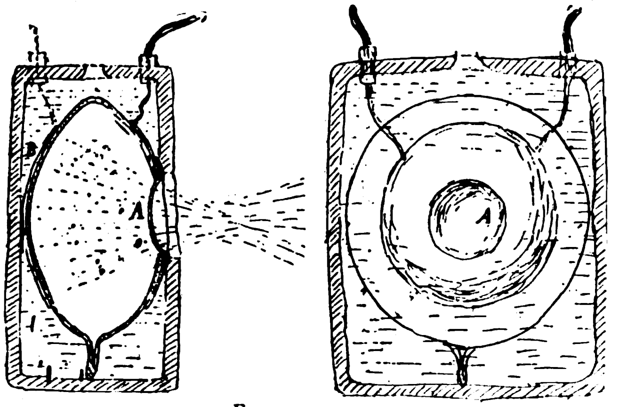
non-homogeneous character of the dielectric. It is also necessary to discard oil after arcing has once occurred through it, as it will have become much weaker owing doubtless to the fine carbon particles set free and which remain floating ready to be drawn into the space between the electrodes, thus giving rise to loss of homogeneity of the medium.

CATHODOGRAPHIC EXPERIMENTS.

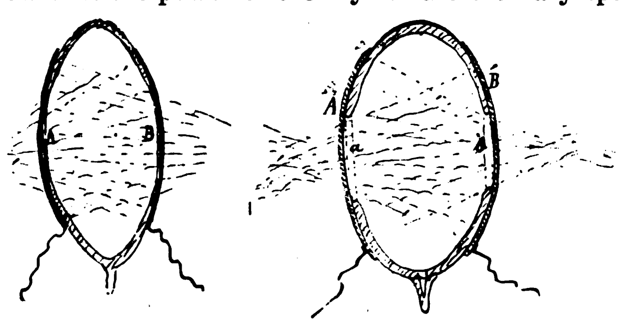
BY

Elihu Thomson

I WAS much pleased to find in your issue of Feb. 5 such complete accounts of cathode ray experiments and similar phenomena. It would certainly appear from what has been published that similar effects are possible to be obtained without the use of Crookes' tubes, but I may be pardoned for calling attention to the fact that we can hardly expect any activity in the solar rays, for the reason that such rays as reach us have passed a great depth of air the absorptive power of which, for cathode rays, would probably be quite sufficient to prevent their manifesting themselves at any point on the earth's surface, and, besides, to keep photographic plates as they are kept would be impossible. I am inclined to favor the hypothesis which has been attributed to Lenard, that the cathode rays are simply invisible rays far beyond the violet end of the spectrum—ether waves of very short wave length. We know that the power of the rays of the ordinary spectrum to affect silver salts is most marked at the upper end of the spectrum, and that such power is possessed by rays far beyond the visible spectrum. Violet rays have magnetic properties, as is well known, and cathode rays as they appear in the Crookes tube are deflected by a magnetic field. There is, then, apparently a relationship between magnetism and both ordinary violet light and cathode rays which with the cathode rays involve a displacement of the beam by magnetism, while with other waves of lower pitch, approaching the visible spectrum, such displacement might become infinitesimal, or too small to be measurable.



FIGS. 1 AND 2.



FIGS. 3 AND 4.

I may suggest, in this connection, an apparatus which ought to be capable of developing cathode rays of great power when excited by high frequency currents of high potential. It consists mainly of a glass vessel shown in section in Fig. 1, formed like a flattened sphere or oblate spheroid, and having an opening at A which is covered by a thin aluminum cap, as indicated, which is covered at the opening, A, and fits over the exterior of the glass vessel, being securely cemented thereto. This cap or aluminum cover is made as thin as possible consistent with proper strength to resist the pressure of the atmosphere. It forms not only a window for the escape of the cathode rays, but also a metallic conducting coating which is to be connected to one of the wires furnishing discharges for exciting the apparatus. The other coating is directly opposite and is seen at B, and is an exterior covering on the glass attached to the other terminal of the electric source. The concavity of B would be made such that the cathode rays leaving the same would be concentrated through the opening covered by A. The apparatus so prepared would be exhausted to the proper Crookes' vacuum and sealed.

In order that the excitation may be pushed without overheating; and in order, also, that the discharges should not traverse the cover of the bulb of glass, it would be advisable to immerse such a bulb in oil, particularly when it is subjected to the most vigorous excitation. To do this it would be only necessary to inclose it, as indicated in the sketches, in a box of hard rubber or wood filled with oil and having openings for the passage of the terminals, as far apart as possible. In order, also, to prevent the possibility of any oil layer obscuring the rays there would be a seal around the opening or window A, thus permitting the rays to pass freely into the atmosphere. A circulation of oil in case of heating would be easy to maintain and the apparatus could therefore be kept comparatively cool. Figs. 3 and 4 show evident modifications of such an apparatus. In Fig. 3 the glass should be made as thin as possible opposite the positions A and B, and then these portions are covered with aluminum caps cemented on and fitting as closely to the glass as possible. In this case the rays would emanate from both sides under high frequency excitation. In Fig. 4 the only difference in the structure would be that the glass would be cut away at A and B so as to give a double window, while the aluminum caps extending far from the openings are, as before, the electrodes. In this case the rays would emanate from both sides of the apparatus with equal facility under high frequency alternating currents.

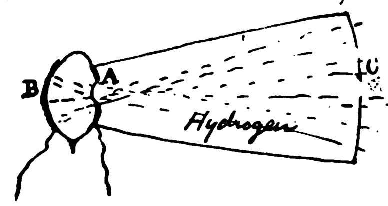


FIG. 5.

It would, of course, be possible to use perfectly spherical bulbs in such structures as Figs. 3 and 4, and this would conduce to cheapness of construction, as it would then only be necessary to prepare a bulb exhausted to a Crookes' vacuum, and use it entirely without internal electrodes, if desired. I have no doubt

that by carefully selecting incandescent lamps in accordance with the vacuum which they contain, and which is frequently a Crookes vacuum, they could be used as cathode ray generators by putting on two thin aluminum cups on opposite sides of the bulb which are made the terminals of a high frequency apparatus.

In order that the shadow pictures produced by cathode rays shall be as sharp and perfectly defined as possible, the rays themselves should emanate from a spot some distance away from the object, the shadow of which is to be cast upon the sensitive plate, and the further away the better, but, of course, the rays become less effective at the increased distance, as do rays of light, and they are also absorbed by the air layer and thus undergo a further diminution of activity. Lenard found that the cathode rays passed through a vacuous chamber quite freely, and that they were conveyed with less loss through hydrogen than through air. It would, therefore, seem that the cathode ray generator could most effectively work at a distance by interposing a tube or cylinder containing hydrogen gas, or, in other cases, a vacuum chamber; if the ray generator is to be placed at any considerable distance from the objects. This is illustrated in Fig. 5, where A B is the cathode ray generator inclosing a Crookes vacuum, and from A to C is the chamber filled with hydrogen gas, while the object the shadow of which is to be thrown upon the sensitive plate would be placed beyond C, and, lastly, the plate beyond the object itself.

The above suggestions are made for the purpose of assisting experimentation in this field on the part of those who will undoubtedly take up the work, and with the object of utilizing large amounts of energy in the production of cathode rays.

I might add that I made some experiments which have succeeded in yielding a picture of a number of coins, or rather coin shadows, on the sensitive plate. The coins were separated from the plate by a single thickness of black paper, and above the coins two thicknesses of heavy pasteboard, perfectly opaque to ordinary light, existed. The Crookes' tube was supported about 4 inches above the pasteboard, and excited by one of my higher frequency coils adjusted to a spark of about two inches or more. The exposure or excitation of the Crookes' tube lasted about seven or eight minutes, resulting in the production of a negative quite dense enough to print from.

KILLED WHILE STEALING LIVE WIRE.

While stealing fully-charged electric light wires in Newark last week, a man named J. B. Gove received a shock while on a pole twenty-five feet above the sidewalk and fell. His skull was fractured and he died instantly. A companion engaged with him in the thefts disappeared. His identity is unknown.

The two men were thoroughly equipped as linemen, and early in the night stopped with a horse and wagon, which contained a ladder, some tools and a quantity of wire, in front of No. 298 Belleville avenue. They took the ladder to a pole and Gove ascended.

He had cut one strand and was working on another when he gave a cry, threw up his hands and fell head foremost, landing on the block pavement. The other man ran to him, seemed to realize that he was dead, took Gove's watch from his pocket, jumped into the wagon, lashed the horse and drove away before the astonished onlookers could interfere.

A physician and policeman were summoned, and an examination showed that Gove's left hand had been badly burned by the wire. His skull was fractured and his legs and other bones in his body were broken. It was learned that Gove formerly worked as a lineman in Atlantic City.

JACKSONVILLE FLA.—Adams & Richardson are now doing their refrigeration by electricity, a twelve-horse power motor having been recently installed in their place by Johnson Law.

MR. EDISON'S EXPERIMENTS WITH X-RAYS.

It is safe to say that there is probably no one possessed of a vacuum tube and an induction coil, who has not undertaken to repeat Professor Roentgen's experiments in obtaining shadow photographs, or cathodographs, as they have been called, while those who

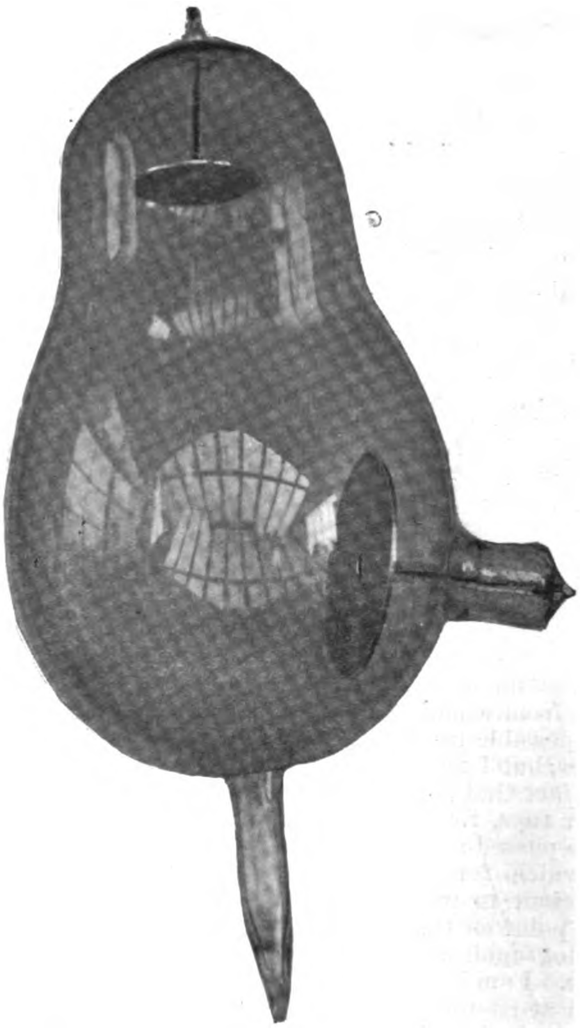

FIG. 1.—VACUUM BULB MADE FROM INCANDESCENT LAMP; USED BY MR. EDISON FOR OBTAINING THE RÖNTGEN EFFECTS.—FULL SIZE.

are fortunate enough to possess larger facilities for experimentation have taken up the work enthusiastically. Among the latter is Mr. Edison, who, with his characteristic energy, and fertility of invention, has already placed at the disposal of future experimenters some facts which cannot fail to be of value in the prosecution of research in this direction.

Before proceeding further it may be well to state that Mr. Edison considers the X-rays more in the light of static thrusts than of undulatory propagations, and that their effects on the sensitive photographic film are due rather to direct mechanical than to chemical action. He cites as an analogy the power of a tuning fork, of certain pitch, to detonate iodide of nitrogen when brought near the latter.

Regarding the construction of the tubes for producing the X-rays Mr. Edison differs from many experimenters in this field, who hold that a high vacuum is necessary to obtain the effects. In proof of his contention Mr. Edison has made quite a large number of experiments, which go to prove that the vacuum

required is largely dependent upon the potential available; thus, in his own experiments, in which he has employed a coil giving a 4-inch spark, he finds that the best point at which to seal off the lamp from the pump is that at which all glow within the interior of the lamp ceases, and fluorescence of the glass alone is observed.

The vacuum tube employed by Mr. Edison, which is illustrated in Fig. 1, is made from the bulb of an ordinary 16-c. p. lamp, into the top of which is fused a platinum wire, carrying a disk $\frac{3}{4}$ of an inch in diameter, made of polished aluminum. At the side of the lamp bulb there is fused in the cathode terminal, consisting of a disk $1\frac{1}{4}$ inches in diameter, also made of polished aluminum, but placed at right angles to the upper disk. The object of this arrangement, of course, is to allow the cathode rays to be thrown off and to act upon interposed objects, without interference from the anode terminal. By employing an incandescent lamp bulb, the thickness of which is only 1/64 of an inch, Mr. Edison finds that the interference due to the intervening glass is very small, as compared with that of the Crookes tubes, which are in general use.

Mr. Edison, as will be seen, employs anode disks, instead of the simple platinum wire terminals, for the reason that the disk keeps cool, even under continuous use of the vacuum bulb, whereas the platinum wire

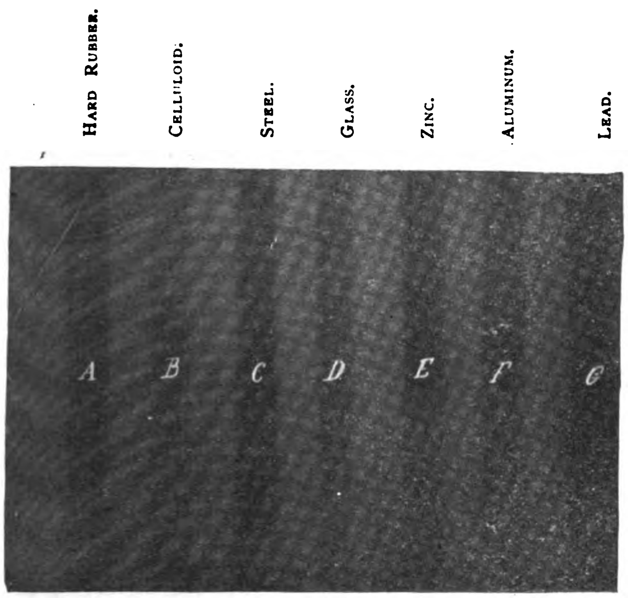

FIG. 2.—CATHODOGRAPH PRINT SHOWING VARYING PERMEABILITY OF DIFFERENT SUBSTANCES TO THE X-RAYS.

has been found to heat greatly, and to interfere with the results. Besides aluminum disks, Mr. Edison has also tried carbon, which he finds will permit of almost any amount of current being sent through the bulb, but for some, as yet unexplained, reason the carbon disks appear to offer a tremendous internal resistance, and become white hot, so that they cannot be employed for the purpose, and all Mr. Edison's experiments have thus far been made with aluminum disks as terminals.

Through the courtesy of Mr. Edison we were permitted to witness the exhaustion of the bulbs, in the pump room of the Edison laboratory, and as the process may be of interest to others experimenting in this line, we deem it well to give it in some detail. The bulb is put on the pump, and immediately below is placed a ring carrying a large number of small gas jets, so placed as to heat the bulb during the first stages of the process of exhaustion. This heat is necessary in order to drive out the air, which is condensed on the interior wall of the glass bulb, and which cannot be gotten rid of by any amount of exhaustion, and if not expelled by heat is always sure to give trouble as soon as the lamp is taken off the pump.

While the exhaustion is being carried on Mr. Edison passes through the bulb the discharge from an induction coil, giving a 4-inch spark, the primary of which is fed by six storage cells, and the circuit broken by a solid break-wheel, giving 100 breaks per second. This break-wheel consists of a solid brass disk, $\frac{1}{4}$ of an inch thick, with the teeth so arranged that the period of closure of the circuit is twice that of opening. Across the make and break terminals Mr. Edison inserts an 8-microfarad condenser.

The lamp being mounted and the pump started, the first phenomenon observed is a thin stream of purplish sparks between the terminals, which stream gradually becomes thicker and thicker in form, resembling a band. This discharge passes merely from the edge of one disk to that of the other. The next prominent change, as the exhaustion proceeds, is the appearance of a violet glow around the upper electrode, and a similar glow over a part of the surface of the lower terminal; this finally increases until both terminals are surrounded by the glow which gradually increases until the whole bulb is filled with the glow which becomes lighter and lighter in color, approaching to a milky whiteness. This continues for about a minute, when a dark space begins to form upon the lower terminal, increasing in size until finally the whole interior of the bulb becomes dark, and the glass alone fluoresces. It is immediately after this stage is reached that Mr. Edison finds it most advantageous to seal off the bulb of the pump, having in view the size of the bulb employed by him, and the potential employed. In order to obtain the vacuum just described, in bulbs of the size indicated, only from eight to ten minutes are required. Where higher exhaustion is employed higher potential must, according to Mr. Edison, be used, in order to effect the same results; but, as Mr. Edison points out, a bulb in connection with a 3-inch spark coil need only to be exposed a correspondingly longer time in order to effect the same photographic results as a bulb operated at higher potential.

Mr. Edison has thus far only experimented with bulbs containing atmospheric air, but expects shortly to fill the bulb with hydrogen and exhaust it, and believes that it will prove to be a more sensitive vacuum, and to show an increase in the effect sought for.

Among the interesting work already accomplished by Mr. Edison is that shown in the engraving, Fig. 2, made directly from a plate taken by means of the Roentgen X-rays, in Mr. Edison's laboratory. These represent the print obtained by the rays passing through various substances, which are designated by the letters marked upon the strips as follows: A, hard rubber; B, celluloid; C, steel; D, glass; E, zinc; F, aluminum; G, lead. These strips were all of the same size, about $\frac{1}{8}$ of an inch thick, so that a comparison can be made as to the permeability to passage of the various materials to the X-rays. Thus, it is curious to note that the best of all is celluloid, which seems to offer very little resistance to the path of the rays, while glass shows almost as much opacity to the rays as steel.

Besides the handiness of the form of bulb used by Mr. Edison, it has another quality to recommend it, namely, its cheapness. It is evident that such vacuum bulbs could be made and sold at a profit for 50 cents.

ON A NEW KIND OF RAYS.[1]

(1) A DISCHARGE from a large induction coil is passed through a Hittorf's vacuum tube, or a well-exhausted Crookes' or Lenard's tube. The tube is surrounded by a fairly close-fitting shield of black paper; it is then possible to see, in a completely darkened room, that paper covered on one side with barium platinocyanide lights up with brilliant fluorescence when brought into the neighborhood of the tube, whether the painted side or the other be turned towards the tube. The fluorescence is still visible at two metres distance. It is easy to show that the origin of the fluorescence lies within the vacuum tube.

(2) It is seen therefore that some agent is capable of penetrating black cardboard, which is quite opaque to ultra-violet light, sunlight or arc-light. It is therefore of interest to investigate how far other bodies can be penetrated by the same agent. It is readily shown that all bodies possess this same transparency, but in very varying degrees. For example, paper is very transparent; the fluorescent screen will light up when placed behind a book of a thousand pages; printer's ink offers no marked resistance. Similarly the fluorescence shows behind two packs of cards; a single card does not visibly diminish the brilliancy of the light. So, again, a single thickness of tinfoil hardly casts a shadow on the screen; several have to be superposed to produce a marked effect. Thick blocks of wood are still transparent. Boards of pine two or three centimetres thick absorb only very little. A piece of sheet aluminum, 15 mm. thick, still allowed the X-rays (as I will call the rays, for the sake of brevity) to pass, but greatly reduced the fluorescence. Glass plates of similar thickness behave similarly; lead glass is, however, much more opaque than glass free from lead. Ebonite several centimetres thick is transparent. If the hand be held before the fluorescent screen, the shadow shows the bones darkly, with only faint outlines of the surrounding tissues.

Water and several other fluids are very transparent. Hydrogen is not markedly more permeable than air. Plates of copper, silver, lead, gold and platinum also allow the rays to pass, but only when the metal is thin. Platinum .2 mm. thick allows some rays to pass; silver and copper are more transparent. Lead 1.5 mm. thick is practically opaque. If a square rod of wood 20 mm. in the side be painted on one face with white lead, it casts little shadow when it is so turned that the painted face is parallel to the X-rays, but a strong shadow if the rays have to pass through the painted side. The salts of the metals, either solid or in solution, behave generally as the metals themselves.

(3) The preceding experiments lead to the conclusion that the density of the bodies is the property whose variation mainly affects their permeability. At least no other property seems so marked in this connection. But that the density alone does not determine the transparency is shown by an experiment wherein plates of similar thickness of Iceland spar, glass, aluminum, and quartz were employed as screens. Then the Iceland spar showed itself much less transparent than the other bodies, though of approximately the same density. I have not remarked any strong fluorescence of Iceland spar compared with glass (see below, No. 4).

(4) Increasing thickness increases the hindrance offered to the rays by all bodies. A picture has been impressed on a photographic plate of a number of superposed layers of tinfoil, like steps, presenting thus a regularly increasing thickness. This is to be submitted to photometric processes when a suitable instrument is available.

(5) Pieces of platinum, lead, zinc and aluminum foil were so arranged as to produce the same weakening of the effect. The annexed table shows the relative thickness and density of the equivalent sheets of metal:

	Thickness.	Rel. Thickness.	Density.
Platinum	.018 mm.	1	21.5
Lead	.050 „	3	11.3
Zinc	.100 „	6	7.1
Aluminum	3.500 „	200	2.6

From these values it is clear that in no case can we obtain the transparency of a body from the product of its density and thickness. The transparency increases much more rapidly than the product decreases.

(6) The fluorescence of barium platinocyanide is not the only noticeable action of the X-rays. It is to be observed that other bodies exhibit fluorescence, e. g. calcium sulphide, uranium glass, Iceland spar, rock-salt, etc.

Of special interest in this connection is the fact that photographic dry plates are sensitive to the X-rays. It is thus possible to exhibit the phenomena so as to exclude the danger of error. I have thus confirmed many observations originally made by eye observation with the fluorescent screen. Here the power of the X-rays to pass through wood or cardboard becomes useful. The photographic plate can be exposed to the action without removal of the shutter of the dark slide or other protecting case, so that the experiment need not be conducted in darkness. Manifestly, unexposed plates must not be left in their box near the vacuum tube.

It seems now questionable whether the impression on the plate is a direct effect of the X-rays, or a secondary result induced by the fluorescence of the material of the plate. Films can receive the impression as well as ordinary dry plates.

I have not been able to show experimentally that the X-rays give rise to any calorific effects. These, however, may be assumed, for the phenomena of fluorescence show that the X-rays are capable of transformation. It is also certain that all the X-rays falling on a body do not leave it as such.

The retina of the eye is quite insensitive to these rays; the eye placed close to the apparatus sees nothing. It is clear from the experiments that this is not due to want of permeability on the part of the structures of the eye.

(7) After my experiments on the transparency of increasing thicknesses of different media, I proceeded to investigate whether the X-rays could be deflected by a prism. Investigations with water and carbon bisulphide in mica prisms of 30° showed no deviation either on the photographic or the fluorescent plate. For comparison, light rays were allowed to fall on the prism as the apparatus was set up for the experiment. They were deviated 10 mm. and 20 mm. respectively in the case of the two prisms.

With prisms of ebonite and aluminum, I have obtained images on the photographic plate, which point to a possible deviation. It is, however, uncertain, and at the most would point to a refractive index 1.05. No deviation can be observed by means of the fluorescent screen. Investigations with the heavier metals have not as yet led to any result, because of their small transparency and the consequent enfeebling of the transmitted rays.

On account of the importance of the question it is desirable to try in other ways whether the X-rays are susceptible of refraction. Finely powdered bodies allow in thick layers but little of the incident light to pass through, in consequence of refraction and reflection. In the case of the X-rays, however, such layers of powder are for equal masses of substance equally transparent with the coherent solid itself. Hence we cannot conclude any regular reflection or refraction of the X-rays. The research was conducted by the aid of finely-powdered rock-salt, fine electrolytic silver powder, and zinc dust already many times employed in chemical work. In all these cases the result, whether by the fluorescent screen or the photographic method, indicated no difference in the transparency between the powder and the coherent solid.

It is, hence, obvious that lenses cannot be looked upon as capable of concentrating the X-rays; in effect, both an ebonite and a glass lens of large size prove to be without action. The shadow photograph of a round rod is darker in the middle than at the edge; the image of a cylinder filled with a body more transparent than its walls exhibits the middle brighter than the edge.

(8) The preceding experiments, and others which I pass over, point to the rays being incapable of regular reflection. It is, however, well to detail an observation which at first sight seemed to lead to an opposite conclusion.

I exposed a plate, protected by a black paper sheath, to the X-rays, so that the glass side lay next to the vacuum tube. The sensitive film was partly covered with star-shaped pieces of platinum, lead, zinc and aluminum. On the developed negative the star-shaped impression showed dark under platinum, lead, and, more markedly, under zinc; the aluminum gave no image. It seems, therefore, that these three metals can reflect the X-rays; as, however, another explanation is possible, I repeated the experiment with this only difference, that a film of thin aluminum foil was interposed between the sensitive film and the metal stars. Such an aluminium plate is opaque to ultra-violet rays, but transparent to X-rays. In the result the images appeared as before, this pointing still to the existence of reflection at metal surfaces.

If one considers this observation in connection with others, namely, on the transparency of powders, and on the state of the surface not being effective in altering the passage of the X-rays through a body, it leads to the probable conclusion that regular reflection does not exist, but that bodies behave to the X-rays as turbid media to light.

Since I have obtained no evidence of refraction at the surface of different media, it seems probable that the X-rays move with the same velocity in all bodies, and in a medium which penetrates everything, and in which the molecules of bodies are embedded. The molecules obstruct the X-rays, the

1. By W. C. Röntgen. Translated by Arthur Stanton from the Sitzungsberichte Würzburger Physik-Medic. Gesellschaft, 1895.

more effectively as the density of the body concerned is greater.

(9) It seemed possible that the geometrical arrangement of the molecules might affect the action of a body upon the X-rays, so that, for example, Iceland spar might exhibit different phenomena according to the relation of the surface of the plate to the axis of the crystal. Experiments with quartz and Iceland spar on this point lead to a negative result.

(10) It is known that Lenard, in his investigations on kathode rays, has shown that they belong to the ether, and can pass through all bodies. Concerning the X-rays the same may be said.

In his latest work Lenard has investigated the absorption coefficients of various bodies for kathode rays, including air at atmospheric pressure, which gives 4.10, 3.40, 3.10 for 1 cm., according to the degree of exhaustion of the gas in discharge tube. To judge from the nature of the discharge, I have worked at about the same pressure, but occasionally at greater or smaller pressures. I find, using a Weber's photometer, that the intensity of the fluorescent light varies nearly as the inverse square of the distance between screen and discharge tube. This result is obtained from three very consistent sets of observations at distances of 100 and 200 mm. Hence air absorbs the X-rays much less than the kathode rays. This result is in complete agreement with the previously described result, that the fluorescence of the screen can be still observed at 2 metres from the vacuum tube. In general, other bodies behave like air; they are more transparent for the X-rays than for the kathode rays.

(11) A further distinction, and a noteworthy one, results from the action of a magnet. I have not succeeded in observing any deviation of the X-rays even in very strong magnetic fields.

The deviation of kathode rays by the magnet is one of their peculiar characteristics; it has been observed by Hertz and Lenard, that several kinds of kathode rays exist, which differ by their power of exciting phosphorescence, their susceptibility of absorption, and their deviation by the magnet; but a notable deviation has been observed in all cases which have yet been investigated, and I think that such deviation affords a characteristic not to be set aside lightly.

(12) As the result of many researches, it appears that the place of most brilliant phosphorescence of the walls of the discharge-tube is the chief seat whence the X-rays originate and spread in all directions; that is, the X-rays proceed from the front where the kathode rays strike the glass. If one deviates the kathode rays within the tube by means of a magnet, it is seen that the X-rays proceed from a new point; i. e., again from the end of the kathode rays.

Also for this reason the X-rays, which are not deflected by a magnet, cannot be regarded as kathode rays which have passed through the glass, for that passage cannot according to Lenard, be the cause of the different deflection of the rays. Hence I conclude that the X-rays are not identical with the kathode rays, but are produced from the kathode rays at the glass surface of the tube.

(13) The rays are generated not only in glass. I have obtained them in an apparatus closed by an aluminum plate 2 mm. thick. I purpose later to investigate the behavior of other substances.

(14) The justification of the term "rays," applied to the phenomena, lies partly in the regular shadow pictures produced by the interposition of a more or less permeable body between the source and a photographic plate or fluorescent screen.

I have observed and photographed many such shadow pictures. Thus, I have an outline of part of a door covered with lead paint; the image was produced by placing the discharge tube on one side of the door, and the sensitive plate on the other. I have also a shadow of the bones of the hand, of a wire wound upon a bobbin, of a set of weights in a box, of a compass card and needle completely enclosed in a metal case, of a piece of metal where the X-rays show the want of paper. It is faint, but unmistakeable.

For the rectilinear propagation of the rays, I have a pin-hole photograph of the discharge apparatus covered with black paper. It is faint, but unmistakeable .

(15) I have sought for interference effects of the X-rays, but possibly, in consequence of their small intensity, without result.

(16) Researches to investigate whether electrostatic forces act on the X-rays are begun but not yet concluded.

(17) If one asks, what then are these X-rays; since they are not kathode rays, one might suppose, from their power of exciting fluorescence and chemical action, them to be due to ultra-violet light. In opposition to this view a weighty set of considerations presents itself. If X-rays be indeed ultra-violet light, then that light must possess the following properties.

(a) It is not refracted in passing from air into water, carbon bisulphide, aluminum, rock-salt, glass or zinc. (b) It is incapable of regular reflection at the surfaces of the above bodies. (c) It cannot be polarized by any ordinary polarizing media. (d) The absorption by various bodies must depend chiefly on their density.

That is to say, these ultra-violet rays must behave quite differently from the visible, infra-red, and hitherto known ultra-violet rays.

These things appear so unlikely that I have sought for another hypothesis. A kind of relationship between the new rays and light rays appears to exist; at least the formation of shadows, fluorescence, and the production of chemical action point in this direction. Now it has been known for a long time, that besides the transverse vibrations which account for the phenomena of light, it is possible that longitudinal vibrations should exist in the ether, and, according to the view of some physicists, must exist. It is granted that their existence has not yet been made clear, and their properties are not experimentally demonstrated. Should not the new rays be ascribed to longitudinal waves in the ether?

I must confess that I have in the course of this research made myself more and more familiar with this thought, and venture to put the opinion forward, while I am quite conscious that the hypothesis advanced still requires a more solid foundation.

PROF. ROENTGEN'S DISCOVERY.[1]

BY A. A. C. SWINTON.

WORKING upon the line indicated in the telegrams from Vienna, recently published in daily papers, I have, with the assistance of Mr. J. C. M. Stanton, repeated many of Professor Roentgen's experiments with entire success. According to one of our first experiments, an ordinary gelatinous bromide dry photographic plate was placed in an ordinary camera back. The wooden shutter of the back was kept closed and upon it were placed miscellaneous articles, such as coins, pieces of wood, carbon, ebonite, vulcanized fiber, aluminum, etc., all being quite opaque to ordinary light. Above was supported a Crookes tube, which was excited for some minutes. On development, shadows of all the articles placed on the side were clearly visible, some being more opaque than others. Further experiments were tried with thin plates of aluminum or of black vulcanized fiber, interposed between the objects to be photographed and the sensitive surface, this thin plate being used in place of the wood of the camera back. In this manner sharper shadow pictures were obtained. While most thick metal sheets appear to be entirely opaque to the radiations, aluminum appears to be relatively transparent. Ebonite, vulcanized fiber, carbon, wood, cardboard, leather and slate are all very transparent, while, on the other hand, glass is exceedingly opaque. Thin metal foils are moderately opaque, but not altogether so.

As tending to the view that the radiations are more akin to ultra-violet than to infra-red light, it may be mentioned that a solution of alum in water is distinctly more transparent to them than a solution of iodine in bisulphide of carbon.

So far as our own experiments go, it appears that, at any rate, without very long exposures, a sufficiently active excitation of the Crookes tube is not obtained by direct connection to an ordinary Rhumkorff induction coil, even of a large size. So-called high frequency currents, however, appear to give good results, and our own experiments have been made with the tube excited by current obtained from the secondary circuit of a Telsa oil coil, through the primary of which were continuously discharged twelve half-gallon Leyden jars, charged by an alternating current of about 20,000 volts pressure, produced by a transformer with a spark-gap across its high-pressure terminals.

For obtaining shadow photographs of inanimate objects and for testing the relative transparency of different substances, the particular form of Crookes tube employed does not appear to greatly signify, though some forms are, we find, better than others. When, however, the human hand is to be photographed, and it is important to obtain sharp shadows of the bones, the particular form of tube used and its position relative to the hand and sensitive plate appear to be of great importance. So far, owing to the frequent destruction of the tubes, due to overheating of the terminals, we have not been able to ascertain exactly the best form and arrangement for this purpose, except that it appears desirable that the electrodes in the tube should consist of flat and not curved plates, and that these plates should be of small dimensions.

A living human hand was exposed for twenty minutes through an aluminum sheet .0075 in thickness, the Crookes tube, which was one of the kind containing some white phosphorescent material (probably sulphide of barium), being held

[1] Abstract from "Nature."

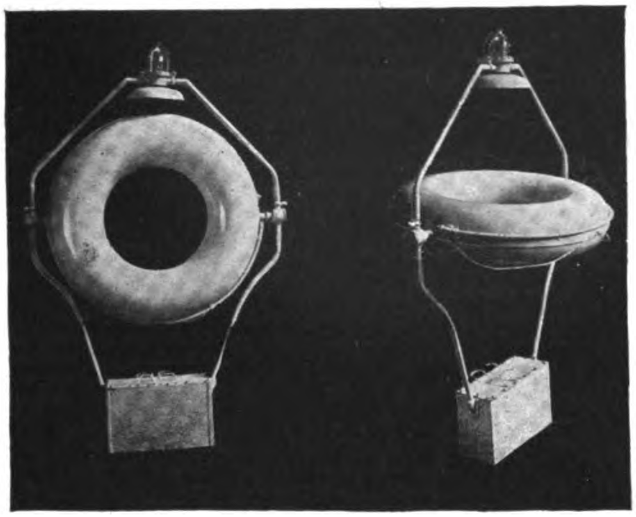
vertically upside down, with its lowest point about two inches above the center of the hand.

By substituting a thin sheet of black vulcanized fiber for the aluminum plate, we have since been able to reduce the exposure required to four minutes. Indeed, with the aluminum plate, the twenty minutes' exposure appears to have been longer than was necessary. Further, having regard to the great opacity of glass, it seems probable that where ordinary Crookes tubes are employed, a large proportion of the active radiations must be absorbed by the glass of the tube itself. If this is so, by the employment of a tube partly constructed of aluminum, as used by Lenard, the necessary length of exposure could be much reduced.

THE GUEST-BATES ELECTRIC LIFE BUOY.

OUR engraving represents a novel electric life buoy, which has been tested on board the lighthouse tender "Armeria," Commander West, United States Navy, and favorably reported upon to the Lighthouse Board.

The buoy consists of a ring mounted in a framework of metal



FIGS. 1 AND 2.—THE GUEST-BATES ELECTRIC LIFE BUOY.

tubing. The ring is normally in the plane of the frame. When the buoy is dropped into the water the ring on which the buoy floats turns so as to rest with its side on the water, and on so turning operates an automatic switch controlling the lights in the manner described below. At the lower end of the frame is the battery box, containing the cells. To keep this perfectly dry inside, a moisture absorber is placed there with the cells. The box cover is easily removable and made water-tight by a packing of rubber with wax or tar. The framework passes from the ends of the battery box upward, meeting to form an arch above the ring. On top of this arch is the lantern, a glass globe covering one or more pairs of incandescent lamps. Electrical connection between these lamps and battery cells are through the tubes of the framework on both sides. On each side of the frame is a switch box, containing the automatic switch controlling the circuit.

The ring is mounted upon trunnions journaled in the switch boxes. Where the trunnion enters the switch box it is surrounded by a water-tight stuffing box to better protect the switch. The stationary contacts of the switch are secured to the frame and box and the movable contacts are secured to the ring trunnions, but, of course, both sets of contacts are insulated from their supports. These contacts are so related to each other that the turning of the ring but a very small angle out of the plane of the frame will close the circuit and light the lamps, which will remain in circuit until the ring can be turned around nearly one complete revolution. This precaution is very important, because it insures the continuous glow of the lamps in a rough sea.

Such are the principal features of the machine. There are a few other interesting details added. One is a hand switch concentric with the lantern, added merely for precaution. It is so arranged as to be able to switch on one pair of lamps at a time, or turn off all of them. The lamps are in parallel and are used two at a time to economize battery power. If one lamp of any given pair gives out the other can supplement it until another pair of lamps can be switched on. Another addition is a bell below the lantern, automatic or other, which will be of value as a fog signal. The handle of the hand switch is surrounded by a water-tight stuffing box, like that of the automatic switch.

A very interesting problem here is that of battery power. The lamps will be from 3 to 8 volt, from ½ to 8, or more, candle power, and in every case will take about 1 ampere of current. The improvements in dry batteries of late years have been so great that the market can now furnish cells of which six in multiple series of three can glow continuously a couple of 1-candle power lamps one hour. Connected in the same way, eighteen such cells can glow these lamps three hours, and thirty-six of them can glow the same lamp six hours. More hours can be gotten by adding cells, but the latter case will be amply sufficient for most work. For lamps of large candle power for use a longer time a storage battery is at present recommended, having easy access to a dynamo to charge them up every two or three months. Accumulators are now so well made that they will lose but 20 per cent. of their charge by standing in a place kept dry as the buoy battery box will be. Hence, on a steamer which almost always has its dynamo, the care of cells is an easy matter. There is now being designed a salt-water battery of such power that it will glow a strong light for several whole nights continuously when overboard, its capacity being large, without occupying much room.

The Guest-Bates device is being exploited by the Guest-Bates Marine Life Saving Appliance Company, of this city.

ANOTHER ANALYSIS OF THE DETROIT MUNICIPAL FIGURES.

Mr. C. Livingston, well known in lighting affairs at St. Paul, Minn., where he has large interests, has written as follows to the "Detroit Free Press" on the subject of the recent municipal plant figures. It will be remembered that certain items have already been discussed, pro and con, in "The Electrical Engineer," but Mr. Livingston makes additional points in his argument:

In your issue of Friday, January 10, you give the average cost per lamp per month of the public arc lights of the City of Detroit at $7.20. I am always at a loss to know what advantage it is to an individual or a municipality to deceive him, or itself, which you certainly do and which Detroit certainly does in the statement you publish. In the detailed statement of the cost of operating the public light plant which you give, the question of depreciation of the plant, insurance, water and also taxes are all eliminated. The figure $1.34 is the interest charge per lamp per month. If I am correctly informed, the plant cost $650,000. Interest even at 4 per cent. would amount to $1.46 instead of $1.34 per lamp per month. Taking, however, your own figures of $1.34, plus $5.86 for the items you mention, gives the figure you state, $7.20 per lamp per month. I am informed that the value of the real estate is $145,000. Taking this from the total cost of the plant ($650,000) would leave $505,000 as the cost of the machinery. It is the consensus of opinion of the best electrical experts that depreciation in electrical machinery is at least 10 per cent. a year. Say, however, the value of the machinery is $400,000; 10 per cent of this is $40,000; to this add the cost of insurance, say 1½ per cent. on $545,000, which is much below the going rate of insurance on electrical machinery, and you have the total cost of these two items, $48,-175, which divided by 1,483, average of lamps in use during the months you enumerate, would give the cost per lamp per year as $32.48; dividing this again by 12 and you find the cost per lamp per month is $2.70 for these items; adding this to the $7.20 as given above, gives us $9.90 per month as the cost of each arc lamp. Multiplying this by 12 (the number of months in the year) gives us the cost per year for every arc lamp at $118.80. If the interest figure which I give above as $1.46 is correct, the cost per year would be $120.24. I am told that the assessed value of property in Detroit is about 80 per cent. of its real value, on which the city receives a tax of 2 per cent. If this be true, the assessed value of your electric lighting plant would be $520,000, 2 per cent. on which is $10,400. The loss of this tax should be added to the cost of your lights, for the reason that if the municipality did not own its own plant, some private corporation would, and the city would receive the tax above stated. There are various other items of expense which experience shows every electric light plant, whether owned by individuals or municipalities, are the natural sequences of the business, such as patent and personal damage suits. In fact, in a railroad company, of which I am a director, 5 per cent. of our gross earnings is credited to the fund to pay for personal damages each year, and the amount so credited does not equal the amount paid for personal damages, and in an electric lighting company that I was formerly connected with, in a much smaller town than Detroit, in eleven years' time the smallest amount paid for personal damage cases in the form of legal expenses and settlements, in any one year, was in excess of $6,000.

CATHODOGRAPHS WITHOUT CROOKES TUBES.

BY WILLARD E. CASE.

WHILE experimenting with the new method of photographing hidden objects by the Roentgen method, with cathode rays from the Crookes tube, the writer discovered that he could do away with the tube entirely. The experiment is somewhat as follows:

A sensitive photographic plate, in its paper case, was placed between two metallic plates, placed 6 inches apart, which were connected with the terminals of an induction coil giving a ½-inch spark, and on this paper case there was laid a piece of metal which was covered with another piece of paper. The plate was thus exposed for about fifteen minutes. On the plates being developed, it was found that a picture of the metal piece had been photographed on the plate.

Afterwards another sensitive plate, inclosed in a paper box, was placed, not between the two metal plates, but back of one of them, and left for about fifteen minutes, while the rays were passing between the two plates.

On developing the plate a picture, or, rather shadow, of one of the metal plates was found on the photographic plate, which would tend to show that the rays pass in straight lines from one plate to the other, and those going past the plate, into space, acted on the sensitive plate beyond.

If these rays can be thrown to a distance, what tremendous possibilities it may open up, as hidden objects could be photographed in absolute darkness at a distance only limited by the distance at which the rays may act. And so might shadows be thrown, by which new methods of communication could be made.

Another interesting fact noted was that on placing a vacuum tube in the vicinity of the condenser plate and the sensitive photographic plate the rays seemed to be deflected, giving an imperfect image of the edge of the plate.

LETTERS TO THE EDITOR.

THE POLICY OF CITY OWNERSHIP.

I note in this week's issue Mr. Dow's further discussion of the Detroit municipal lighting plant, together with his comments on my communication on the subject.

There is little further to be said in the matter. Inasmuch as none of the statements of fact are called into question, it would only be a waste of words to discuss what may occur in the future other than to reiterate what was stated before, viz., that it is a well-known fact that public enterprises under municipal control and management are not conducted on as economical a basis as when administered by individuals or private corporations.

Of course, rare exceptions may and do exist on both sides, which simply prove the rule. If municipal affairs were always administered by the best citizens with the sole purpose in view of producing the best results for the taxpayers, there would be no occasion for discussing this subject.

Whether Detroit will be able to break the record and prove to be a shining example in the administration of public enterprises, rather than to repeat her record, which is fair, compared with that of other cities, the future alone will tell us.

The record in Chicago, which is only for a period of seven years, is open for investigation and speaks plainly for itself, confirming all and more than has been said against municipal ownership of lighting plants.

There is no question in my mind about Mr. Dow's intentions or desire to do that which is right and to the best interests of his employers, and the fact that he is employed by a municipality will make him none the less efficient in endeavoring to do what he believes to be right in the management of the property under his charge. But that he can control the situation so as to produce his anticipated results is not to be reasonably expected by any one who has given any attention to the outcome of municipal management of property of this character.

Boston, Mass., Feb. 1. JAS. I. AYER.

CATHODE PENUMBRAS.

Is it not possible that the so-called cathodic rays, while not subject to the ordinary laws of refraction, may under proper conditions yield to analysis by diffraction? I am led to this query by noticing in Professor Wright's print of three spheres in a box, a very marked penumbra about each shadow. May not this be caused by diffraction? It would be necessary in order that this should be so that the wave front should be changed by the difference in intensity of the light passing by and through the sphere.

J. B. HENCK, JR.

Brooklyn, N. Y.

"ON HIS BASE."

Referring to our friend Jenks' opinion on lamp bases, it occurs to the writer that it would be well to patronize companies who produce lamps that do not droop, inasmuch as there are several manufacturers offering products embracing this excellent point. Furthermore a sign or display of several thousand lamps ranging from 20 to 150 feet from the ground affords quite a substantial argument against the turning process as advocated by our disciple of the pinnacle base. This turns the Philadelphia gentleman's argument in favor of the Edison base. OLIVER E. BRASTOW.

Boston, Mass.

USEFUL TO ENGINEERS AND INVESTORS.

I beg you to let me take this opportunity to congratulate you most heartily upon your issue of Jan. 8, as well as upon your paper as a whole.

Your articles from time to time descriptive of central stations and central station management are of the greatest possible value; and I believe investors in electrical enterprises generally place the highest value upon your careful and conservative analysis of the balance sheets of our various large electrical corporations. Your paper keeps well abreast of the times in regard to technical matters, and I look for each weekly issue with extreme interest. The work you have done, and are doing, deserves the gratitude of all members of our profession. R. B. OWENS, Prof. of Elec. Eng.

Dept. of Elec. Eng., University of Nebraska.

A SPECIALTY OF THE "ENGINEER."

I am glad to say to you that I prize most highly the truly pre-eminent speciality of "The Electrical Engineer" of describing and illustrating central stations. Mr. Wetzler's recent article on the New York Edison stations has most especially pleased me. HARRIS J. RYAN, Professor of Elec. Eng.

Cornell University, Ithaca, New York.

A CATHODOGRAPH SUGGESTION.

I have been much interested recently in the Röntgen method of photography, and a very strong suspicion has entered my mind that it is not light that acts on the sensitive plates, but is a heretofore unknown property of electrical vibrations of high frequency and voltage. Perhaps the same results may be accomplished by connecting the terminals of a Tesla coil to sheets of metal, placed on opposite sides of the camera and the subject to be photographed, though I do not think that the failure of this experiment would disprove the supposition. The discovery appears to depart from all known laws of light, while electrically I do not know of any law with which it disagrees. I may be wrong in my surmises, but I think that the idea deserves a thorough consideration before being thrown over. At best, it appears to be all a matter of guesswork at present. HARRY E. DEY.

New York, Feb. 4, 1896.

(This letter, it will be seen, was written before the issuance of our Feb. 5 issue, containing the account of Dr. Morton's experiments.—Eds. E. E.)

CONVENIENT AND VALUABLE.

We beg to acknowledge receipt of the cloth-filing case for the little data sheets, and thank you for the same. By the way, these little sheets have been found to contain a lot of valuable information in a convenient form.

SUPPLEMENT.

ELECTRIC UNDERGROUND TRACTION FOR NEW YORK CITY.

THE New York Supreme Court Rapid Transit Commissioners who have been investigating the subject of the proposed underground road, are said to have reached the close of their labors. The reports printed in the daily papers show that they have received a large amount of testimony of the usual contradictory nature, which might well have left them with confused ideas and puzzled minds on almost all the points connected with the great scheme. Curiously enough, even the ability of electricity to handle the traffic has been made a special feature of controversial evidence, reading some of which makes one wonder whether electric motors have ever yet hauled a single passenger anywhere. It might seem that at this late day, when electric traction has not only a virtual monopoly of street railway work, but is competing with steam locomotion on cross-country roads, arguments against electricity would have little weight, and that the existence of the facts would be conceded. But that lingering prejudice has strength must be inferred from the attitude of the "Evening Post," of this city, which, although an avowed advocate of the underground road, collated recently with much care and ability all the data going to show that electricity could not be depended upon as a motive power. In short, a desire to be fair had apparently led the "Post" into the position of taking the pessimistic view on every one of the points raised—power, speed, frequency, braking, signaling, etc.; and the result was, as we happen to know, serious discouragement to many people.

At such a juncture it is fortunate that Mr. Frank J. Sprague has allowed himself to make, in an excellent interview in the same paper, a full exposition of his own views and beliefs on the subject. It is a most timely publication, if only as proving that the same facts are often capable of being regarded from diametrically opposite standpoints. But it goes much further than giving a right aspect to existing conditions, or a correct interpretation to technical data. It unfolds a broad plan for securing the desideratum so long under wearisome discussion, and, to us at least, shows that, be the method of raising the capital what it may, the system of propulsion is not an element of uncertainty, but a feature whose success should be treated as a foregone conclusion.

To those who are not familiar with Mr. Sprague's work, his brisk alertness in the defence of electricity may be remindful of the cartoon which represented Mr. Gladstone as a terrier pricking up its ears on the mere whispering of the word "Atrocities;" but the impression made by the article in the "Post" was in some ways most regrettable, and it needed prompt refutation by somebody entitled to public confidence. Mr. Sprague speaks with all the authority of long experience, fertile invention and brilliant success, and his admirable review of the case must have convinced the public that electricity is ready to run the road as soon as the road is ready to run. As for the plans underlying Mr. Sprague's statement, we may say that they have already been noted by us in a recent article and comprise single car units, but we may briefly quote him here as to details:

The control is unique. Each car is equipped not only with its own motor, but also at each end with a duplicate controlling device, operating not only the motor control, but an auto-

matic brake, and being itself automatic in action under certain emergency conditions. Such a device has been practically and fully tested under the severest conditions. When desired, two or three, or even six cars, can be indiscriminately coupled together, in any order, at any part of the line, without head-and-tail switching, and, all other controllers being for the time thrown out of action, the leading car platform is made the place of simultaneous control of all car motors and brakes, or at will any selected one of twelve places, that is, either end of any of the six cars in the train, can be made the controlling point. Simultaneous control of a number of machines of the required power has already been practically demonstrated, and I am preparing to make a demonstration of such a system in actual operation. Current will undoubtedly be supplied by continuous rail contact, using either a side or a middle rail, slightly elevated, or, preferably, a rigid overhead rail secured to insulators in the roof of the tunnel and following the middle line of all tracks and switches, the car thus running, as it were, between two electric planes of practically constant difference of potential, making a flexible overhead and running rail contact, and free to follow without difficulty any combination of tracks and switches. This is the plan I suggested for the underground railroad of London as early as 1882, and I see no reason for changing it.

By a happy coincidence, the interview with Mr. Sprague appeared the same day that the commissioners had before them Mr. David L. Barnes, the well-known railroad engineer, representing the Westinghouse-Baldwin interests, who also threw the weight of his authority on the side of electricity, speaking from the manufacturers' standpoint. He stated that an electric motor attached to six loaded cars could reach a speed of sixty miles an hour in forty-seven seconds, and within 2,700 feet of its starting point, and while going at that rate could be stopped within 1,500 feet. The cost of equipment for 20 express trains, with motor and five cars to each train, would be $330,000; 150 local trains, motor and three cars to each train, $1,720,000; conductors, $715,000; central station equipment, for express trains, $504,000; for locals, $1,380,000, a total cost of $4,649,000. With that equipment trains could be run at about three-minute headway for express trains, and from thirty to forty-five seconds for local trains. It will be noted, of course, that Mr. Barnes based his remarks on the locomotive method, rather than the "unit," but if the commission has any lingering doubts on the ability of electricity to haul either single cars or trains, it will certainly be a matter for genuine surprise.

CATHODOGRAPH METHODS.

NOT perhaps since the publication of Professor Crookes' memorable experiments on radiant matter has there been announced a scientific discovery more calculated to arouse the interest of the general public than that of Professor Roentgen. Scarcely a day has passed for the last few weeks without the record of some new experimenter at work or of the application, real or fantastic, of the "X-rays" to some purpose. Perhaps the most important advance made since the announcement by Professor Roentgen regarding this dark ray photography is that the process can be carried out without the intervention of a Crookes tube. This was proved experimentally by the work of Dr. W. J. Morton, described in our issue of last week, in which a record was obtained by placing the sensitive photographic plate between the two main conductors of a static electrical machine. A still further advance on these lines is that chronicled in this issue, and due to Mr. Willard E. Case, who has succeeded in obtaining distinct shadow effects from a comparatively small induction coil, at ordinary atmospheric pressures, and who suggests a possible method of utilizing the phenomenon in a practical way. One of the most gratifying manifestations of this new research is the interest which it has aroused among our celebrated inventors. In last week's issue Prof. Elihu Thomson gave some of his views on the subject, and this week supplements them by suggestions and sketches of apparatus for obtaining the best effects with the new method. We dare say that makers of scientific apparatus and other experimenters will not let the suggestions pass unheeded. Mr. Edison, also, has succumbed to the fascination of the X-rays and, dropping for the moment his magnetic ore separating processes, has plunged into the subject with his old-time energy and enthusiasm. Mr. Edison seems to hold views at variance with those heretofore generally accepted, as to the quality of the vacuum required to obtain the best emission of the X-rays; but as his opinion is based on the results of numerous experiments, they would appear to be entitled to full consideration. A very characteristic demonstration of the permeability to the X-rays of various substances is the reproduction of a cathodograph taken by Mr. Edison, which we print on another page. All the samples being taken under precisely similar conditions, the cathodograph gives an admirable graphical illustration of the relative value of the various materials as substances for the making of vacuum tubes to generate X-rays. It may be considered a trite remark to repeat that this new work opens up a wide field, regarded both scientifically and practically, but we are certain that even after the discovery has ceased to be the nine-days' wonder into which it has been converted by the daily press, it will occupy a prominent and lasting position in the annals of science.

MUNICIPAL ELECTRIC PLANTS.

IT would have been strange if the present New York Legislature had not seen some of the municipal lighting plant schemes that have been promoted everywhere else in the country; and we now note the introduction of a bill of this character in both the Senate and the Assembly. It provides that any city in this State may establish electric light plants for its own use and for the use of its citizens. No city shall have authority to exercise this power until granted by the Common Council by a majority vote and approved by the Mayor and ratified by the voters of the city. If refused ratification the matter shall not be resubmitted for at least two years. Cities establishing such plants are authorized to pay for the same by the issue of bonds, to be issued for not exceeding thirty years, and the bill also provides for appropriations each year to pay these bonds. The control of such plants is to be under the Common Council. The price to be charged for electricity is to be fixed at not less than cost, and must not net a profit exceeding 8 per cent. When existing electric light plants, owned by corporations, are sold to cities, such corporations shall cease to exist. A copy of the full text has not reached us, but the digest makes no mention of protection to existing investments by purchase of them at a reasonable price before the city plant is started. The authors of this bill may be well meaning, but we venture to recommend it to the notice of the new State Association, which can at once justify its existence and utility by educating public opinion against such schemes. The association has plenty of good work to do, but none better than this.

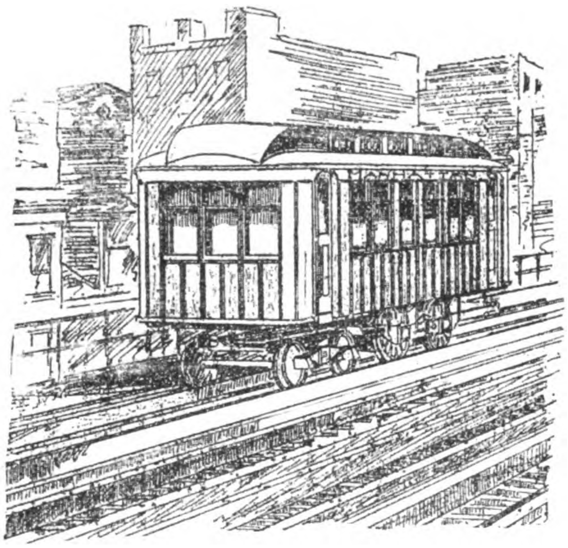
ELECTRIC TRANSPORTATION.

ELECTRICITY ON THE NEW YORK ELEVATED RAILROADS.—A COMBINATION OF THIRD RAIL AND STORAGE BATTERY TO BE TRIED.

AFTER an extended investigation the management of the New York Elevated Railway system have once more decided to experiment with a method of electric propulsion, and in this instance propose to give a trial to a system combining the third rail direct supply with the storage battery carried on the motor car.

This system, it is stated, has, among others, the following advantages: Greater speed in starting with less expenditure of energy, less vibration to the structure for the reason that the power is rotary; electric light and heat in cars; absence of smoke and steam; great economies in coal, cost of operation and maintenance of structure; absolute reliability of service, for either system may be relied upon to carry the train to its destination.

If adopted for all the lines the saving in the consumption and handling of coal, it is estimated, will amount to $900,000, equal to 3 per cent. on the capital stock, and the additional saving in repairs and maintenance of engines and in other important items will be equivalent to the interest charge incurred by the



NEW MOTOR CAR, MANHATTAN ELEVATED RAILROAD, NEW YORK

change of equipment, the total cost of which will amount to about $6,000,000.

The work of installation will be carried out by the Electric Storage Battery Company of Philadelphia, aided by the General Electric Company. An electric locomotive carrying motors on the axles and a storage battery plant in the cab of the locomotive will be used. The elevated structure will be equipped with a third rail to carry current to the trains. The storage battery on the locomotive and the motor will be connected in parallel with this third rail. Electric current will be conveyed by this third rail to the locomotive from a power station near the lines.

If adopted for all the lines, the main station will be situated outside the city limits, in order to secure the economy of cheap land and cheap fuel. In this station, machinery of large size and the highest possible efficiency will be used, which will generate alternating current at a high tension, which can be conveyed to sub-stations along the lines of the Elevated Road with very small loss in energy and cost for conductors. These sub-stations will reduce and transform the high tension alternating current into a low tension constant current with which the third rail will be fed.

The experiment will be made on the Thirty-fourth street branch line, and our illustration shows the type of motor car which will be used.

The battery locomotive will consist of the present locomotive frame, somewhat altered, with two G. E. 2,000 (500-volt) motors, mounted on the driving axles, the frame carrying a body which is similar in appearance to that of the regular cars, in which the batteries will be carried. These will consist of 248 cells, of 400 ampere-hours' capacity each, the total weight being 10 tons.

This battery is always in parallel with the third-rail connection with the power-house, and the speed of the car is controlled by the usual series-parallel combination of motors. The advantage of this system is that the batteries being in parallel with the third rail will keep the current in that conductor of a steady average value. What will be gained by this will be seen from the following data:

At present in the Elevated Railway service, the car no sooner obtains its maximum running speed than it must stop and shut down. A high speed over the line cannot be obtained except by a greater rate of acceleration in starting, and for this steam locomotives of the weight allowed on the structure cannot give the necessary drawbar pull. The average distance between stations of the Elevated Road is 1,700 feet. The average running time for this distance is 85 seconds.. The following data show the variation, maximum horsepower, maximum drawbar pull, maximum speed attained, braking distance of train from maximum speed and the horsepower hours per train-mile.

Power applied for 15 seconds: Maximum horsepower, 655; maximum drawbar pull necessary, 13,050 pounds; maximum speed, in miles per hour, 18¾; braking distance from maximum speed, 190 feet; horsepower hours per train-mile, 4¼.

Power applied for 32 seconds: Maximum horsepower, 364; maximum drawbar pull, 6,800 pounds; maximum speed, 20 miles an hour; braking distance, 215 feet; horsepower hours per mile, 5.

Power applied for 49 seconds: Maximum horsepower, 310; maximum drawbar pull, 5,170 pounds; maximum speed, 22.50; braking distance, 276 feet; horsepower hours per mile, 6.55.

Power applied for 58 seconds: Maximum horsepower, 324; maximum drawbar pull, 4,850 pounds; maximum speed, 25; braking distance, 340 feet; horsepower hours per mile, 8.1.

Power applied for 65 seconds: Maximum horsepower, 346; maximum drawbar pull, 4,775 pounds; maximum speed, 27.2; braking distance, 405 feet; horsepower hour per train mile, 9.65.

The average speed for all of these is 13.6 miles an hour, not including stops at stations.

The figures above show that if the power is applied to the train for a shorter length of time, a greater drawbar pull and greater maximum horsepower are necessary; but that the maximum speed to be attained is less, as the train runs for a considerable length of time at full speed without acceleration before commencing to slow down; that the braking distance in feet is less from maximum speed, thus giving a greater safety to the service; and that the energy to propel the train in this distance becomes considerably less by getting up the speed quickly. This is due to the fact that a

much less part of the momentum of the train is wasted at the brakeshoes in shutting down.

It will be seen that in order to get the most efficient service, it is necessary that a great deal of power should be applied for a short length of time. This in any sort of a straight trolley system would mean a very greatly varying load for the conductors and generating machinery, and far in excess of the average power would have to be installed. The storage battery on each train keeps the power supplied to the train of the average value, and allows of the installation of generating machinery and line conductors for only the average demand of the system.

The batteries on the locomotive have the advantage over batteries placed in the main station, or in substations, in that the regulation or voltage at the motors themselves is very much better. Any congestion of traffic means a distribution of battery in the same way; stationary batteries would each have to have capacity for maximum number of trains on their section.

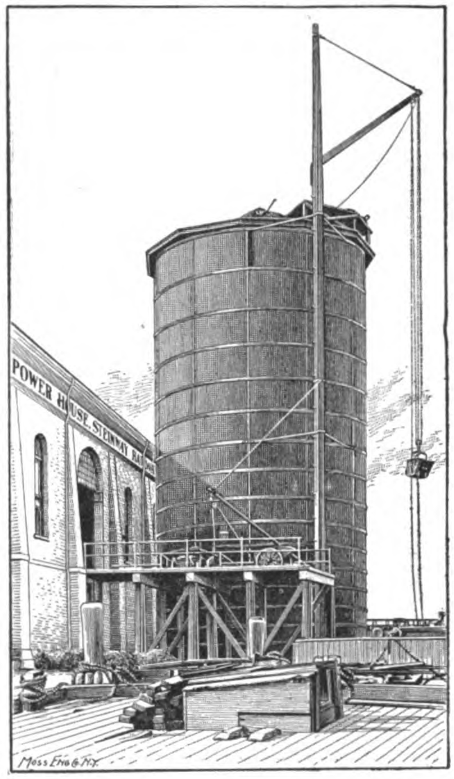
The batteries on the different locomotives are all connected in parallel by the third rail, so that they all work in unison for any variation of load in their immediate vicinity, and hence the amount of battery needed is less than if installed in sub-stations along the line. The weight of battery necessary on each locomotive is no more than is required for traction purposes, and the weight of the battery locomotive is calculated not to exceed that of the present steam locomotive.

The running of the third rail conductor will be made very simple, in that it need only be installed on a straight track. On curves, crossings, and in and out of car barns and locomotive house, the batteries do the work alone. The batteries have a capacity sufficient to run the train for about 25 miles without aid from the third rail conductor. It is understood that the batteries are never taken from the locomotive, as the average current maintained by the line charges the battery at times of light load equalling in amount what is discharged at times of heavy load.

In regular service the batteries will never be called upon to discharge more than 2 to 3 per cent. of their capacity before they are charged again, making the service perfectly easy on the battery; a very long life is anticipated for them in consequence. The reduction in the amount of coal burned over the present system is estimated at 60 per cent., and a very large saving in the present cost of handling coal.,

COAL HANDLING IN THE STEINWAY TROLLEY POWER HOUSE, ASTORIA, L. I.

A VERY important element in the designing and building of power plants is the question of the proper storing of coal. No power plant should be designed without providing for the storage room for from 500 tons to 1,000 tons of coal, and in larger plants this capacity should be very much increased. The danger of a strike in the coal regions, or delay in transportation incident to strikes, weather, floods, etc., are so many and great that no power plant should take these risks, but should provide storage for sufficient coal on hand to provide against a contingency of this kind. The difficulties in designing a proper bin or pocket for storing this coal are many and great, owing to the large floor space required. Our attention has been called to a pocket lately designed by the Berlin Iron Bridge Co., of East Berlin, Conn., for the power house of the Steinway Electric Railroad Co., at Astoria, which has attracted much attention. This design is unique and possesses many points of merit, owing to the large amount of storage capacity in proportion to the exceedingly limited amount of floor space occupied. The general appearance is shown in the accompanying illustration, which is taken from a photograph of the completed pocket, in operation. Especial attention is called to the cylindrical form of construction. This particular pocket is 28 feet in diameter, 54 feet in height, and has a capacity of 1,000 tons of coal. The coal is unloaded from the barge or carts, at the side of the pocket in the ordinary way, and hoisted by means of a bucket to the top of the pocket, an ordinary hoisting engine being all that is necessary. There is an



COAL POCKET, STEINWAY, L. I., ELECTRIC RAILWAY.

opening in the side of the pocket, near the base, for removing the coal in the ordinary way, so that it can be carried into the boiler room by means of an endless chain, with buckets, or by hand, or by carts, or in whatever way may be desired. The advantage of this pocket does not lie in its presenting any additional facilities for handling coal, but more in its being an economical method of storing coal, and as such, it is claimed to have unusual capacity in proportion to the floor surface. The patents on this construction are owned and controlled by the Berlin Iron Bridge Co., of East Berlin, Conn.

A 103 MILE TROLLEY LINE FOR INDIANA.

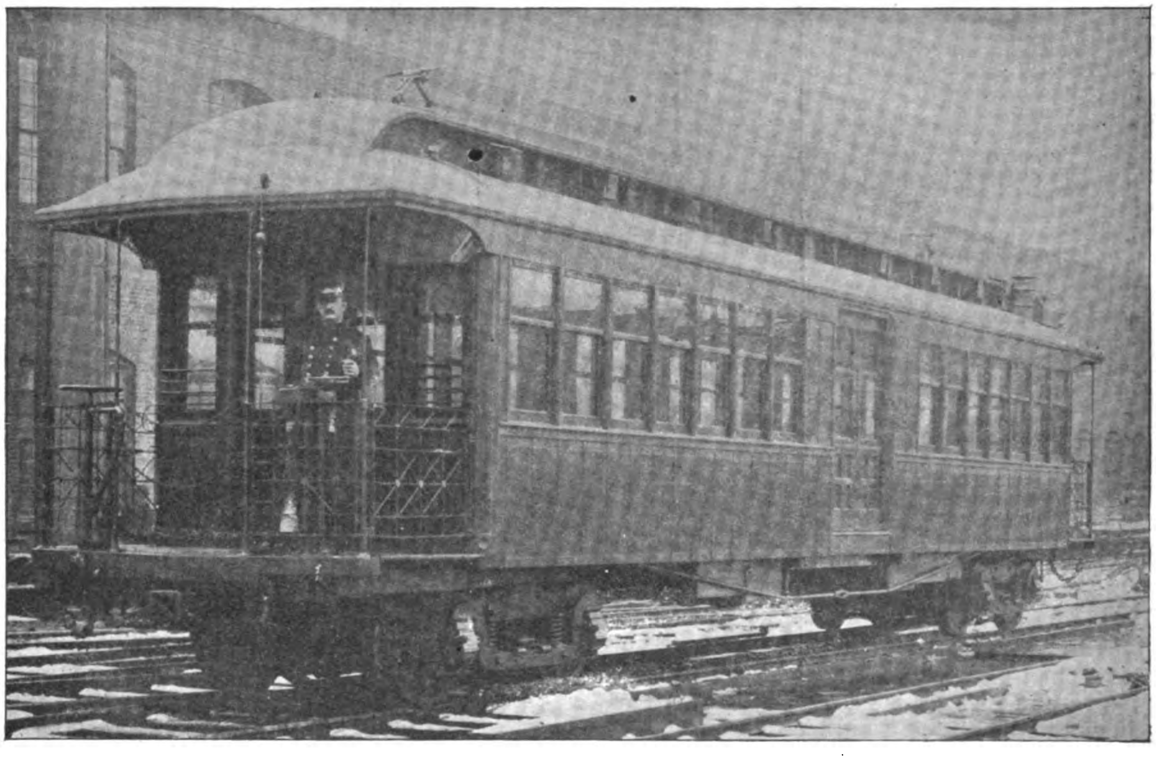
An electric line 103 miles in length is projected through northern Indiana, starting at Celina, Ohio. It is planned to build northwestwardly through Geneva, Montpelier, Warren, Lincolnville, Wabash, Roann, to Rochester. It is the intention of the builders a wealthy syndicate, to handle both freight and passengers at extremely low rates, and the line will be laid with 70-pound steel and finely equipped. Charles Everett, of Fort Wayne, representing the syndicate, last night met a large number of Wabash business men and said that a subsidy of $70,000 would be asked from this county. The capitalists will put a million and a half in the property, and it is hoped to have the road in operation in one year.

ELECTRIC MOTORS ON THE BROOKLYN BRIDGE.

THE first official test of electricity as applied to the switching of the cars on the Brooklyn Bridge was made Feb. 8. The motor car, equipped by the General Electric Company, was coupled to three of the ordinary passenger cars and the complete train of four cars was switched by the motors from the incoming to the outgoing platforms and thence to the cable sheaves several times. The car was then taken over the complete bridge circuit twice. Complete satisfaction was expressed by the president and by Chief Engineer C. C. Martin at the manner in which the work was performed.

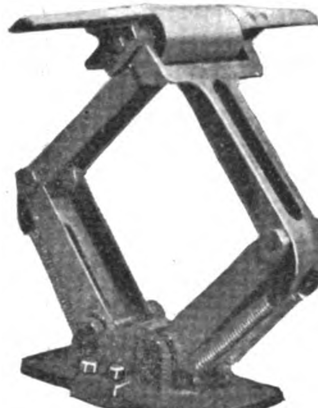
If the general plan adopted at first proves economical as well as satisfactory, a certain number of cars will be equipped with four motors, one on each axle. Each of these motor cars will remain with its own train at all times, switching it from the incoming to the outgoing tracks and pulling or pushing it over the tilting sheaves, when the grips will take up the cable and the motors cease work. Should the grips slip while the train is mounting the 3.78 per cent grade, the motors can come again into requisition and assist the trains over the summit. Moreover, during the early morning hours, when traffic has become light and the cable is no longer running the trains can be operated entirely by motor cars, as they now are by the locomotives. The eventual outcome will probably be the exclusive operation of the bridge railroad by these motor cars. Meanwhile, they will switch the trains, and as each train is equipped with its own switching power, the motor car, all the interference which the steam locomotives have hitherto placed in the way of the incoming and outgoing trains will be done away with and the complexity of the switching be greatly reduced. At present the time consumed in switching a train is twenty seconds, and in that time a large number of people gather on the platforms. With the new motor and the new principle of operation it is expected that passengers will at all times have cars waiting for them. Besides the gain in time in the switching operation, all the inconveniences of the locomotives—the noise, smoke, steam and gases—will be eliminated, and this in itself will be no small gain.

Car No. 76, one of the regular passenger cars of the Brooklyn bridge, has been selected to receive the first electrical equipment. All the apparatus, with the exception of the controlling handles and circuit-breakers, is placed out of sight beneath the floor of the car. The ordinary light Pullman trucks on which it has hitherto run and the cable grip mechanism have been removed. Heavier trucks were necessary to carry the motors. These were supplied by the McGuire Company, of Chicago, and combine the best features of the passenger and locomotive truck.



Electric Motor Car On The Brooklyn Bridge.

The general character of the motor equipment is similar to that in use on the Chicago Elevated and Nantasket Beach roads, above mentioned. The motors are of the G. E. 1200 type, exerting a horizontal effort of 1200 pounds when mounted on a 33-inch wheel. Four of these motors are employed, one to each axle, or two to each truck. They are completely incased and are water and dust tight. The armatures are of the well-known iron-clad type, the windings being sunk into slots in the armature core. The Eickemeyer winding is used



Trolley Arm On Brooklyn Bridge Motor Car.

on the armature; by this method the crossing of two wires of large difference of potential is avoided.

The ratio of reduction between the armature shaft pinion and the wheel gear is 3.5 to 1. Each motor weighs about 3,000 pounds. With this equipment and the regular train a speed of about fifteen miles an hour may be obtained. Each motor is suspended on the truck from two trunnions in the upper field set in two bars, the outer ends of the bar resting on elliptical springs. The axle is thus relieved of nearly all the weight of the motor. At the base of each motor, facing the ends of the car is a small roller which depresses the cable and allows it to pass the motor without injury, while a long iron bar runs beneath the truck and depresses the tilting sheaves, preventing them from striking the motor.

The operation of the motors is controlled by series parallel controllers of the L 4 type, which have given such general satisfaction on the Chicago roads.

The resistances as well as the magnetic cut-outs are also placed beneath the car floor. Beneath each hood of the car is an automatic circuit breaker, placed within easy reach of the motorman. The operation of this device is instantaneous and is an effectual safeguard against any accident to the motor. These circuit breakers take the place of the main circuit hood switches, but are wired in multiple with each other instead of in series. To guard against any possibility of one being closed while the motorman is at the other end of the car and desires to open his main circuit, only one handle is provided. The handle cannot be taken off without opening the circuit breaker, and when removed the circuit is locked open. As the motorman must take the controller and circuit breaker handles with him when changing ends, all danger of complication is avoided.

The car is equipped with twelve electric heaters, manufactured by the Consolidated Car Heating Company, of Albany, N. Y.

The collector which will take the current from the overhead wire is a diamond-shaped frame of metal set longitudinally upon the roof of the car and carrying at right angles a bar in the center of which is a roller. The arms are wide enough to preclude any possibility of missing contact. The diamond frame is depressable and expansible on the principle of the pantograph, allowing a play up and down to conform to the varying heights of the overhead wire. With this collector the trouble of reversing is entirely done away with.

The power to run the car will be taken from the overhead wire already in position, supplying current to the electric lights in the cars. The extra current, however, will be supplied from the Fulton street feeder of the Kent avenue station of the Brooklyn City Railway, the return wire being connected to the rails of the surface road.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED FEB. 4, 1896.

Accumulators:—

SECONDARY BATTERY. A. E. W. Boucher, Prilly, Switzerland 553,831. Filed Aug. 13, 1895.
The positive plate is gold or platinum.

ELECTRIC BATTERY. D. S. Williams and H. M. Hamrick, Philadelphia, Pa., 554,043. Filed May 15, 1895.
The combination with zinc electrode, of an electrode composed of a series of superposed perforated blocks of active material, plates of lead, similarly perforated, and interposed between the various blocks.

Alarms and Signals:

SUCCESSIVE NON-INTERFERENCE SIGNAL BOX. F. W. Cole, Newton, Mass., 553,838. Filed April 21, 1890.

NON-INTERFERENCE SIGNAL BOX. F. W. Cole, Newton, Mass., 553,839. Filed March 7, 1891.

SUCCESSIVE NON-INTERFERENCE SIGNAL BOX. F. W. Cole, Newton, Mass., 553,840. Filed May 3, 1890.

NON-INTERFERING SIGNAL APPARATUS. J. J. Ruddick, Richmond, Ind., 553,873. Filed June 28, 1890.
Details of construction.

ELECTRICAL WHISTLE CONTROLLING DEVICE. A. E. Colgate, New York, 553,900. Filed Nov. 24, 1890.

PRESSURE ALARM FOR GAS SUPPLY PIPES TO FURNACES. F. S. Baker, Chicago, Ill., 554,016. Filed July 22, 1895.

ELECTRICAL CIRCUIT CLOSER. L. B. Miller, Elizabeth, N. J., 554,074. Filed Aug. 3, 1895.
Details of a burglar alarm window spring.

APPARATUS FOR RAILWAY SIGNALING AND SWITCHING. J. D. Taylor, Chillicothe, Ohio, 554,097. Filed Oct. 21, 1894.
An improvement upon Letters Patent No. 516,903.

Batteries.

ELECTRIC BATTERY. C. J. Hirlimann, Fort Lee, N. J., 554,124. Filed Oct. 25, 1895.
The object is to provide a battery in which there is a large surface of the carbon element in a single cell.

Conductors, Conduits and Insulators:—

INSULATING JOINT. W. O. Duntley, St. Loius, Mo., 553,844. Filed March 25, 1895.

ELECTRIC CONDUCTOR AND CONTACT DEVICE THEREFOR. W. P. Allen, Chicago, Ill., 554,103. Filed July 15, 1895.
A shallow conduit arrangement with the conductor enclosed in a flexible metallic casing.

Distribution:—

ELECTRIC TRANSFORMER. W. K. Freeman, Ft. Wayne, Ind., 553,847. Filed July 5, 1895.
Relates to a novel form of transformer plate.

Dynamos and Motors:

COMMUTATOR FOR MAGNETO-ELECTRIC MACHINES. J. C. Henry, Westfield, N. J., 554,063. Filed Dec. 16, 1891.
A commutator for a magneto-electric machine having the radial arms of its alternate segments surrounded with insulation, and insulation applied to the alternate segments only.

Lamps and Appurtenances:—

ELECTRIC ARC LIGHTING. G. R. Lean, Cleveland, O., 553,919. Filed Sept. 26, 1895.
Similar to patent below.

ELECTRIC ARC LIGHTING SYSTEM. G. R. Lean, Cleveland, O., 553,920. Filed Sept. 27, 1895.
Similar to patent below.

ELECTRIC ARC LIGHTING. G. R. Lean, Cleveland, O., 553,921. Filed Sept. 27, 1895.
It is the object of this invention to provide means whereby two or more lamps, not in themselves adapted to burn in series, can be successfully operated in multiple arc series on high voltage constant potential circuits.

ELECTRICAL IGNITING DEVICE. W. Kaiser, Vienna, Austria-Hungary, 553,960. Filed Sept. 6, 1895.
A sparking igniting arrangement.

ELECTRIC CARRIAGE LAMP. P. H. Quinn, New York, 554,089. Filed Dec. 3, 1895.

Miscellaneous:—

APPARATUS FOR ELECTRIC WELDING. H. Lemp, Lynn, Mass., 553,923. Filed June 17, 1891.
The invention consists in applying to the metal heating electric currents of different frequency during the manipulation.

MECHANICAL AND ELECTRICAL DEVELOPMENT AND STORAGE OF WIND POWER. W. L. Negbaur, Brookline and J. J. Feely, Walpole, Mass., 554,138. Filed Oct. 9, 1895.
The improved device for the utilization of wind power herein described, consisting of a wind motor and a driving shaft operated thereby, a driven shaft provided with a device for storing energy substantially as described, and an intermissive clutch connection between the two shafts.

Railways and Appliances:

SPRING SUPPORTING EAR FOR TROLLEY WIRES. C. A. Lieb, New York, 553,858. Filed June 23, 1894.
As a new article of manufacture, a trolley-ear comprising a bolt portion adapted to secure the ear of the insulator, a body part, a sleeve adapted to secure the trolley wire in place and a slot in the body part between the sleeve and the bolt portion.

ELECTRIC TROLLEY. N. Muslar, West Boylston, Mass., 553,927. Filed April 9, 1894.
Details relating to trolley wheel construction.

ELECTRIC RAILWAY. F. C. Esmond, Brooklyn, N. Y., 553,978. Dec. 13, 1894.
Sections of the working circuit are switched in automatically by the car.

ELECTRIC RAILWAY. F. C. Esmond, Brooklyn, N. Y., 553,979. Filed April 19, 1893.
Similar to patent below.

ELECTRIC RAILWAY. F. C. Esmond, Brooklyn, N. Y., and H. F. Gray, Passaic, N. J., 553,980. Filed May 4, 1893.
Relates to a surface circuit closing device.

CIRCUIT CONTROLLING DEVICE FOR ELECTRIC RAILWAY SYSTEMS. F. C. Esmond, Brooklyn. N. Y., 553, 981. Filed July 1, 1893.
Relates to construction of surface contact switches.

UNDERGROUND SYSTEM FOR ELECTRIC RAILWAYS. W. P. Allen, Chicago, Ill., 554,102. Filed June 22, 1895.
Consists essentially of an inner metallic conductor, an outer metallic sheath normally disconnected from said conductor, and insulating supports at each end of said sheath, and an electrical connection through said sheath to said inner conductor.

UNDERGROUND SYSTEM FOR ELECTRIC RAILWAYS. W. P. Allen, Chicago, Ill., and A. S. Krotz, Springfield, O., 554,104. Filed Aug. 23, 1895.
The working conductor is placed in a flexible metallic casing.

Regulation:—

AUTOMATIC CURRENT REGULATOR. S. C. C. Currie, New York, 553,901. Filed Feb. 20, 1895'.
The combination with a circuit embracing a secondary battery, of a resistance device for controlling the amount of current passing through the circuit, and means comprising an expansion-rod for varying the resistance offered to the current.

REGULATING SOCKET FOR INCANDESCENT LAMPS. A. B. Hendricks, St. Mary's, Ill., 553,911. Filed June 19, 1895.
A revolving rheostat enclosed in the socket.

Switches, Cut-Outs and Etc:

ELECTRIC LIGHT SWITCH. H. W. Lawrence, Denver, Col., 553,857. Filed April 1, 1895.
A three way switch, by means of which one or more lights in a circuit may be lighted from one switch and extinguished from another located at a distant point.

FUSE BOX. J. S. Strouse, Baltimore, Md., 554,042. Filed Oct. 5, 1895.
In a fuse box having two fusible wires in electric circuits, a clamp for each wire combined with a single spring to place of tension on both clamps.

AUTOMATIC SWITCH. J. F. McElroy, Albany, N. Y., 554,080. Filed Jan. 2, 1892.
Intended for use in same inventor's train lighting system by battery charged from dynamo driven from the car axle.

FUSE HOLDER AND LIGHTNING ARRESTER. H. A. Lewis, Norristown, Pa., 554,130. Filed Jan. 17, 1895.
A binding post provided with a slot and a spring clamp having one member stationery relatively to the post, and a movable spring member extending into the slot of the post.

ELECTRIC SNAP-SWITCH. G. W. Hart, Hartford, Conn., 554,221. Filed Sept. 7, 1894.
Details of construction.

Telegraphs:

TELEGRAPHY. P. B. Delany, South Orange, N. J., 553,957. Filed July 25, 1891.
Comprehends the depletion or diminishing of each impulse of current entering the line at the transmitting station after a period of uniform duration of all impulses during which the full strength of the current has passed into the line sufficiently to actuate the receiving instrument.

TELEGRAPH KEY. W. Deats, Amawalk, N. Y., 554,112. Filed June 16, 1894.
In combination, a transmitting key lever, a rotary operating knob thereon, a circuit switch having one contact mounted upon the knob or knob spindle, and the other contact mounted on said lever.

Telephones:—

TELEPHONES. A. Dinsmore, Chicago, Ill., 553,843. Filed March 3, 1895.
Means for agitating the carbon when giving the call signal, so as to prevent packing.

REGISTERING APPARATUS FOR TELEPHONES. F. Quatram, Pankow, Germany, 553,964. Filed July 26, 1895.

ADJUSTING APPARATUS FOR TELEPHONE SIGNAL BELLS. C. F. Dunderdale, Chicago, Ill., 553,977. Filed June 27, 1895.

TELEPHONE APPARATUS. C. J. Schwarze, Adrian, Mich., 554,036. Filed Sept. 17, 1895.
The transmitting, receiving and signaling devices are all organically combined in a single instrument.

TELEPHONE SYSTEM. W. A. Houts, Parker, So. Dakota, 554,125. Filed Dec. 24, 1894.
A call box for automatic exchange telephone systems.

TELEPHONY. C. A. Randall, London, Eng., 554,141. Fied Dec. 31, 1894.
A granulated carbon transmitter, designed to avoid sparking.

MISCELLANEOUS.

RECENT IMPROVEMENTS IN AMERICA AND EUROPE IN THE STORAGE OF ELECTRICITY.[1]

BY HERBERT LLOYD.

DURING the ten or fifteen years that cover the period during which storage batteries have been more or less in commercial use, the electricians of this country have been divided into two distinct classes; and two only—those unalterably opposed to their use, and the other class firm believers, and, one might say, enthusiasts.

In Europe one gets the impression from an acquaintance with electrical engineers—in England, France and Germany, at any rate—that accumulators are considered an essential feature in almost all electrical work. Some engineers are greater advocates than others of the system, but all are apparently believers. When it is borne in mind that the discovery of secondary currents was made in 1801, and even a lead accumulator was made in 1803, it seems strange that it has only been within the last five or six years that a lead accumulator has been proved to be a commercial piece of apparatus.

A really practical storage battery was, of course, made by Planté in 1860, and another step was made in 1881, when Faure and Brush developed the battery plate made by the application of already formed active material. In about 1890 the Chloride plate was developed, differing both from the Brush-Faure and Planté. This plate depends for its usefulness on the peculiar and beautiful crystalline structure of the cast material. Although the present state of the art shows more than one excellent form of positive plate, there has nothing yet been produced comparable with a Chloride negative plate. Its capacity for weight and ability to withstand both the use and abuse which a battery, to be successful, must withstand, is almost phenomenal. In England and France the companies doing by far the greater portion of the business use no negative but a Chloride negative, and in those countries there are no fundamental battery patents in existence to-day.

In England one is impressed not perhaps with the magnitude of the battery installations, but by their number. Private house plants run by gas or gasoline engines are simply abundant. Central station batteries are being installed about as fast as central stations are built, which in England is comparatively slow. In Manchester, London and Belfast, Ireland, very large central station batteries have been installed within the past year.

Electric traction, of course, in England, and on the continent, is carried out on a very small scale, either trolley or battery traction. In Birmingham, England, a storage battery road has been in operation for some six or seven years, and has been the experimental ground for almost all makers of battery, and the service rendered was, of course ,not the most satisfactory. A little over a year ago the Chloride Syndicate got a contract for the equipment of all the cars of this line with their battery, and with the experience of their allied company in France at their back, they have been entirely successful, giving service satisfactory to the railroad company, and doing the business at a profit to themselves.

In France, the Madeleine and St. Denis Road has now been in operation over three years, running some thirty 22-foot cars, double decked, seating between 50 and 60 people. These cars have run up to this time between two and three million car miles, and the company have every prospect of gradually replacing the horsecars in Paris, in the face of the most terrific competition with steam motors, compressed air motors, gas motors, and I do not know how many more. On this road some very good results have been obtained in what they call "recuperation." A very careful test, covering 100 trips, about 11 miles each, gives the following results, according to figures given by M. Sarcia:

The car while descending a 10% grade could recover 57% of the energy expended in ascending it; on a 4% grade a return of 42% is effected, and on a 2% grade 23%. On a 1% grade the recuperation is zero, with a traction coefficient equivalent to 22 pounds per ton. If the traction coefficient could be reduced to 11 pounds per ton, there would be recovered, in utilizable form, according to their experience, 63% of the energy expended in ascending a 10% grade, and with that low coefficient of traction 23% could be recovered down a 1% grade. If the traction coefficient was zero on the level, the car having no dead resistance, either electrical or mechanical, there would be recoverable on descending a 2% grade 70% of useful energy, the efficiency of the battery being in this case 70%. An electric mountain railroad recently built on the Isle of Man, on which the grade is almost a uniform 12%, is equipped with a trolley system having a battery in the power house. On this road the car descending the grade delivers back to the battery over the line about 33% of the energy which it consumes in ascending, so that it is beyond question that these applications should be taken advantage of wherever it is possible, the economy being so apparent.

The cars that have been in operation on the Paris roads for three years are of the old type, with the batteries placed under the seats, but new cars are being equipped with one box of batteries suspended under the car, thus eliminating the many disagreeable features incident to locating the batteries under the seats. The practice heretofore has been to run 33 miles on one charge with a battery weighing about three tons. With the newer cars the battery weighs about one and one-half tons and runs one 11-mile trip on a charge, although under good conditions it would be capable of two such trips. In the new cars no mechanical brake is used at all, the braking being accomplished by the charging of the battery, although for the final stop the motor armatures are short-circuited. The motors are shunt wound, always used in multiple, and in starting, resistance is inserted in the armature circuits, which is gradually removed to increase the speed until it is all out. To attain full speed, the field is weakened by inserting resistance.

The matter of charging the batteries on this road has received very careful attention, and has been modified at various times. Originally, when the road was started, the battery was charged at a constant potential, 108 cells being thrown on to a 260-volt bus. Under these conditions the charging current commenced about 150 amperes, but gradually decreased, so that at the end of charge it has reached about 10 amperes. They now use two busses. The battery is thrown on to a bus equivalent to 2.4 volts per cell, where it is left for three hours, or until the current has fallen from 90 to about 30 amperes. At the end of the third hour the battery is thrown on a higher bus, equivalent to 2.55 volts per cell, on which the charge is completed in from one to two hours, or more, thus avoiding the use of resistance.

The most interesting feature in connection with the operation of this road is the method of re-pasting the positive plates. The positive support plate is grooved and made of an alloy, upon which there is very little electrolytic action, and by a special process the peroxide which has been deposited on the bottom of the jars in a worn-out cell is re-pasted into these grooves. Two men are employed re-pasting and are able to keep some thirty cars in continuous service, so that the cost of this portion of the operation is wonderfully small. I saw a number of these grids which had run between 25,000 and 50,000 miles, showing no evidence whatever of depreciation. The casting of these grids is carried on by a special process, by which the alloy is cast under very heavy air pressure, which method is protected by an original American patent, the French patents of which have been assigned to the French Chloride Company.

The Sector Clichy, a five-wire station at Paris, has two very large batteries installed last fall, one-half being manufactured by the Chloride Company, the other half by the Tudor Company. This battery, which is now complete, is probably one of the largest in the world.

In Germany the Tudor Company, with works at Hagen, have during the past eight years installed over 5,000 plants.

A most interesting application of storage battery has just been made by them on the street railroad of Hanover, where the cars are propelled by storage batteries within the city limits, and run by the trolley outside, the battery being charged without removal while the cars are running through the outskirts. Forty-four cars have been installed on this plan. Battery cars are also running in Berlin, Hagen and other German cities, and also in Vienna. Up to the past year the German Tudor Company has devoted its attention almost entirely to lighting work, but in Germany and France there is a feeling that the time is ripe for the development of storage battery traction, and within the next year a great deal will be accomplished in this line.

It is well known that in this country patent litigation has long interfered with the development of the storage battery business. Something over a year ago one strong company acquired all the patent rights of the contending companies, thus removing all question on the score of patents. This company being also allied with the three strongest European companies is able to take advantage of every improvement that is made either here or abroad, and can therefore produce the best battery obtainable.

[1] Read before the New York Electrical Society, Jan. 29, 1896.

Some months ago the New York & Harlem River R. R. Company, of New York, decided to place two storage battery cars on its Madison avenue line, to be operated through the Winter, in order to determine whether or not the system has been brought to a stage of advancement which would warrant the equipment of the entire road.

In the cars run from Eighty-fifth street to One Hundred and Thirty-fifth street the batteries are suspended between the axles, on the car truck, entirely independent of the car body. In fact, so independent are the trucks that thew have been run alone, without any car body on them at all. The cars have standard Stephenson bodies 10 feet long and standard Peckham trucks.

Sixty cells of nine-plate traction type Chloride accumulators, capacity 400 ampere hours, are placed in a tray about 4½ feet square and connected up solidly by lead burning, in two series, of thirty cells each. This tray is placed on a small transfer truck, running on a narrow-gauge track in a pit 8 feet below the level of the street car tracks. An electric elevator is utilized to hoist the tray full of batteries, together with transfer truck, up between the street car rails into position on the street car truck, where the tray is automatically locked and the elevator, with transfer car, withdrawn. Large contact shoes on the car, kept in place by steel springs, engage with contact plates on the trays, as batteries are raised, so that the connections are made automatically.

Each car is equipped with two G. E. 800 motors, supported outside of the axles, and two "K" controllers. A cable system will be applied to the shifting of the transfer cars in the battery pit.

The special advantages of this particular method of battery application include the features before mentioned, of low steps for cars and the standard height and width of seats; an entire independence of car body permitting of a change, as, for instance, from open to closed car bodies, and vice versa; together with an entire absence in the car of odor from the battery electrolyte; a compact, easily handled tray of batteries; utilization of space below and above the street car floor, without occupying one square foot of the car shed proper.

In the past batteries were made of a practically uniform type of small size, capacity being obtained by putting many series of cells in multiple. Now large units in batteries have come into use, just as large generating units have, an example of this being the battery installed in the Boston Edison Company's station, where each cell weighs about three tons, capacity 8,000 A. H., or 16,000 A. H. at 140 volts, with a maximum output of 8,000 amperes.

The size of cell should be increased almost indefinitely. Batteries are now constructed specially to suit the work for which they are intended. Until recently in isolated plants, such as private houses, 150 ampere-hour cells in glass jars were generally used, as many as eight of such series being installed in one house. A private house plant has been recently installed in this city, with one series of cells of 2,500 ampere-hours each, and in the last three months half a dozen similar plants have been installed, varying in size from 1,000 ampere-hours up.

Within the last year the question of electric train lighting has come up with considerable force, and cars are now running between New York and Chicago lighted by storage batteries alone, without any systems for operating dynamos and engines on the train. Train lighting in this country is a different matter from train lighting in Europe. In Europe a few 8-candle power lamps to the car are considered sufficient. The cars just referred to as running between New York and Chicago have 44 16-candle power lamps. A train consisting of five or six such cars requires a lighting plant of quite serious proportions.

Experiments are being made with more or less success with small dynamos driven from the axle of the car; a moderate-sized storage battery is used to maintain the lights when the speed of the train falls below some 20 miles an hour. A car so lighted is now running satisfactorily between New York and Washington.

Perhaps the application of storage batteries which will arouse greatest interest is that of stationary batteries applied to equalizing the load on trolley lines. Two or three plants of this character have been installed within the past year. In a road of considerable length, the application of a storage battery would save in feeder copper a great deal more than its own first cost, and the contingent advantages to be derived from the operating of the generating plant at a practically constant load are too well known to require reiteration.

The application of batteries to electric elevator installations shows as great or even greater advantages. As Mr. Sprague stated in his paper before the last meeting of the American Institute of Electrical Engineers, to operate six elevators without a battery would require a 120-kilowatt generating plant, while the average load would be but 35 to 40 per cent. of this. With a properly constructed battery, he states that the direct plant could be reduced to 60 kilowatts, or even to 50. A battery was installed last Fall in connection with the elevator plant in the new court house at Minneapolis, and the curves shown prove the effect. A similar plant is just being installed in the Chicago Board of Trade Building for the same purpose.

In this class of work, it is necessary that the battery should be capable of discharging at rates which would completely exhaust it in from half an hour to an hour. These discharges, of course, are not long continued, and the batteries as now constructed are not injured by this treatment. Up to two or three years ago a 10-hour rate of discharge was considered a maximum rate. Recent improvements in the manufacture of storage batteries have been entirely along the line of producing a battery which is capable of discharging in from one to three hours, although the cost has not materially decreased, if capacity alone is considered; but when discharge rate is considered, the cost has been greatly reduced, since a battery which can be discharged at five times its normal rate will replace one five times its size of the old type.

One feature of the battery business which has received a good deal of attention recently is the specific gravity of the electrolyte. The curves shown are very interesting, as they show how the capacity of a cell varies with the density of the electrolyte; the plates being respectively ¼ inch thick and 4-10 inch thick. The thicker plate has a maximum capacity when the density of the acid is about 1.275; the ¼-inch plate has a maximum capacity when the electrolyte is about 1.240. It is very noticeable how rapidly the capacity falls off on either side the maximum point. These curves are taken from two Chloride cells, the volume of the electrolyte being sufficient to prevent any great change in specific gravity. The mean volts on discharge shown in the upper curves rise almost regularly as the acid density rises.

The rate of discharge being the same per pound of active material, the discharge rate per superficial area is therefore approximately 40% greater with the thick plate than with the thin.

The battery just being installed in the new Edison Station at Twelfth street, New York, consists of 150 4,000 ampere-hour cells. The positive plates of this battery somewhat resemble the "Tudor" type, the negatives are the "Chloride" type. They are installed 75 cells on each side of the three-wire system; the 25 end cells on each side are used as regulating cells, being connected by copper bar to four regulating switches, two on each side, so that the battery can be discharged at different potentials. The battery has a capacity at 10 hour rate of 4,000 ampere-hours on each side, at a 3-hour rate of 3,000 ampere hours on each side, and at one hour rate of 2,000 ampere hours on each side.

The erection of the battery in two tiers, the upper tier of iron frame work, is perhaps new in this country. The insulation of the cells is effected by a special type of oil insulator, which makes this method of erection quite safe. The battery is installed in a room approximately 20 feet by 40 feet, which is, I think, the smallest space in which a battery of equal capacity has yet been placed.

Another Edison Station recently equipped is in Lawrence, Mass., where a smaller battery, with capacity of about 1,500 ampere hours is in use; this battery is discharged completely in two hours between four and six in the afternoon, during the peak of the load.

The Motocycle contest in Chicago has attracted a good deal of attention to the question of electric road wagons. The carriage which secured the gold medal, first prize, was built by Caffrey, of Philadelphia, and weighed complete 1,650 pounds, including a battery weighing 664 pounds. The battery consisted of 44 50-ampere hour Chloride cells; the wagon was equipped with two 1½ h. p. Lundell motors, with series parallel controller.

This carriage is capable of running from 25 to 30 miles on one charge at a speed of 10 miles an hour; it could attain a maximum speed of about 20 miles an hour for one hour, carrying four people. The two front wheels of the carriage are driving wheels and it is steered by the rear wheels. On the first speed with an average discharge of 5.6 amperes or two-thirds of an electrical h. p., a speed of 4.6 miles was attained, and at this speed the carriage would travel 46 miles on one charge. On the second speed, running at 10 miles an hour, it required 13.2 amperes or 1 56-100 h. p., covering by this speed about 30 miles on one charge.

This carriage has been sold and shipped to Germany to be used as a model for building similar ones over there.

This question of electric vehicles is attracting the atten-

tion of the large carriage and bicycle manufacturers, many of whom are building such vehicles, and with a battery such as is now produced capable of very heavy discharges, and with good roads, it would appear as though the business would soon assume large proportions.

The use of electric launches is growing steadily, but not as rapidly as other applications. In this work light weight is not so important as for carriage work, but batteries for this work must have large capacity, as it is often necessary to make long runs before facilities for re-charging can be obtained.

The improvement in storage cells for this work is shown in the fact that the batteries on the launches which ran for three months at the Atlanta Exposition did not cost one cent for repairs, which was not the case with those used at Chicago, at the World's Fair. The battery used at Atlanta was the Chloride type.

NEWS AND NOTES.

AN ELECTRICWAY BILL FOR GOVERNMENT LANDS.

It may not be generally known that the mountains and mountainous regions of the West are withheld by the Government from homestead entry, and are set aside as Forest Reserves or mountain parks. As these regions are usually supplied with large water powers or mountain streams, furnishing water at great heights, it is therefore much to be desired that the National Government should do all within its power for the reasonable encouragement of enterprises seeking to develop these water powers for the generation of electricity and its transmission to towns or cities, whether they be near or far.

The matter has been brought before Congress, and on Jan. 10 the House Committee on Public Lands reported favorably Representative Bowers', of California, bill to amend the act approved March 3, 1891, granting a right of way upon public lands for reservoir and canal purposes by adding thereto the following:

"Section 2 That the Secretary of the Interior be, and hereby is, authorized and empowered under general regulations to be fixed by him, to permit the use of right of way to the extent of 25 feet, together with the use of necessary ground, not exceeding forty acres, upon public lands and forest reservations of the United States, by any citizen or association of citizens of the United States for the purpose of generating, manufacturing or distributing electric power."

In California and elsewhere small towns and cities located in valleys can utilize electric light and power at a minimum cost if allowed the right of way across Government lands in the foothills of the mountains, as this bill permits. Secretary Hoke Smith says:

"I see no objection to the amendment suggested by the Commissioner, providing that right of way through forest reservations may be authorized under regulations to be adopted by the Secretary relative to the use of grounds for the purpose of generating and distributing electric power."

The bill when passed will be far reaching in its effect, for it will at once add to an electric power corporation assets of the very highest real estate value, and of a class such as but few electric companies of any kind possess, an absolute and wide right of way—in short, an electricway—with unquestioned title and patent from the Government. The effect and advantage of this feature in promoting the organization of such companies will doubtless be very great, as it will afford investors a real estate and property franchise whose value will not be solely one of future possibilities, as is usually the rule with other franchises.

SEEING WITHOUT LIGHT.

Under date of Feb. 10 the following cablegram has been received by the daily press from London:

"A most remarkable discovery has been made, according to a dispatch from Rome, in connection with the investigation of Professor Röntgen's new force in photography. Professor Salvioni, of Perugia, read a paper before the Rome Medical Academy on Saturday, in which he describes an optical instrument of his invention which enables the human eye, by means of the Röntgen rays, to see through anything which those rays can penetrate. It is said that Professor Salvioni produced his wonderful invention, and by its means physicians present were enabled to see the contents of a closed aluminum box.

"Unfortunately no explanation is given of the means used to make the hitherto invisible rays, perceptible by man's optic nerve.

"A London photographer has found that a convenient substitute for Crooke's tube is an ordinary incandescent electric lamp, in which the filament has been broken. This improvised Crookes tube and an ordinary house to house electric light current will enable any photographer to make Röntgen photographs on a small scale."

"RAYGRAPHS" OF THE KIDNEYS.

A special dispatch of January 29 from Vienna says: "Dr. Neusser, professor of medicine in the Vienna University, showed this afternoon, by means of photographs taken by Roentgen's newly discovered system, the presence and position of calcareous deposits in the liver and kidneys of a subject."

LEGAL NOTES.

MOTION TO ADVANCE THE BERLINER CASE.

A motion was made in the Supreme Court of the United States on Feb. 3 by Attorney-General Harmon, as special counsel for the United States, to advance the Berliner telephone patent case for an early argument in next term of the court, and Messrs. Fish and Storrow said they would not oppose it. The brief in support of the motion sets out that the suit is brought to obtain the repeal of the patent granted to the American Bell Telephone Company, as assignee of Emil Berliner, the alleged inventor, on the ground that the application for it filed in 1877 was not issued until 1891, it being unnecessarily delayed in the Patent Office, the assignee promoting said delay for his own interests and in fraud of the rights of the public, and in violation of his duty to the public; that said Berliner patent practically controls the art of telephony, and having been thus delayed until 1891 (the patent of Alexander Graham Bell for the speaking telephone expiring in 1893), operates to prolong the control of the art of telephony for fifteen years beyond the time when, by the expiration of the said Bell patent, such control should rightfully cease; that said patent was granted by the Commissioner of Patents without authority of law, being for the same invention for which patent had been granted to the same applicant in November, 1880.

"If the United States," the brief says, "is right in its contention that the Berliner patent, for the reason stated, ought to be repealed, it is of great importance to the public and the repeal should not be unnecessarily delayed."

PERSONAL.

KORNETZKE—RACH.

By an order of the Court on January 18th, the name of Mr. Gustav A. Kornetzke, of Schenectady, N. Y., was changed to that of Christian G. Rach. Having been connected with the Edison underground tube work since its inception in 1880, Mr. Kornetzke is well known, and a general favorite among the managers and electrical staff of most of the Edison stations throughout the country. Mr. Kornetzke is now the manager of the Underground Tube Department of the General Electric Company, at Schenectady.

MR. JAMES MENZIES has succeeded Mr. J. E. Torbert as general manager of the Mexican Telephone Company. Mr. Menzies was assistant superintendent of the central division of the New England Telegraph and Telephone Company. Early in January he was released by the New England to the Mexican company.

MR. H. J. ODELL has resigned as general manager of the Concord (N. H.) Land and Power Company.

MR. C. D. WARNER has severed his active connection with the Standard Electric Time Company of Waterbury, and is succeeded by J. O. Lyman as superintendent.

SOCIETY AND CLUB NOTES.

CHICAGO ELECTRICAL ASSOCIATION.

The meeting of the above association, to be held on Friday, Feb. 21, at 1737 Monadnock Building, will hear a paper by B. S. Summers, chemist for the Western Electric Company, on the "Outlook for Electro Chemistry."

AM. INST. ELEC. ENGINEERS.

It is proposed to incorporate the Institute, which has now been in existence since 1884, and which has reached a membership of 1,000. Notice duly given by a majority of the council has been issued for a regular meeting, to be held in this city on Feb. 26 to consider the proposition to incorporate under section 5 of the membership corporations law of this State.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE NEW RUSHMORE ARC PROJECTORS.

THE RUSHMORE DYNAMO WORKS, who have for years manufactured searchlights and electrical apparatus for marine use, have in the last year brought out a complete line of high-power-lens mirror projectors, or searchlights, for commercial marine and naval use.

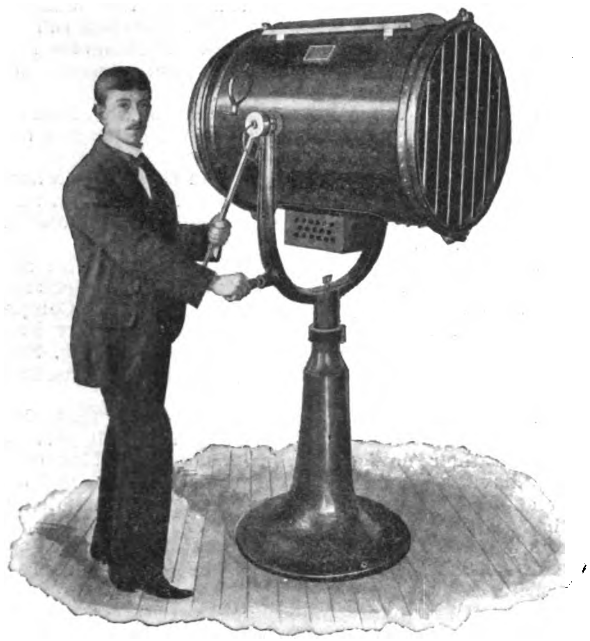


FIG. 1.—RUSHMORE ARC PROJECTOR.

In the common so-called searchlights there is an ordinary locomotive headlight reflector fitted with an arc light in place of the oil wick. This reflector absorbs nearly all the light and cannot be built for high power, as it soon rusts away.

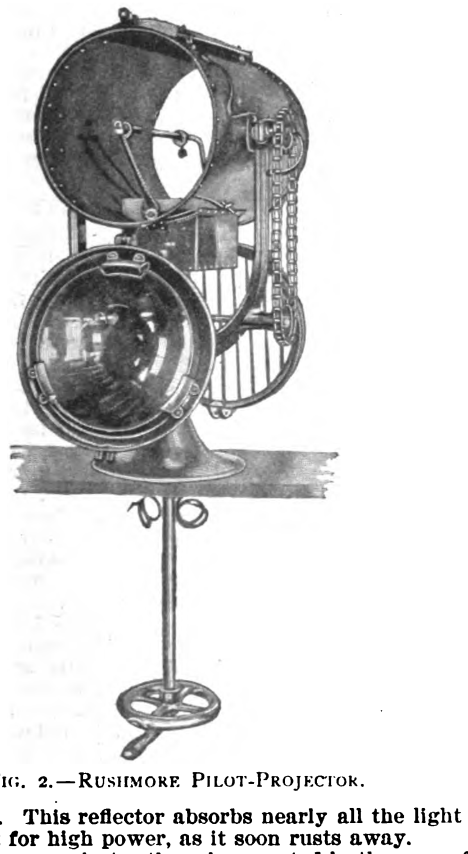

FIG. 2.—RUSHMORE PILOT-PROJECTOR.

In the Rushmore projector there is mounted in the rear of the cylinder, as shown in Fig. 2, a large silvered lens, and a special focusing lamp lies in a case in the bottom of the cylinder, which is entirely empty, except for the slender carbon holders, which cast no shadow, and the carbons are so placed that all the light generated is thrown directly upon the mirror and is projected forward in a perfectly straight beam. This arrangement permits the use of a powerful current in the arc without risk of heating, and by recent tests it has been shown that the projected beam has a power of over 1,000,000 candles per ampere in the arc.

Fig. 1 shows the plain projector as used in the Navy and on large lake and ocean steamers. Fig. 2 shows the pilot-house light fitted with the new controlling attachment for operating from within the pilot house. This is the small pilot-house light with front and back door open, showing the lens and lamp, from which it will be seen that it is easily cleaned and supplied with new carbons.

Fig. 3 shows the new Rushmore aplanatic lens with reversed image. This new lens has the remarkable property that by a slight movement it causes the beam to be spread over a wide area, thus dispensing with the heavy and costly diverging lenses used in the Navy.

Another type of this projector is fitted with a small motor in the base, so that the light may be placed at any point on the ship and the beam thrown in any direction by means of a small electric controller in the pilot house, thus doing away with all mechanical connections.

This apparatus is designed for the roughest commercial use, and is free from all complications. Quite a number of these projectors are already in use and giving entire satisfaction.

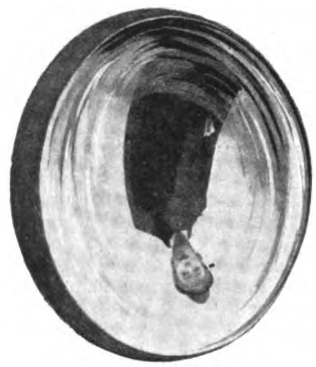

FIG. 3.

The Rushmore works have a complete lens-making plant, with which they have reduced the cost of lenses and made the cost of the best projectors but little more than the old-style headlights.

HOGAN BOILERS IN THE SEA CLIFF, L. I., STATION.

The Franklin Electric Illuminating Company, Sea Cliff, N. Y., which is considered to be one of the best equipped lighting stations on Long Island, is using the Hogan water tube boiler. The plant was started up in June, 1895, and ran continuously to Dec. 13, 1895, when the fires were drawn and the boiler examined. The report of the examination reads in part as follows: "The manhole covers of steam and distributing drums were removed, and the boiler was found perfectly clean throughout, not a particle of scale or deposit being visible. The same copper gaskets forming joints of manhole were used again and the joints were perfectly tight at 125 pounds pressure when steam was raised." This station lights the towns of Sea Cliff and Glen Cove, and careful investigation shows that the coal expenses per day of fifteen hours with the Hogan boiler is $2.50. The Hogan company have secured a contract from J. B. McDonald, contractor for the Jerome Park reservoir for a 500-horse power boiler at Fordham, N. Y., and have also recently installed boilers in the Lehigh Valley silk mills, at South Bethlehem, Pa.

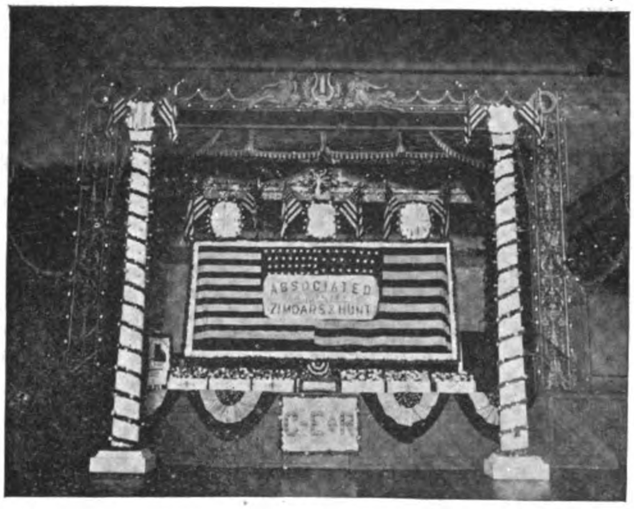
CUTTER'S HANDY WIRING TABLE.

Mr. George Cutter, The Rookery, Chicago, has issued a very neat and useful little pocket pamphlet as above, containing definitions, resistances, carrying capacities, voltage drop and incandescent wiring tables. Its cost is only 25 cents. The cover is paper, cloth stiffened.

MR. MYRON KNAPP, of Chicago, has been in the East for the past week or two, in the interests of his new company, the Graphite Rheostat Co. Mr. Knapp reports that this concern have made a distinct success of their apparatus and are as busy as possible filling orders. Several new agencies have been appointed in the East, and Mr. Knapp's many friends are wishing him the best of success.

DECORATIONS AT THE ZIMDARS AND HUNT ANNUAL BALL.

On the night of the 16th of December, the employees of the firm of Zimdars & Hunt, the well-known firm of electrical engineers and contractors, held their second annual ball in the Central Opera House in New York. The ball was a huge success in every way, and was of interest to electricians on account of the magnificent electrical display and decorations, which had been specially arranged by the employees,



ELECTRICAL DECORATION, ZIMDARS & HUNT.

who all helped after working hours to make the exhibit as complete as possible. Our illustration shows the large decoration at the end of the hall, which was the masterpiece of the occasion, and which was literally covered by large numbers of different colored lamps, controlled by switches, so that any desired effect of coloring and grouping could be produced at the will of the operator. In the lower left hand corner may be noticed a faithful portrait of a black cat, popularly supposed to be the mascot of the Zimdars & Hunt Co.

THE BALL & WOOD CO.

Among the New Year changes in business which will interest engine men we learn that Mr. F. H. Ball has sold his interest and retired from active participation in the management of the Ball & Wood Co., of Elizabeth. Br. Ball has been one of the officers of this company for a number of years, and desires to take up actively the profession of consulting engineer and mechanical expert, in which capacity he will still be connected with the company. His son, Mr. Bert C. Ball, also remains at the head of the draughting department.

The business of the Ball & Wood Company has been excellent during the past year, and has extended largely through the West since its Chicago office was opened a year ago. At present its shops are very busy executing the contract for a number of large engines for the Edison Electric Illuminating Company, of Paterson, and also orders for the New York and Brooklyn Bridge, Johnston Building, New York, Ellicott Square Building, Buffalo; St. Charles Hotel, New Orleans, and others.

ELEVATOR WANTED AT SPRINGFIELD, MO.

The Treasury Department, through the office of the Supervising Architect, is inviting proposals until Feb. 27, for all the labor and materials, and erecting complete, either a hydraulic or an electric passenger elevator, including pumps, tanks, piping, car, etc., for the United States Court House and Post Office building at Springfield, Mo. Prospective bidders may obtain additional particulars by addressing Hon. Wm. Martin Aiken, Supervising Architect, Treasury Department, Washington, D. C.

BERLIN IRON BRIDGE CO.

The Berlin Iron Bridge Company, of East Berlin, Conn., have just completed a very successful year. The shipments have been the largest in the history of the company and represented over one and one-half million dollars' worth of business. At the annual meeting of the stockholders, which was held at the office of the company on Thursday, Jan. 30, the following directors were elected. Chas. M. Jarvis, Burr K. Field, Geo. H. Sage, H. H. Peck of Waterbury, S. H. Wilcox of Brooklyn, N. Y., J. W. Burr and F. L. Wilcox. At the meeting of the directors the following officers were elected: President and chief engineer, Chas. M. Jarvis; vice president, B. K. Field; secretary, Geo. H. Sage; treasurer, F. L. Wilcox; manager of highway bridge department, D. E. Bradley; assistant to the president, E. W. Stearns.

WESTERN NOTES.

The Farr Telegraph and Construction Company of 342 Dearborn street, Chicago, are putting themselves in shape to furnish all telephone companies throughout the country with magneto bells, extension bells, receivers, induction coils and all telephone supplies at wholesale prices. Their motto is "quick sales and small profits." They will be glad to receive applications for their catalogue.

Mr. William H. McKinlock, president of the Metropolitan Electric Company, is in the East looking after the interests of the company.

The Wisconsin Electrical Construction Company, Milwaukee, report a nice business in general electrical supplies, and they also carry a fine stock of the newest designs of gas and electric fixtures in their extensive show rooms.

The People's Electric Company of Madison, Wis., a newly organized company, are selling agents for the electrical machinery manufactured by the Northern Electrical Company of Madison, Wis., Paiste specialties, Bryant & Hart switches, Grimshaw and Raven Core wires, Columbia lamps, Standard telephones, Badger electric railway goods, and general electrical specialties.

The Metropolitan Electric Company report that they are still receiving letters of congratulation from all parts of the country on their new mammoth catalogue. This catalogue seems to have taken the electrical trade by storm, and one and all pronounce it the largest and most complete catalogue that they had the pleasure of receiving. This company report the business outlook for '96 to be very encouraging.

The Standard Boiler Company of Chicago report a good business during the past year. They have moved into their new offices, 1120-21 Marquette Building. These boilers are built by the Link-Belt Machinery Company of Chicago, who have put in new and improved machinery for their manufacture, reducing the prime cost as well as making the various parts interchangeable. During the past year a number of fine plants have been installed, amongst others being 4,000 H. P. for the North Chicago Street Railroad Company at their new power station at Hawthorn avenue; 500 H. P. for the Cincinnati Edison Company; 600 H. P. for the Western Electric Company at their factory in Chicago, and various others. They report prospects for the coming year as good.

The Forest City Electric Company is a new Cleveland corporation. The purpose is to make and deal in all kinds of electrical machinery and apparatus. The capital stock is $25,000 and the incorporators are William B. Cleveland, Robert N. Lowe, F. H. Neff, W. H. Wherry and Walter G. Cleveland.

NEW ENGLAND NOTES.

The Pope Manufacturing Company of Hartford present the eleventh edition of their calendar pads in a form somewhat improved over that of preceding years. There are the usual quotations from Columbia users, but they take up less room than formerly, giving more space to the memorandum part of the pad. The illustrations take the form of vignettes, and are more numerous than in former years. A new feature with this year's calendar, and one which will readily find favor with those who ride bicycles, is the addition of information as to the moon's phases, so that engagements may be made as far as a month ahead for full-moon riding. We understand that these calendars may be procured, as usual, on the remittance of five 2-cent stamps.

The Graham Equipment Company of Boston have mailed to their friends one of the large-sized postal cards for which they are famous. The reverse of the postal contains a half-tone cut of the steel-frame car made by this company, while below is a very compact calendar of the entire year.

The Samson Cordage Works have issued a very pretty calendar, illustrating the destruction by Samson of his friend, the lion, while just below is a line advertising their spot cord.

Randolph, Mass.—The Randolph Electric Light Company, Randolph, Mass., are increasing their steam plant by the addition of a 160 H. P. tandem compound condensing engine from the Ball Engine Company of Erie, Pa.

NEW YORK NOTES.

Adams, N. Y.—The Adams electric light plant has been bought by Mr. R. F. Steele.

The Standard Air-Brake Company have found it necessary to remove to more commodious quarters, and are now located in the American Surety Building, 100 Broadway, New York.

THE ELECTRIC APPLIANCE COMPANY have just prepared a special catalogue of the "Paiste" specialties, listing a complete line of Xntric switches, Paiste sockets, cutouts, etc., together with a special net price list on same. They will be glad to send this catalogue on application. It makes quite a valuable list for reference, as considerable of the material has not been previously catalogued.

NEW YORK NOTES.

THE NIAGARA ELECTRIC CHEMICAL COMPANY has been incorporated with the Secretary of State to manufacture chemicals and chemical products. The capital is $100,000. Directors: Hamilton Y. Castner, of London, Eng.; Jacob Hasslacher, of New York City; Franz Roessler, of Perth Amboy, N. J., and William A. Haman, of Mount Vernon. The company will rent its power at Niagara, and is negotiating for a factory site. At present its manufactures will be confined to sodium and peroxide of sodium. The temporary office is at 73 Pine street, New York.

THE BAECHTOLD & PARKER ELECTRIC CO., 79 Washington Street, Brooklyn, have established, in connection with their electric light business, a department for the manufacture of a full line of standard types of street car commutators, which they are prepared to furnish in quantities. The previous extensive experience of the members of this company gives them an acquaintance with the peculiarities of all makes of railway armatures and commutators, and thus qualifies them for prompt and accurate work. The facilities for manufacturing have been improved, and in addition to general repair work, the company is prepared to take care of special work.

MR. M. R. RODRIGUES, 19 Whipple Street, Brooklyn, maker of "Premier" products, has recently added a Bliss power press to the other tools in his shop.

R. B. COREY & CO., of New York, have recently sold, through Messrs. E. H. Foerst & Co., of San Francisco, 325 Bergmann ornamental arc lamps for use in the Parrott Building, that city. Messrs. Foerst have also ordered for this building 7,000 Columbia incandescent lamps, and switchboard and panels of special design, by Bergmann & Co., of New York.

THE STANDARD PAINT CO., of New York, have just made an interesting shipment of their well known goods, P. and B. armature varnish and tape, for use on the new electric railway at Cape Town, Africa, which is already using considerable quantities of P. and B. goods. They have already made large shipments of their products to mining companies for electric plants in Matabele Land, and not a little of their special P. and B. paint for preservative purposes is now being used by various companies in Delagoa Bay. What further proof is necessary of the excellent qualities of P. and B., and the energetic management of the Standard Paint Company?

MR. GEORGE F. CHISM, formerly with the Standard Engineering Company, of Albany, N. Y., is now with Mr. Le-Grand Brown, of Rochester, N. Y. Mr. Brown is making a specialty of electric railway work, and Mr. Chism will direct his attention to the power plant department.

MR. W. H. McKINLOCK, President of the Metropolitan Electric Company, Chicago, is still in the East, and has closed some good business for his company.

THE PINKNEY-TOOMEY ELECTRICAL COMPANY has been formed in Jersey City, to make electrical instruments, supplies, etc. A. J. Booth is president. T. Sullivan, first Vice-President; J. Nolan, second Vice-President; F. Pinkney, Treasurer; J. Toomey, Secretary; R. Ingraham, Manager.

THE BIRDSALL ELECTRIC MANUFACTURING COMPANY, of New Rochelle, N. Y., has been formed, with a capital stock of $10,000, by Theodore Birdsall, of that place, and S. K. Johnson and Bryce Marr, of New York City.

THE FACTORY of Robert Edwards & Co., makers of electrical goods in north New York, was badly damaged by fire last week, the loss being put at $25,000, with insurance for $15,000.

THE FLEMING-SPENCE COMPANY, of this city, have made the H. N. Bates Machine Company of Boston their New England agents for their new and successful alternating arc lamp. The Fleming-Spence Company have some excellent reports on the working of their lamps on low frequency currents, as well as on high.

"We prize every copy highly, and cannot afford to lose an issue of so valuable a paper."—Clark Bros., electrical contractors, Berkeley, Cal.

THE VITRIFIED TERRA COTTA CONDUIT.

One of the exhibits at the annual convention of the North Western Electrical Association, that created unusual interest, was the vitrified terra cotta conduit of Mr. John T. McRoy, 36 South Clark Street, Chicago. The material used in its construction is shale, which is thoroughly ground and rendered free from all rough particles. During the process of manufacture the terra cotta is subjected to shrinkage to such a degree that a perfectly dense mass is secured, thereby rendering the conduit, when finished, absolutely non-porous. Not only is the terra cotta vitrified throughout, but all surfaces, both interior and exterior, are glazed as an additional precaution against moisture. The interior of the ducts being finished perfectly smooth, with rounded edges, there are no projections to impede the drawing in of the cable. The conduit is manufactured in multiple duct form of any desired number (from one to twelve) and cable capacity. The section lengths are about six feet. As the use of cement or concrete is unnecessary, the services of high priced artisans are not required. The conduits can be installed by comparatively unskilled labor at any season of the year.

SIGNALLING EXTRAORDINARY.

DURING some recent experiments with a view to determining the maximum rate of mechanical transmission by his system of machine telegraphy, Mr. Patrick B. Delany succeeded in producing over an artificial circuit of 250 ohms and 2.95 microfarads, with 115 volts, perfectly legible signals at the rate of 8,000 words per minute. Through 650 ohms the signals were readable, but faint.

This speed required the perforated tape to pass through the transmitter at the rate of 27½ feet per second, and deliver over 2,500 impulses per second at the receiving end of the line. A specimen of the received record may be seen at this office.

SPECIAL LOCAL EDISON EXHIBIT FOR THE MAY EXPOSITION.

One of the most attractive and instructive exhibits at the forthcoming Electrical Exposition will be that of the Edison Electric Illuminating Company, of New York. This display will occupy a space of over one thousand square feet, and will comprise a complete demonstration of the applications of electricity for domestic purposes. The most improved methods of house lighting will be shown in detail, also electric heating, and cooking by electricity. This will be the first time that such a practical exhibition has been made of the many uses to which electricity can be applied in the home, and the understanding of the visitor will be further enlightened by a well arranged display of the various kinds of apparatus employed, all of which will be explained by those in charge of the exhibit. It is safe to predict that, however interesting other exhibits may be, this will be crowded all the time. A large number of other fine displays are already promised and arranged for. All in need of information as to the exhibition should address at once Mr. Clarence E. Stump, the general manager, at 136 Liberty street.

THE NATIONAL UNDERGROUND CABLE COMPANY have opened offices at Nos. 16 and 17 Times building, New York, and are now manufacturing underground cables both for high and low tension. These cables will be covered with the highest grade paper insulation, will be made in all sizes and for all purposes. Our old friends, the National Conduit Manufacturing Company, who are widely known as the largest and most successful contractors for laying underground conduit in this country, own the controlling interest in this company, and have already secured many orders for highly insulated cables from a number of the most important telephone and electric light and power companies. These cables will be manufactured in the factory hitherto occupied by the Norwich Insulated Wire Company, and under their patents. With the excellent reputation of the National Conduit Company, and the well-known high quality of the cable, it is safe to say that success will follow them in their new enterprise.

THE WATERTOWN (N. Y.) STEAM ENGINE COMPANY have recently sold to Russell & Co., of Penn Yan, a 300-horse-power steam plant, comprising a duplex slow speed, double valve automatic engine with two return tubular boilers of 150 horse-power each. The contract was taken under very short notice and installed complete under a contract to forfeit $25 for every day of delay and receive a like premium for every day gained. The plant is for the electric lighting system of the Penn Yan Electric Light Company.

SOUTHERN NOTES.

HANNE BROS., Jacksonville, Fla., in placing their excellent wire reels on the market, have met with much encouragement. They have sent the reels out on thirty days' trial, and before the time due, the invoice was discounted, a sure sign of satisfaction. Employees of telegraph and telephone companies like the reels very much, and are bringing their persuasive powers to bear on the respective purchasing agents.

NEW ENGLAND NOTES.

W. B. W. WELLS, who is well known to electrical people from his connection with fire signal work, has been appointed Superintendent of Streets for the city of Boston. He is a graduate of Harvard, class of '84. He is at present treasurer of the Boston Automatic Fire Alarm Company.

THE WILIAM A. HARRIS STEAM ENGINE COMPANY, of Providence, R. I., has made an assignment to ex-Governor A. O. Bourn and F. A. Harris, with liabilities of $64,000 and assets estimated at $200,000. The trouble is attributed to the scarcity of ready cash.

BRUNSWICK, N. J.—The power house for the Brunswick Traction Company, at Milltown, N. J., will be furnished by the Berlin Iron Bridge Company, of East Berlin, Conn. The engine room will be 64 ft. long, and 85 ft. wide, and the boiler room 45 ft. wide, and 48 ft. long. The side walls are of brick and the roof trusses of iron.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have just completed, for the Newport News Foundry Company, at Hampton, Va., a large foundry, 40 ft. wide and 160 ft. long, the central portion being controlled by a travelling crane. This is one of the best and most modern foundries of the Southern States.

PHILADELPHIA NOTES.

FRANK H. STEWART & CO. have dissolved, by mutual consent, Mr. P. Logan Bockins retiring on account of ill health. The busniess will be conducted by Mr. Frank H. Stewart, under the old name. He will carry a full line of general electrical supplies. They are at present making a specialty of knife switches at cut prices, which they are advertising on another page.

THE STOREY MOTOR AND TOOL COMPANY, of Philadelphia, has issued is very neat and tasteful catalogue of its ingenious motor specialties, several of which have lately been illustrated and described in these pages. Mr. Storey has done notable work in the motor field and is entitled to much credit as well as a large share of the business.

WESTERN NOTES.

THE ABBOTT ELECTRIC AIR COOLING AND PURIFYING COMPANY has been formed at San Francisco, with a capital stock of $1,000,000 by H. W. Abbott, D. G. Depter, A. S. Brackett, M. Strouse, and H. C. Birbee.

MR. J. S. WILSON, Superintendent of the American Circular Loom Company, Boston, Mass., visited their Chicago office last week to confer with their Western agents, Messrs. Brooks and Chandler, on business matters. The prospects of this company's doing a large trade during the year are very encouraging.

LOVELL, MICH.—Sealed proposals for furnishing an electric light and power plant for the city, to consist of 1,000 incandescent lights, 60 arc lights and 100 H. P. for motor service, will be received by Hon. C. Bergin, President of the Board, until 8 o'clock P. M., Feb. 18, 1896. The plant will be run by water wheels located 8 miles from the city. Copies of the specifications can be had by applying to Humphrey & Carr, Engineers, 22 Benedict Building, Detroit, Mich.

THE ELECTRIC APPLIANCE COMPANY have issued and distributed a very attractive calendar for 1896. They have combined with the calendar a carefully prepared moonlight schedule for the entire year of 1896, making the calendar doubly useful as well as ornamental.

THE MANISTEE (MICH.) ELECTRICAL SUPPLY COMPANY has been formed by J. O. Nessew, J. S. Mundy and others, with the object of making electrical apparatus. Fifty men will, it is said, be employed.

THE TRADESMEN'S BANK BUILDING, a large and handsome block being erected in Pittsburg at the present time, will be lighted by electricity from its own plant, which consists of Ball engines, built by the Ball Engine Company, Erie, Pa., direct connected to Westinghouse dynamos.

MR. LUTHER STIERINGER, Consulting Electrical Engineer of the late Atlanta Exposition, was a visitor to Chicago for a few days last week.

MR. MAX A. BERG has resigned his position as manager of the Chicago office of the Ohio Brass Company, and has accepted a responsible position with the same company, at their head office, and works, Mansfield, Ohio.

THE GATES ELECTRIC MANUFACTURING COMPANY, with offices in the Monadnock Building, has made an assignment to the Chicago Title and Trust Company for the benefit of its creditors. The assets are said to be $17,000 and the liabilities about $8,500. The president of the company is J. Holt Gates. The attorney for the assignee said the company had a valuable plant and a number of contracts on hand, but it was unable to make collections. He said the creditors would be paid in full.

MR. W. F. PARISH, general sales manager of the Racine Hardware Co., Marquette Building, Chicago, reports that the number of sales of the engines manufactured by this company during the year 1895 was highly satisfactory. They have sold a large number of their engines for isolated lighting plants throughout the country, and also for the lighting of excursion boats and general ship lighting work. There has also been a considerable demand for small units from 1 H. P. to 15 H. P. for use in mines. They are now making tests of a new design of governor, which will greatly improve the governing operation of their engines, and its work will be such as to insure the closest regulation that has yet been attained, and will render these engines specially adapted for isolated lighting plants. The company have a large and varied stock of vertical and horizontal engines at their works in Racine, Wis., and are now also building center crank horizontal engines of 35 H. P. and upwards.

EMERSON MOTORS.—The trade outlook for 1896, as viewed by the Emerson Electric Manufacturing Company of St. Louis, is extremely encouraging. Not only is their new single-phase alternating current power motor creating great interest, followed by numerous orders from the alternating current fraternity, but their standard line of knife switches and other specialties interest all parties, and their order-book is showing this appreciation in a substantial manner.

WATER POWER UTILIZATION AT OGDEN, UTAH.

The Hon. Frank J. Cannon, of Ogden, Utah, Senator-elect from Utah, makes public the announcement that the final arrangements have been completed in the East whereby the Pioneer Electric Power Company will be able to sell bonds to the amount of $1,500,000 and thus complete the work of utilizing the power in Ogden River canyon. The statement is also confirmed by C. K. Bannister, the engineer of the company.

In 1890 C. E. Mayne organized a local company to develop the power in the river above the city. After an expenditure of $20,000, mostly home capital, Mayne abandoned the scheme and went to San Francisco, but returned in 1893 and resumed the undertaking, but again failed to secure the funds to complete the work. The present company was organized in the fall of 1893 and has been prosecuting the work steadily ever since, but has been hampered by the unwillingness of Eastern capitalists to invest money in enterprises in a Territory. The admission of Utah as a State and the friendliness of the State Constitution to outside investors has aided materially in the success of the Pioneer company in floating its bonds.

The pipe line, power house and electrical machinery for the development of 5,000 horse power must be completed by Sept. 1 of this year and the other 5,000 soon after.

The contract for laying the steel and wooden pipe, which is 30,000 feet in length, has already been let, and the work of laying will begin at once, as there are now two miles of the trench completed. The wooden pipe, six feet in diameter in the clear, will be constructed on the ground and laid as fast as it can be put together, part of the material having already arrived. Bids are to be called for in February for the construction of a large reservoir dam in the valley above the canyon as a preliminary to the development of the remaining 5,000-horse power.

The company is already in possession of contracts with manufacturers by which a number of factories will be located as soon as the company can furnish the power.

AN IMPORTANT EXTENSION OF THE WEST END SYSTEM.

The West End Street Railway Company of Boston has just placed an order with the General Electric Company for four 1,200 K. W. generators and one 1,500 K. W. generator, making a total of 6,300 K. W. in five units. The General Electric Company has also secured an order from the Cataract Construction Company for one 500 K. W. rotary convertor for use in supplying current to the Buffalo and Niagara Falls Railway Company.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. FEBRUARY 19, 1896. No. 407.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—I.

BY

Wm. Baxter, Jr.

THE wonderful rapidity with which the electric motor has invaded the street railway field has created a very general belief that it will not be long before it will enter the domain of the steam locomotive and repeat on a larger scale its extraordinary successes of the past. The general run of men who base their opinions wholly upon what they see and have no technical knowledge by which to be guided, very naturally take it for granted that if electric motors can propel small cars with so much success as to replace horses and cables, that there is no reason why they should not be able to do equally as well with larger cars; and, therefore, that the only thing that can delay the electric invasion of the steam railroad field is the willingness of the managers of these roads to make the change.

The great majority of semi-informed engineers who believe that it is always wise to boom new engineering developments and who are not over-particular about their engineering reputations, were not slow in the early days of electric railways in coming to the front with the most positive assertions to the effect that the locomotive was doomed to oblivion and would only be known as a museum curiosity by the end of the century. These men were not the only enthusiastic advocates of the newcomer. A number of men of wide reputation did not hesitate to assert in the strongest kind of language that the days of steam were numbered. One of the best known electricians, when interviewed on the subject said: "It will displace it if economy, as well as speed and safety, is a factor of locomotion, not because it will make easily a speed of a hundred miles an hour while steam strains itself to make sixty, but because it will get one horse power out of from one to two pounds of cheap coal, while out of six pounds of dear coal a locomotive engine can only get that same one horse power. It will displace it because it will be cheaper."

The language quoted above, as well as several other statements of the same general tenor by men of considerable prominence as engineers, formed the basis of the arguments by which it was sought to prove that electricity would soon be monarch of all it surveyed. Now, as a matter of fact, if electricity is to depend wholly upon the difference in coal consumption between locomotives and large triple expansion stationary engines to obtain a foothold on trunk line railways, it may as well give up the contest at once. Not because the difference in coal consumption is not as great as has been claimed, but because the total cost of fuel forms but a small percentage of the cost of operating a railway system; therefore, even if the entire amount were saved the reduction in running expenses would not be so great as to enable electricity to revolutionize present methods.

It is my object in this article to present the merits upon which electricity can base a claim of superiority, in a fair and impartial manner; therefore, no assumptions will be made that cannot be substantiated directly or indirectly by actual records.

Whenever a controversy arises in any field it is but natural that the most enthusiastic advocates on both sides of the question should lose their judgment and make claims that are, to say the least, somewhat biased in their favor. This has been the case with the majority of writers on both sides of the question of the relative economy of locomotives and stationary engines. There is no such difference in coal consumption between the best type of triple-expansion engines and locomotives as is claimed in the above quotation. The stationary engine has never developed one horse power per pound of coal per hour. An efficiency of two pounds of cheap coal per horse power hour is as much as any conservative engineer would claim. On the other hand, the locomotive is not the great steam annihilator it has been represented to be; on the contrary, it is one of the most economical of non-condensing engines when run at a high speed.

These facts were well known to experts in steam railroading, and they were not slow in showing that the statements made by the advocates of the electric motor were exaggerated. In fact, they were a little too zealous in their efforts to make the best possible showing for the locomotive and went so far as to give the best recorded results as the average performance.

Numerous articles have been published in engineering journals devoted to the interests of locomotives, in which it has been claimed that the coal consumption in some cases is as low as 2½ lbs. and that an average of 3 or 3½ could be safely taken as well within actual every-day results. Such claims, however, are just as far out of the way in favor of steam as the assertions of the advocates of electricity were in the opposite direction.

THE WESTINGHOUSE—BALDWIN ELECTRIC LOCOMOTIVE.

The first of the electric locomotives built jointly by the Westinghouse Company, and the Baldwin Locomotive Works has arrived in Pittsburg and will be used for heavy hauling in the yards at East Pittsburg.

It is the size of a common box car, being 30 feet long. It is built entirely of steel, and is mounted upon eight wheels, 42 inches in diameter. It will be geared for 800 horse power, but can for a short period exert 1,600 horse power. At the former power the new locomotive can draw a loaded freight train 40 miles an hour, and at the latter power 80 miles. It is operated by one man, in a way similar to the common trolley. The cost is said to equal that of a steam locomotive, and the weight of this first one is 60 tons.

air brakes the seven eight-wheel combination postal and passenger cars of the Brooklyn Heights Railroad Company. These cars weigh over ten tons each, exclusive of passengers and mails, and travel over routes having very heavy grades, so that a brake more powerful than the ordinary hand brake was absolutely necessary for safety and speed. The speed of these postal cars may occasionally rise to such a point as to make the quick and certain application of brakes important, and the fact that the "Standard" air brakes have been chosen for this service is significant. It is worthy of note, by the way, that with the Standard air brake there is said to be little difficulty in using the sand boxes. In cases of emergency, the motorman throws his handle completely over and sets the brake and can then devote his entire attention to properly sanding the track. The company now offers a special device by which with one turn of the handle sand is run out and the air brake applied.

The car shown in Fig. 4 is in service on the Pasadena and

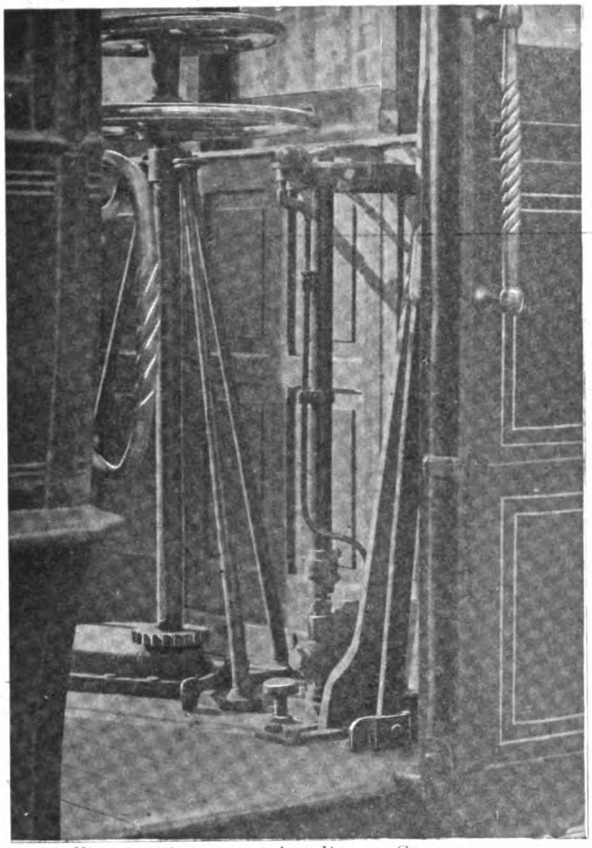


FIG. 4.—STANDARD AIR BRAKE CONTROLLER.

Los Angeles Railway Company's route. There are two forty-horse power motors of latest design used, making eighty-horse power per car. Every car is equipped with the "Standard" air brake, a necessity, since the grades range from 3 to 7.6 per cent. In this connection it is interesting to know that the Standard Air Brake Company has just received the third order from the management of that road. This fact speaks for itself, especially as the original brakes are in their second year of operation.

We may also mention another recent application of the "Standard" brakes, and that is on the cars of the Washington, Alexandria & Mt. Vernon Railway Co. This road will operate its cars at very high speeds, up to forty-five miles per hour, on account of which, and of the motor and truck arrangement, the Standard Company is using its geared compressor type. These compressors are not mounted on the motor axles, but on the small wheel axles of the Brill maximum traction trucks. A high efficiency is said to have been developed by these compressors in recent trials. These are but a few of the latest application of "Standard" air brake, the use of which is rapidly extending, not only in the United States, but also abroad, whither a large number of equipments have been recently shipped.

AN ELECTRIC RAILWAY BRIDGE FOR NIAGARA.

Senator Ellsworth has at Albany introduced a bill to incorporate the Lewiston Connecting Bridge Company, to construct a bridge on the east bank of the Niagara River in the town of Lewiston, Niagara County, south of the village of Lewiston, to some point in Canada, on the west bank of the Niagara River. By the bill the company is authorized to lay tracks and operate a railroad by electrical or any power other than locomotive steam power and to lay pipes to convey gas and water and cables to transmit electricity or other motive power. The capital stock is to be $200,000, divided into $100 shares. The stock may be increased to $500,000. Charles H. Smyth, of Clinton; John T. Mott, of Oswego; Joseph S. Bryant and John M. Bostwick, of Buffalo, and T. Hotchkiss, of Lewiston, are named as commissioners to locate the bridge.

TROLLEY ON GETTYSBURG BATTLEFIELD.

In the United States Supreme Court Justice Peckham has handed down an opinion sustaining the right of the government to condemn portions of the Gettysburg battlefield for public use, which has been acquired by the Gettysburg Electric Company to lay their tracks upon.

The opinion of the court dealt with the case involving the right of the government to condemn the real estate of the Gettysburg Electric Railway Company as a part of the National Park ,located upon the Gettysburg battleground. The court below (Judge Dallas, of Philadelphia) had decided that the act of Congress authorizing the establishment of the park in so far as it applied to the condemnation of private property was unconstitutional and that there was no right under it to condemn. The proceedings to condemn were begun under authority of an act of Congress appropriating money to pay for the ground.

TWO CENT PER MILE RATE IN OHIO.

The numerous electric railrods in northern Ohio are causing the steam roads a great deal of anxiety by taking from them short haul freight and passengers. The Erie company has taken the bull by the horns and decided to reduce the passenger rates in the region of Youngstown and Warren to the level of the fares charged by the competing electric lines there. The Cleveland, Canton and Southern Railroau has already made a reduction of 2 cents per mile on certain round trip tickets.

CONNECTICUT TROLLEY PARALLELS.

The Norwalk City Council voted on Jan. 18 to give the Norwalk Tramway Company permission to extend its trolley line to Westport, a distance of about three miles. When that line is completed there will be only a gap of about four miles between the Norwalk Tramway Company's system and the system of the Bridgeport Traction Company, now reaching to Southport, and with that gap eliminated the New Haven Steam Company's main system will be paralleled by trolley roads for a distance of about twelve miles between Bridgeport and Norwalk and South Norwalk. This is an important part of the New Haven company's line for local travel. Figures presented by the latter corporation to the State Legislature at the last session showed, for example, that between Bridgeport and Southport during six months the local passenger travel had decreased by 5,131 passengers, or about 25 per cent., as compared with the year 1894, when no electric competition existed. Between Bridgeport and Fairfield—somewhat nearer Bridgeport than Southport—the traffic during three test months of the same period fell off on the New Haven road 60 per cent., owing to the opening of the trolley line. The only chance probably of blocking the new lines is an appeal by the steam company to the Superior Court, which, under the general street railway law of the State, can rule that a parallel line is not demanded by public necessity or convenience.

An examination of the whole trolley system of Connecticut shows that the steam railroads of the State are now paralleled by trolleys for a distance of about 101 miles, and that about one-third of all the trolley roads parallel steam roads more or less directly. The New Haven steam road is paralleled about sixty miles, the New England road (controlled by the New Haven corporation) about twenty-eight miles, and the Philadelphia & Reading and New England about 13 miles. Trolley roads almost certain soon to be built or actually in construction now will add about thirty-four miles, of which sixteen miles will parallel the New Haven road, six miles the New England, and twelve miles the New London Northern. On the basis of last year's official figures of the results of competition on passenger traffic, the indications are, however, that the total loss of the steam companies by electric rivalry does not now exceed $100,000 a year as compared with the period before any trolleys had been built. In such a comparison it must be remembered that a large portion of the trolley parallels represent merely the substitution of electricity for horse power on all street railroads paralleling steam lines.

ELECTRIC LIGHTING.

THE NATURE OF THE X-RAYS.

BY WILLARD E. CASE.

IN the last number of "The Electrical Engineer" the writer described an experiment in which the rays emanating from a cathode terminal excited by an induction coil cast a shadow of the anode terminal upon a sensitive plate placed beyond the latter. The arrangement adopted is illustrated in the accompanying diagram, Fig. 1. A print of the shadow obtained on the sensitive plate is shown in Fig 2.

Another interesting fact observed, as already stated,

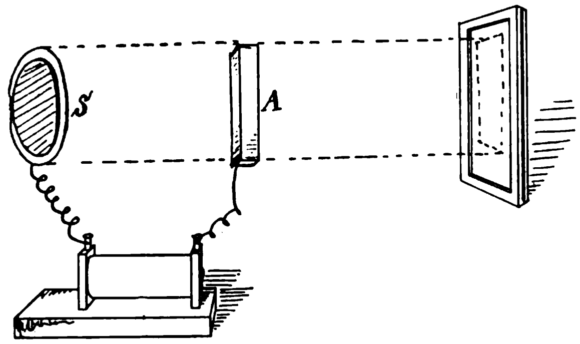

FIG. 1.

was that when a vacuum tube was placed in the vicinity of a condenser plate and sensitized photographic plate, the rays seemed to be deflected and an imperfect shadow of the object photographed was obtained. From these experiments it would appear that sensitized plates can be acted upon in any place in which vacuum tubes would glow. It is well known that a vacuum tube will glow when attached to the terminal of an induction coil with one wire only, or when placed between two condenser plates, even if solid objects surround it, such as wood, glass, etc. We know that vacuum tubes will glow at a long distance from the point of origin of the oscillations, so that photography

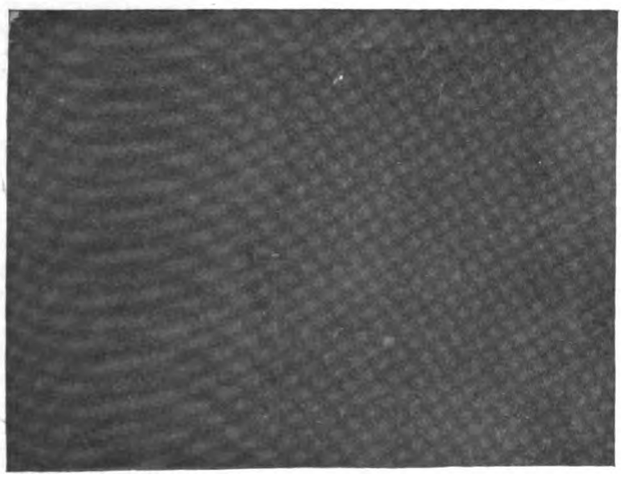

FIG. 2.

by this method is not limited to small distances, nor to any light which can be observed by the eye. The fact that the vacuum tube before mentioned deflected the rays and caused an imperfect shadow might tend to show that the vacuum was the path of less resistance for this electrical action.

This naturally raises the question whether or not the action is the electric oscillations described by Hertz or due to the cathode rays mentioned by Lenard, or due to the radiant matter so thoroughly investigated by Crookes. If it is due to what might be called the Crookes effect, or radiant matter, it naturally suggests itself to one's mind that many of his devices might be utilized for controlling this force, if the rays could be focused more thoroughly, and more immediate effects might be obtained.

Take, for example, Crookes' focused mirror tube. The bulb would be constructed of aluminum instead of glass, and the electrodes arranged after the Crookes method. The curvature of the mirror should be such that the focus would be outside of the tube, and the object to be photographed could be placed in the desired position. If the action is due to the Hertz effect, the rays might be focused by means of a lens made of pitch, such as he suggested and constructed.

The Röntgen method of photography which so astonished the world and opened up such tremendous fields for investigation has come upon us so suddenly that one can only make experiments, record them and give them to the world for what they may later prove to be worth. Within a month it has been discovered that hidden objects could be photographed with a new light, and within the same period other investigators have found that no light was needed.

Crookes, in 1879, in his lecture delivered before the British Association for the Advancement of Science at Sheffield, [1]stated that radiant matter in a vacuum tube when intercepted by solid matter, casts a shadow and that the radiant matter goes from one pole to the other in straight lines. From the experiments that I have made, heretofore described, it would appear that we have something analogous to the Crookes effect going on in the atmosphere, and if so, as we think is proved by the arrangements and photograph here shown and described, electrical energy can be transmitted from its source, the condenser plate, to the object to be photographed without light and its shadow thrown to a distance, where it may be photographed.

PHOTOGRAPHING HIDDEN OBJECTS BY THE ARC LIGHT.

BY

J. Hart Robertson

WHILE the scientific world to-day is agitated over Röntgen's discovery, it will, no doubt, interest many to learn that the more or less complicated apparatus, such as experimenters are now using, is not necessary to produce the results obtained by Röntgen.

The result of an experiment referred to further on shows that what have been called the X or cathode rays (at least as produced by high potential alternate currents) are not essential. It also demonstrates the fact that it is not necessary to use the vacuum bulb in producing Röntgen's effects, and also that what are known as magnetic lines of force are very closely allied to this subtle something that has the inherent power to penetrate substances that hitherto were supposed to be proof against every known force, except magnetism.

The semi-magnetic lines of force penetrate through different substances from which light is absolutely excluded, and have to a great extent the penetrating power of magnetic lines of force, only differing from these in so far as their power to pass through some media; or, in

[1]This lecture appears on page 189.

other words, whilst magnetic lines of force will seemingly pass through one substance as quickly as through another, these semi-magnetic lines of force will pass quicker through some media than through others.

This may be due, and probably is, to some, at present, unknown force, combined with magnetic lines of force, which produce a retarding effect on the same and cause them to take a more roundabout path through some substances than they otherwise would.

Experiments are now being conducted which may show that magnetic lines of force alone, when properly directed, will produce all, and more, of the effects which have been credited to the "X" or cathode ray.

In talking with an experimenter in photography, Mr. Guion Thompson, of Harrisburg, Pa., I suggested that an arc lamp would produce all the effects that the cathode rays have been credited with. To demonstrate this fact, one evening during the week ending Feb. 8, a temporary arc lamp, consisting of two carbon rods lightly clamped on a board, so that one could easily be manipulated by hand, were put in circuit with 25 storage cells and placed in a horizontal position, so that the box containing the sensitive plate could be placed over the arc.

The box, which was made of hard wood, one-fourth of an inch thick, with sliding cover on top, fitting into groves in same, contained, besides the sesitive plate, a piece of irregularly shaped ferrotype metal and a piece of ordinary glass, each of which overlapped the sensitive plate about one-quarter of its surface. These were placed in the bottom of the box. The box was filled with maroon-colored fabric and the cover slid tightly on. Pieces of brick were used at about two inches above the arc. Through a fuse burning out, the exposure only lasted one minute, but when the plate was developed it was seen that even with that short exposure the semi-magnetic lines of force had penetrated the box and left their impression on the plate.

One side of the plate showed the ferrotype metal exactly as it was, although the impression was faint. The part overlapped by the piece of glass showed that no effect whatever had taken place, and that the glass acted the same as when used with cathode rays, in so far as it interfered with the rays penetrating through it and reaching that part of the plate immediately over it.

As far as I am aware, this is the first time that an arc light has been used to produce this wonderful effect. There, no doubt, would have been some publication of the fact if it had been accomplished before.

The use of an arc allows of great possibilities being accomplished, as there is no necessity for any intricate apparatus, and the arc can be kept in one position, so that either a short or long exposure can be made without any trouble.

Possibly any substance can be penetrated by these lines of force, and all that will be necessary will be to have a longer exposure with some materials than with others.

GROWTH OF THE MANCHESTER, N. H., ELECTRIC LIGHT CO.

The business of the above corporation for the past year has been satisfactory. There has been quite a considerable increase in the gross earnings and a very good showing of net earnings. The calls upon the company for extensions and construction have been very large, especially in the street lighting and power departments. The addition to the property during the past twelve months consists of two 150-horse-power boilers, one condensing engine, 500 horse power; one 1,000-horse-power condenser, extensive additions to the steam piping, 125-light arc machine, one 300-kilowatt generator, and one 200-kilowatt generator, and one standard railway switchboard. Additions have been made to the real estate to the extent of one brick building, 41x38, and wooden structure, 33x44. The officers for 1896 are: A. Elliott, president; H. E. Parker, vice president; W. G. Africa, treasurer; J. Brodie Smith, superintendent; J. W. Hildreth, clerk.

CATHODOGRAPHS BY THE DISCHARGE OF LEYDEN JARS AND OTHER DISRUPTIVE DISCHARGES OF STATIC ELECTRICITY.—A NEW METHOD OF PRODUCING ROENTGEN RAYS.

BY

William James Morton, M.D.

The writer, in a recent communication to this journal (Feb. 5) published an article stating that the Röntgen rays—up to that time supposed to require an induction coil and a Crookes tube for their production—were also produced in the open air and in the space intervening between the discharging rods of a static machine. This fact he has since amply confirmed. It is here not so much a question of a brush discharge, as it is

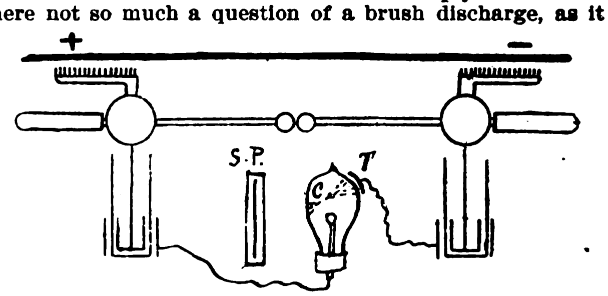

FIG. 1.

of phenomena associated with the disruptive discharge, the projectile cathodic rays, so to speak, existing in space about the disruptive discharge as well as in it. The cathodograph I then showed, although crude, was a true shadow picture, in contradistinction to a familiar effect which may be easily produced upon sensitive plates when metallic objects are placed near to them, or upon them, and are electrified or themselves directly convey electricity in the shape of a fine brush discharge through such sensitive plates. This distinction I made clear in the article referred to.

Having thus primarily recorded the important fact that the

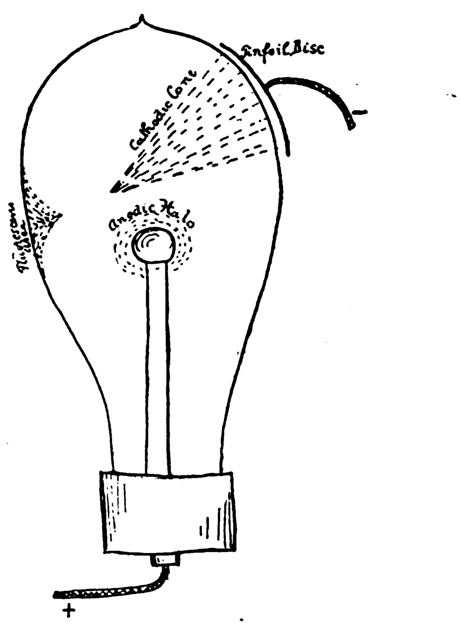

FIG. 2.

Röntgen rays are an associate incident of the disruptive discharge of static machines, and, of course, by analogy, of all other discharges of a similar nature, the pathway to further experimentation was clearly indicated.

Omitting the details of many preliminary experiments, I will come directly to a final and conclusive one, which demonstrates the unquestionable fact that cathodography on a large

and intense scale can be pursued and accomplished simply by the aid of charged Leyden jars alone. The often-quoted and well-authenticated shadowgraphs or pictures produced by the lightning discharge—that mighty disruptive and oscillatory electric current of nature—upon the human body, of objects intervening between it and the discharge, and due, probably, to the interception of these same Röntgen rays by the intervening object, might, indeed, have suggested to us that the disruptive discharge from static machines, and particularly from Leyden jars, would make the repetition of the experiment on a small scale feasible. For just as now in a vacuum tube, when the discharge between the anode and the cathode takes place, the cathodic rays are thrown off with projectile force against the walls of the bulb, so in the statical disruptive discharge, similar projectile radiations may be presumed to exist.

The experiment alluded to above, with Leyden jar oscillatory currents in connection with vacuum tubes, I have now made, fully and from many points of view and with unvarying success. I describe in detail one method of utilizing disruptive discharge currents, which produces the Röntgen rays in a most intense, practical and manageable manner. This method consists in utilizing a current discharge from static machines provided with Leyden jars, or even not so provided, which I described in 1881, and again in an extended paper, with many illustrations, in 1891. This current I termed, in the infancy of thought on this subject, the "static induced current." Its essential feature was the introduction of a spark gap into an otherwise inoperative circuit of the static machine and the excitation of a regulated and periodic flow along a conductor, of an oscillatory discharge of high frequency between the external armatures of Leyden jars. The method of its production may be exemplified by reproducing the connections from the illustrations then published (see Fig. 1). The only change in this cut is to substitute a vacuum bulb in the circuit in place of the ordinary electrodes then shown. Sensitive plates exposed to this vacuum bulb, even at great distances, exhibit all the familiar Röntgen effects, as also do fluorescent substances.

A word may be said as to the nature of the vacuum bulb. Any vacuum bulb may be excited when properly attached to the circuit above described. I happened to have on hand such a vacuum bulb of peculiar construction, described and illustrated, with exactly the same connections as above given in the transactions of the American Institute of Electrical Engineers, of November, 1893, page 604 (see Fig. 2). It is constructed with only one entering terminal, which in this instance is a small ball. This terminal I constitute an anode. Upon the outside of the vacuum tube I fasten a disc of metal, commonly tinfoil, which constitutes a cathode.

The Röntgen rays thus produced are of extraordinary power and intensity. They blacken sensitive films deeply, they penetrate metallic objects, with even too great intensity for near exposure, and the trouble I have found in securing satisfactory pictures is in reducing the time of exposure and lengthening the distance, rather than to the contrary. It is difficult to conceive of the extent to which this new method may be carried when the batteries of Leyden jars filled by powerful Ruhmkorff coils, are brought into play, and it is my belief that in this new method will be found much of the future extension of practical work with the Röntgen rays.

PROF. SCHUSTER ON ROENTGEN'S RAYS.[1]

Professor Röntgen's remarkable discovery will materially affect our views concerning the relation between the ether and matter; but further experimental evidence is required before any opinion can be expressed as to the character of the rays, which behave in so straightforward a manner that they seem to upset all one's notions of the laws of nature. Professor Röntgen, on the strength of his carefully-conducted experiments, has arrived at a conclusion adverse to the idea that the rays only differ from light rays by the smallness of wave-length. Perhaps the following considerations may show that the evidence is not conclusive in this respect:

Röntgen's rays are not cathode rays—there can be no doubt on that point—but they are generated at the point of impact between the cathode ray and solid substances.

The discoverer has not been able to obtain any interference effects, possibly, as he says, owing to the weakness of the radiation. An absence of interference would not, however, be sufficient to show that the radiation is not of the nature of ordinary light, but only that it does not possess sufficient regularity, or, in other words, that the disturbance is not sufficiently homogeneous. That this is the case is not at all improbable, for the radiation is produced by an impact, which in the first instance may be an impulsive motion propagated outwards, and after passing through the screen, would only possess such regularity as is impressed on it by the absorption of the longer waves.

The great argument against the supposition of waves of very small length lies in the absence of refraction; but is this conclusive?

When we speak of the size of the atoms, we mean their distance in the solid and liquid state. The properties of the ether may remain unaltered within the greater part of the sphere of action of a molecule. The number of molecules lying within a wave-length of ordinary light is not greater than the number of motes which lie within a sound-wave, but, as far as I know, the velocity of sound is not materially affected by the presence of dust in the air. Hence there seems nothing impossible in the supposition that light-waves, smaller than those we know of, may traverse solids with the same velocity as a vacuum. We know that absorption bands greatly affect the refractive index in neighboring regions; and as probably the the whole question of refraction resolves itself into one of resonance effects, the rate of propagation of waves of very small lengths does not seem to me to be pre-judged by our present knowledge. If Röntgen's rays contain waves of very small length, the vibrations in the molecule which respond to them would seem to be of a different order of magnitude from those so far known. Possibly we have here the vibration of the electron within the molecule, instead of that of the molecule carrying with it that of the electron.

I should like, further, to express a certain sense of satisfaction that Röntgen's rays are not deflected in a magnetic field. They are thus clearly separated from cathode rays. The idea that cathode rays are due to vibrations has become fashionable; yet the fact that the magnet deflects them just as it would an electrified molecule, has always semed to me to be conclusive against this view. No one has, so far, given any plausible reason why a ray of invisible light should be able to run round in a spiral, while a ray of visible light goes straight; and, so far, Röntgen's rays behave as we should expect well-conducted vibrations to do.

It is not my intention to argue in favor of any particular theory, or against Röntgen's suggestion that we have at last found the formerly missed longitudinal wave. I only desire to put those points forward which at first sight seem to go against the supposition of ordinary light vibrations, and to raise the question whether they constitute an insuperable difficulty.

[1]From "Nature."

ARE ROENTGEN'S RAYS DUE TO CONDENSATIONAL WAVES?—LORD KELVIN'S EARLY VIEWS.[1]

BY J. T. BOTTOMLEY.

In connection with the wonderful discovery by Professor Röntgen of photographic rays, apparently hitherto unknown, and in connection with the speculation which concludes Professor Röntgen's most interesting paper, that these rays may perhaps be longitudinal vibrations of the luminiferous ether, the following extracts will probably be found of interest. They are taken, by permission of Lord Kelvin, from his Baltimore lectures, delivered at the Johns Hopkins University in 1884.

The first extract is from the reprint (now in progress) of Lecture IV. Referring to mathematical work immediately preceding, Lord Kelvin says:

"Suppose that we have at any place in air, or in luminiferous ether (I cannot distinguish now between the two ideas) a body that, through some action we need not describe, but which is conceivable, is alternatively positively and negatively electrified; may it not be that this will give rise to condensational waves? Suppose, for example, that we have two spherical conductors united by a fine wire, and that an alternating electromotive force is produced in that fine wire, for instance, by an alternate current dynamo-electric machine; and suppose that sort of thing goes on away from all other disturbance—at a great distance up in the air, for example. The result of the action of the dynamo-electric machine will be that one conductor will be alternately positively and negatively electrified, and the other conductor negatively and positively electrified. It is perfectly certain, if we turn the machine slowly, that in the air in the neighborhood of the conductors we shall have alternately positively and negatively directed electric force with reversals of, for example, two or three hundred per second of time, with a gradual transition from negative through zero to positive, and so on; and the same thing all through space; and we can tell exactly what the potential and what the electric force is at each instant at any point. Now, does any one believe that, if that revolution were made fast enough, the electro-static law of force, pure and simple, would apply to the air at different distances from each globe? Every one

[1]From "Nature."

believes that if that process be conducted fast enough, several million times, or millions of millions times per second, we should have large deviations from the electro-static law in the distribution of electric force through the air in the neighborhood. It seems absolutely certain that such an action as that going on would give rise to electrical waves. Now, it does seem to me probable that those electrical waves are condensational waves in luminiferous ether; and probably it would be that the propagation of these waves would be enormously faster than the propagation of ordinary light waves.

"I am quite conscious, when speaking of this, of what has been done in the so-called electro-magnetic theory of light. I know the propagation of electric impulse along an insulated wire, surrounded by gutta-percha, which I worked out myself about the year 1854, and in which I found a velocity comparable with the velocity of light. We did not then know the relation between electro-static and electro-magnetic units. If we work that out for the case of air instead of gutta-percha we get simply v (that is, the number of electro-static units in the electro-magnetic unit of quantity) for the velocity of propagation of the impulse. That is a very different case from this very rapidly varying electrification I have ideally put before you, and I have waited in vain to see how we can get any justification of the way of putting the idea of electric and magnetic waves in the so-called electro-magnetic theory of light.

"I may refer to a little article of mine in which I gave a sort of mechanical representation of electric, magnetic, and galvanic forces—galvanic force I called it then, a very badly-chosen name. It is published in the first volume of the reprint of my papers. It is shown in that paper that the static displacement of an elastic solid follows exactly the laws of the electrostatic force, and that rotatory displacement of the medium follows exactly the laws of magnetic force. It seems to me that an incorporation of the theory of the propagation of electric and magnetic disturbances with the wave theory of light is most probably to be arrived at by trying to see clearly the view that I am now indicating. In the wave theory of light, however, we shall simply suppose the resistance to compression of the luminiferous ether, and the velocity of propagation of the condensational wave in it, to be infinite. We shall sometimes use the words 'practically infinite' to guard against supposing these quantities to be absolutely infinite."

The second extract which I give is from p. 143 of the Papyrograph edition of the "Baltimore Lectures"—a portion not yet reprinted.

"The want of indication of any such actions is sufficient to prove that if there are any in nature, they must be exceedingly small. But that there are such waves, I believe, and I believe that the velocity of propagation of electro-static force is the unknown condensational velocity that we are speaking of.

"I say 'believe' here in a somewhat modified manner. I do not mean that I believe this as a matter of religious faith, but rather as a matter of strong scientific probability."

PHOTOGRAPHING AND SEEING IN DARKNESS.

BY

G. d'Infreville

ON Jan. 22 I claimed in "The Electrical Engineer" priority of invention on a process for photographing and seeing in darkness, but, following the advice of friends, I did not disclose the manner of carrying it out in practice.

Some recent articles published in the newspapers and referring more or less to this subject, render it advisable that I should publish what I have been working at for years, as I can easily prove by numerous witnesses, explaining at the same time in a way intelligible to those versed in the art how it can be done.

The process consists of two parts. The first is to cast upon the object to be photographed or seen rays invisible to the human eye, namely, ultra-violet rays. Here I may state that the ultra-violet rays extend about seven times as far beyond the violet as the visible spectrum itself, and I may also say that I incline to believe that the Röntgen rays are far up in the ultra-violet, and for the following reasons:

Swinton has shown that they behave like ultra-violet rays as regards solutions of bisulphide of carbon and of alum. Of greater weight yet is the fact that they fluoresce. Fluorescence is due to rays placed in the spectrum above the color of the fluorescence.

The contrary phenomenon, that of colorescence, has not been so clearly demonstrated.

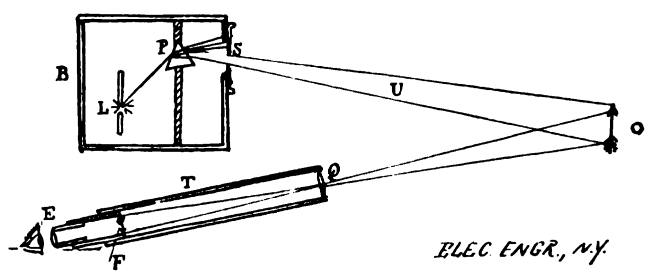
Ultra-violet rays exist in the sunlight and reach the earth's surface when not prevented by the vapor or the dust in the atmosphere. They can also be obtained from the electric arc, whether in free or rarefied air or gases. Magnesium light is very rich in ultra-violet rays, and of late it appears that acetylene gas is remarkable in this respect. The flame of sulphur, especially in oxygen, that of oxide of carbon, and of alcohol, also furnish more or less said rays.

To render the above lights or the objects they illuminate invisible to the naked eye can be obtained by well-known methods. Said rays can be filtered through a solution of iodine between two plates, said plates being such that they allow the ultra-violet rays to pass. As there is, however, no kind of glass known to allow ultra-violet rays to pass freely, I prefer to decompose the light from the source through a quartz prism, to cut off by a proper adjustable shutter all the visible rays and to allow only the ultra-violet rays to pass out and to fall upon the objects which it is desired to photograph or to see, either by reflection or transparency. Gratings are also a well-known means for decomposing the light and obtaining ultra-violet rays.

The second part of my process is to render apparent the objects illuminated as above explained. The objects being thus subject to the invisible light of the ultra-violet rays, I will explain how they can be photographed or seen.

First, how photographed. Referring to the accompanying sketch, I make use of an objective made of quartz or other substance or combination of substances, which allow the passage of the ultra-violet rays while refracting them. The camera itself ought to be plated with glass or lead plates or other material, and of sufficient thickness, so as to protect the sensitive plate from the action of the ultra-violet rays.

A glass frame, coated with some proper fluorescent substance, such as solution of bisulphate of quinine or platino-



D'INFREVILLE'S METHOD OF SEEING IN DARKNESS.

cyanide of barium will take the place of the ordinary ground glass plate used to bring it to correct focus.

The plate chosen ought to be most sensitive to ultra-violet rays, and have been particularly previously shielded by proper wrapping against the action of the ultra-violet rays from any source. It is then put in position and an exposure is made, the time of which can vary from instantaneity to a greater or less period. It can be developed afterwards in a dark room, which must be, like the camera, shielded against the action of any rays from the outside which can affect said plate.

Secondly, as to seeing. I employ for the objective of the telescope or the objectives of the binocular telescopes, a lens, Q, made of quartz or other materials capable of refracting the ultra-violet rays without absorbing them. I receive the image formed inside of the telescope on a plate, F, made of some proper fluorescent substance or, preferably, of thin glass, or other transparent material coated with some fluorescent substance or combination of substances, in order to obtain certain desirable combinations of colors or a greater range of action. A solution of bisulphate of quinine in gum arabic or platinocyanide of barium will also be found suitable here.

The rays which have not been absorbed by the object to be seen pass through the telescope quartz objective, Q, fall upon the plate of fluorescent material, F, where they appear and can be seen from the other side by the ordinary convex ocular glass used in telescopes in case the fluorescent plate is transparent. It can also be observed from the other side by reflection, which is necessary if the fluorescent plate is not transparent.

A quartz prism giving total reflection can also be used in combination with the ocular, the reflecting face of the prism being coated with the fluorescent material. Some luminous paints can also be used if the image is to remain steady. The object can in some cases be seen by transparency instead of by reflection, and some curious effects are obtained. In this case the quartz objective of the telescope can be dispensed with and the fluorescent plate can be enlarged.

I said in my article of Jan. 22 that the process carried with

itself its own remedy. I will now explain. Any object covered with some fluorescent substance, as, for instance, painted with a solution of bisulphate of quinine or uranium glass would indicate immediately by its fluorescence that a light invisible to the eye is being projected upon it.

I wish to conclude by stating that my process has been attested by Mr. T. Commerford Martin, editor of "The Electrical Engineer," and had been communicated to several other persons before a process similar in some respects to mine was published and that I have been experimenting on it to the knowledge of several persons for many years past.

ON RADIANT MATTER.[1]—I.

BY WILLIAM CROOKES, F. R. S.

TO throw light on the title of this lecture I must go back more that 60 years—to 1816. Faraday, then a mere student and ardent experimentalist, was twenty-four years old, and at this early period of his career he delivered a series of lectures on the general properties of matter, and one of them bore the remarkable title, "On Radiant Matter." The great philosopher's notes of this lecture are to be found in Dr. Bence Jones's "Life and Letters of Faraday," and I will here quote a passage in which he first employs the expression radiant matter:

> If we conceive a change as far beyond vaporization as that is above fluidity, and then take into account also the proportional increased extent of alteration as the changes rise, we shall perhaps, if we can form any conception at all, not fall far short of radiant matter; and as in the last conversion many qualities were lost, so here also many more would disappear.

Faraday was evidently engrossed with this far-reaching speculation, for three years later—in 1819—we find him bringing fresh evidence and argument to strengthen his startling hypothesis. His notes are now more extended, and they show that in the intervening three years he had thought much and deeply on this higher form of matter. He first points out that matter may be classed into four states—solid, liquid, gaseous, and radiant—these modifications depending upon differences in their several essential properties. He admits that the existence of radiant matter is as yet unproved, and then proceeds in a series of ingenious analogical arguments, to show the probability of its existence.[2]

If, in the beginning of this century, we had asked, What is a gas? the answer then would have been that it is matter, expanded and rarefied to such an extent as to be impalpable, save when set in violent motion; invisible, incapable of assuming or of being reduced into any definite form like solids, or of forming drops like liquids; always ready to expand where no resistance is offered, and to contract on being subjected to pressure. Sixty years ago such were the chief attributes assigned to gases. Modern research, however, has greatly enlarged and modified our views on the constitution of these elastic fluids. Gases are now considered to be composed of an almost infinite number of small particles or molecules, which are constantly moving in every direction with velocities of all conceivable magnitudes. As these molecules are exceedingly numerous, it follows that no molecule can move far in any direction without coming in contact with some other molecule. But if we exhaust the air or gas contained in a closed vessel, the number of molecules becomes diminished, and the distance through which any one of them can move without coming in contact with another is increased, the length of the mean free path being inversely proportional to the number of molecules present. The further this process is carried the longer becomes the average distance a molecule can travel before entering into collision; or, in other words, the longer its mean free path, the more the physical properties of the gas or air are modified. Thus, at a certain point, the phenomena of the radiometer become possible, and on pushing the rarefaction still further—i. e., decreasing the number of molecules in a given space and lengthening their mean free path—the experimental results are obtainable to which I am now about to call your attention. So distinct are these phenomena from anything which occurs in air or gas at the ordinary tension, that we are led to assume that we are here brought face to face with matter in a fourth state or condition, a condition as far removed from the state of gas as a gas is from a liquid.

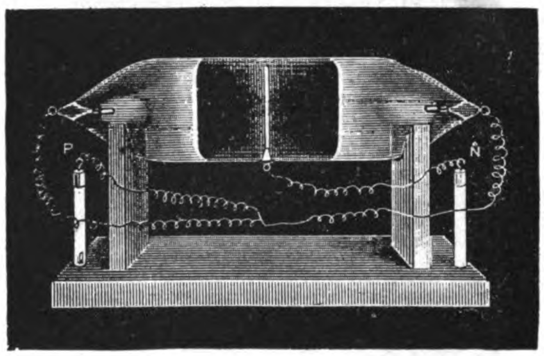


FIG. 1.

MEAN FREE PATH—RADIANT MATTER.—I have long believed that a well-known appearance observed in vacuum-tubes is closely related to the phenomena of the mean free path of the molecules. When the negative pole is examined while the discharge from an induction coil is passing through an exhausted tube, a dark space is seen to surround it. This dark space is found to increase and diminish as the vacuum is varied, in the same way that the mean free path of the molecules lengthens and contracts. As the one is perceived by the mind's eye to get greater, so the other is seen by the bodily eye to increase in size; and, if the vacuum is insufficient to permit much play of the molecules before they enter into collision, the passage of electricity shows that the "dark space" has shrunk to small dimensions. We naturally infer that the dark space is the mean free path of the molecules of the residual gas, an inference confirmed by experiment.

I will endeavor to render this "dark space" visible to all present. Here is a tube (Fig. 1), having a pole in the center in the form of a metal disk, and other poles at each end. The center pole is made negative, and the two end poles connected together are made the positive terminal. The dark space will be in the center. When the exhaustion is not very great, the dark space extends only a little on each side of the negative pole in the center. When the exhaustion is good, as in the tube before you, and I turn on the coil, the dark space is seen to extend for about an inch on each side of the pole.

Here, then, we see the induction-spark actually illuminating the lines of molecular pressure caused by the excitement of the negative pole. The thickness of this dark space is the measure of the mean free path between successive collisions of the molecules of the residual gas. The extra velocity with which the negatively electrified molecules rebound from the excited pole keeps back the more slowly moving molecules which are advancing toward that pole. A conflict occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the discharge.

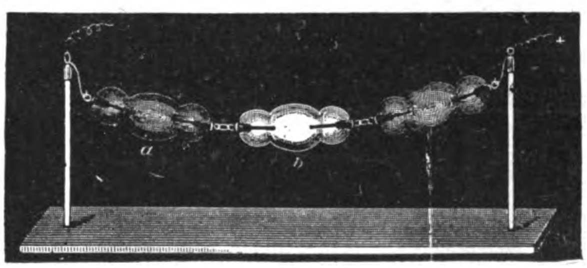

FIG. 2.

---

1. A lecture delivered before the British Association for the Advancement of Science, at Sheffield, Friday, August 22, 1879.

2. I may now notice a curious progression in physical properties accompanying changes of form, and which is perhaps sufficient to induce, in the inventive and sanguine philosopher, a considerable degree of belief in the association of the radiant form with the others in the set of changes I have mentioned.

As we ascend from the solid to the fluid and gaseous states, physical properties diminish in number and variety, each state losing some of those which belonged to the preceding state. When solids are converted into fluids, all the varieties of hardness and softness are necessarily lost. Crystalline and other shapes are destroyed. Opacity and color frequently give way to a colorless transparency, and a general mobility of particles is conferred.

Passing onward to the gaseous state, still more of the evident characters of bodies are annihilated. The immense differences in their weight almost disappear; the remains of difference in color that were left are lost. Transparency becomes universal, and they are all elastic. They now form but one set of substances, and the varieties of density, hardness, opacity, color, elasticity, and form, which render the number of solids and fluids almost infinite, are now supplied by a few slight variations in weight, and some unimportant shades of color.

To those, therefore, who admit the radiant form of matter, no difficulty exists in the simplicity of the properties it possesses, but rather an argument in their favor. These persons show you a gradual resignation of properties in the matter we can appreciate as the matter ascends in the scale of forms, and they would be surprised if that effect were to cease at the gaseous state. They point out the greater exertions which Nature makes at each step of the change, and think that, consistently, it ought to be the greatest in the passage from the gaseous to the radiant form.—"Life and Letters of Faraday," vol. 1., p 308.)

Therefore the residual gas—or, as I prefer to call it, the gaseous residue—within the dark space is in an entirely different state to that of the residual gas in vessels at a lower degree of exhaustion. To quote the words of our last year's President, in his address at Dublin:

"In the exhausted column we have a vehicle for electricity not constant like an ordinary conductor, but itself modified by the passage of the discharge, and perhaps subject to laws differing materially from those which it obeys at atmospheric pressure."

In the vessels with the lower degree of exhaustion, the length of the mean free path of the molecules is exceedingly

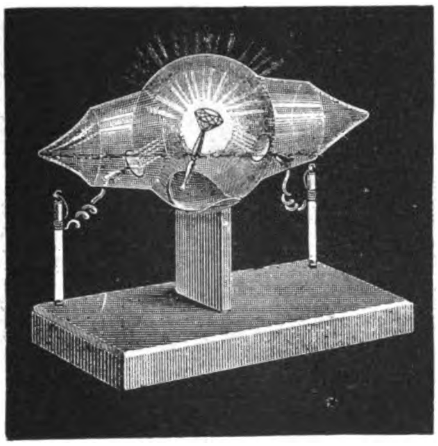

FIG. 3.

small as compared with the dimensions of the bulb, and the properties belonging to the ordinary gaseous state of matter, depending upon constant collisions, can be observed. But in the phenomena now about to be examined, so high is the exhaustion carried that the dark space around the negative pole has widened out till it entirely fills the tube. By great rarefaction the mean free path has become so long that the hits in a given time in comparison to the misses may be disregarded, and the average molecule is now allowed to obey its own motions or laws without interference. The mean free path, in fact, is comparable to the dimensions of the vessel, and we have no longer to deal with a continuous portion of matter, as would be the case were the tubes less highly exhausted, but we must here contemplate the molecules individually. In these highly exhausted vessels the molecules of the gaseous residue are able to dart across the tube with comparatively few collisions, and radiating from the pole with enormous velocity, they assume properties so novel and so characteristic as to entirely justify the application of the term borrowed from Faraday, that of radiant matter.

RADIANT MATTER EXERTS POWERFUL PHOSPHOROGENIC ACTION WHERE IT STRIKES.—I have mentioned that the radiant matter within the dark space excites luminosity where its velocity is arrested by residual gas outside the

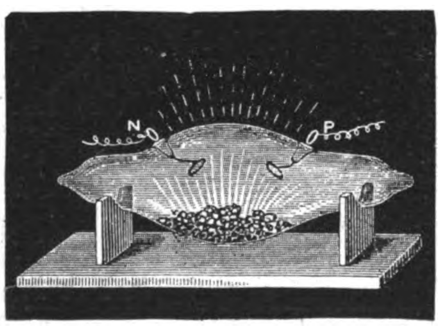

FIG. 4.

dark space. But if no residual gas is left, the molecules will have their velocity arrested by the sides of the glass; and here we come to the first and one of the most noteworthy properties of radiant matter discharged from the negative pole—its power of exciting phosphorescence when it strikes against solid matter. The number of bodies which respond luminously to this molecular bombardment is very great, and the resulting colors are of every variety. Glass, for instance, is highly phosphorescent when exposed to a stream of radiant matter. Here (Fig. 2) are three bulbs composed of different glass: one is uranium glass (a), which phosphoresces of a dark-green color; another is English glass (b), which phosphoresces of a blue color, and the third (c) is soft German glass—of which most of the apparatus before you is made—which phosphoresces of a bright apple-green.

My earlier experiments were almost entirely carried on by the aid of the phosphorescence which glass takes up when it is under the influence of the radiant discharge; but many other substances possess this phosphorescent power in a still higher degree than glass. For instance, here is some of the luminous sulphide of calcium prepared according to M. Ed. Becquerel's description. When the sulphide is exposed to light—even candle light—it phosphoresces for hours with a bluish-white color. It is, however, much more strongly phosphorescent to the molecular discharge in a good vacuum, as you will see when I pass the discharge through this tube.

Other substances besides English, German, and uranium glass, and Becquerel's luminous sulphides, are also phosphorescent. The rare mineral Phenakite (aluminate of glucinum) phosphoresces blue; the mineral Spodumene (a silicate of aluminium and lithium) phosphoresces a rich golden yellow; the emerald gives out a crimson light. But, without exception, the diamond is the most sensitive substance I have yet met for ready and brilliant phosphorescence. Here is a very curious fluorescent diamond, green by daylight, colorless by candle-light. It is mounted in the center of an exhausted bulb (Fig. 3), and the molecular discharge will be directed on it from below upward. On darkening the room you see the diamond shines with as much light as a candle, phosphorescing of a bright green.

Next to the diamond the ruby is one of the most remarkable stones for phosphorescing. In this tube (Fig. 4) is a fine collection of ruby pebbles. As soon as the induction-spark is turned on, you will see these rubies shining with a brilliant rich red tone, as if they were glowing hot. It scarcely matters what color the ruby is, to begin with. In this tube of natural rubies there are stones of all colors—the deep-red and also the pale pink ruby. There are some so pale as to be almost colorless, and some of the highly prized tint of pigeon's blood; but under the same impact of radiant matter they all phosphoresce with about the same color.

Now the ruby is nothing but crystallized alumina with a little coloring matter. In a paper by Ed. Becquerel,[*] published twenty years ago, he describes the appearance of alumina as glowing with a rich red color in the phosphoroscope Here is some precipitated alumina prepared in the most careful manner. It has been heated to whiteness, and you see it also glows under the molecular discharge with the same rich red color.

THE WEEK'S PROGRESS IN SHADOW PHOTOGRAPHY.

SINCE our last issue appeared numerous experimenters have obtained results of more or less interest in shadow photography, both with and without the use of the X-rays emanating from vacuum tubes properly excited, while others have put forth novel ideas as to the utilization of the phenomena made available.

During the week Mr. Edison has continued his experiments and we reproduce in Fig. 1 a cathodograph print illustrating the permeability of thirty substances, numbered as follows, all being as nearly as practicable 1-32 inch thick: (1) iron; (2) brass; (3) lead; (4) tin; (5) antimony; (6) bismuth; (7) cadmium; (8) platinum; (9) copper; (10) aluminum; (11) soft rubber; (12) hard rubber; (13) celluloid; (14) slate; (15) ivory; (16) gelatine; (17) shellac; (18) boric acid; (19) paper; (20) vulcanized fiber; (21) gutta-percha; (22) rosin; (23) stearic acid; (24) asphalt: (25) phonograph cylinder composition; (26) amber; (27) camphor; (28) albumen; (29) glacial phosphoric acid, shellaced; (30) coin silver.

In order to determine whether the rays could be reflected Mr. Edison placed a vacuum bulb in front of the large end of an iron funnel, eight inches long, the small end of which, ¾ inch in diameter, was placed close to the photographic plate. After exposure and development there appeared on the plate two overlapping circular images of the small end of the funnel. Similar experiments with a funnel 9 feet long showed no results, but a general fogging of the plate.

Having in mind the well-known fact that sunlight is fatal to many forms of bacterial disease germs, Mr. Edison proposes to subject various germ cultures to the action of the X-rays.

Since the first announcement of the discovery of Professor Röntgen many photographs have been taken of objects at rest. The fact that baricyanide of platinum phosphoresces in the dark by the action of the X-rays, and also that the light may be seen on both sides of the phosphorescent screen, sug-

[*] "Annales de Chimie et de Physique," third series, vol. lvii., p. 50, 1859.

gested to him that an object would cast its shadow, and thereby form a luminous picture upon paper, prepared with that material. Other experimenters have been reported very recently to have performed similar experiments, among them Professor Salvioni, of Perugia, Italy, of whose experiments we gave a brief account in our last issue. According to a later cable dispatch, Professor Salvioni's apparatus consists of a cylinder of cardboard, the inner surface of which is coated with a material that becomes fluorescent under the action of the Röntgen rays. The lens is at one end of the cylinder. The object to be examined with its coverings is placed between a Crookes tube and the cylinder; on looking into the tube through the lens the observer sees the outline or shadow of the concealed object, which is thrown on the fluorescent interior. The device is still crude, but the inventor expects soon to perfect it. He calls it the cryptoscope.

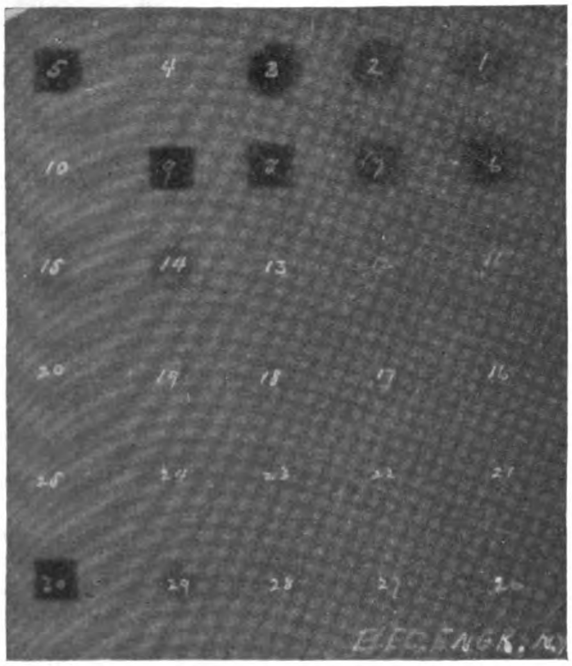

FIG. 1.—CATHODOGRAPH OF 30 DIFFERENT SUBSTANCES.

Mr. E. P. Thompson, of New York, has put forward a scheme for observing shadowy pictures of objects in motion. The details of the proposed apparatus for carrying out the experiment comprises the following elements:

An opaque tube open at one end for the eye to look into and provided with a fluorescing screen at the other, formed by covering a thin piece of white paper with barium platino-cyanide. The object of using white paper or else paper of the same color as the luminous fluorescence is that in addition to the light radiated there may be reflected fluorescent light from the paper itself, the source of light being the film of fluorescent material.

In examining small motions, as, for example, those of the living skeleton of a spider, and in case of a very powerful generator of X-rays giving sufficient light to spare for purposes of refraction, the tube should contain a fluorescent light.

To test this instrument, which may be called a kinetoskotoscope, one looks into the eye aperture, being careful to hold the eye close to exclude all light, and places the object whose motion is to be studied between the other end of the tube and a Crookes tube, all as close together as possible. For small experiments, one looks at the luminous shadow picture, for instance, of a paper-cutter in the process of passing between the leaves of a pamphlet, or the moving wheels of a watch in an aluminum cover.

Professor McGie, of Princeton, is said to be at work on a similar apparatus. Professor Röntgen, in his paper, printed in our last issue, states that the X-rays are not reflected. It is reported, however, that Professors McLellan and Wright, of Toronto University, have succeeded in reflecting and focusing the rays by means of a glass bell jar covering the vacuum tube, and that instantaneous cathodographs can be taken by these focused rays.

LETTERS TO THE EDITOR.

SENSATIONALISM IN THE DAILY PRESS.

Dr. Schuyler S. Wheeler has favored us with a copy of a letter addressed to the New York "Herald," which we print below as originally worded:

"I notice with regret the rush of sensational articles in the daily press in connection with the new cathodography. It is a great pity that much misleading matter is laid before the general public mixed with some that is of profound value and the confusion, loss of respect, etc., which must follow must result in injustice to the profession.

"The articles which have heretofore appeared in the "Herald" upon the subject have been clear, of intense interest and great scientific value, but a day or two ago I saw one of a different character on restoration of life, and to-day a large illustrated article on brain photography, which is not only void of professional dignity and lacking in taste, but bears unmistakable signs perfectly apparent to the serious reader of its real nature. As for the accompanying illustrations of "his own brain," how is it that if the picture is obtained by rays passing through the head the picture is one showing a few surface veins and marks upon the surface of the brain, such as are used to illustrate elementary text books.

"We have and always shall have to suffer a great deal through the public being misled in technical matters by the press, and it would be of inestimable value if you would take the stand of allowing no matter of this kind to appear except after close scrutiny, and let it be known that what appears in the 'Herald' upon such scientific topics has been passed upon and is unquestionable. I believe the New York 'Herald' is most likely to be conservative, and I have therefore taken the occasion to call this to your attention."

ARE THE X-RAYS IDENTICAL WITH DRAPER'S "TITHONIC RAYS"?

I should like to call the attention of those who are investigating the Röntgen rays to the remarkable papers of Dr. J. W. Draper on the so-called "Tithonic Rays," a "class of chemical rays analogous to the rays of dark heat," to which he found writing paper and quartz "far more permeable than the purest plate glass."

Dr. Draper's experiments were made between 1841 and 1844, and will be found in the appendix to his somewhat scarce "Treatise on the Forces Which Produce the Organization of Plants," New York, pp. 144 et seq. (copy can be consulted at my office). They are exceedingly suggestive, especially where he points out that a large number of bodies "obstruct the radiation" of the tithonic rays, so that apparently shadows will remain on a sensitive plate if it be covered by any substance which, while permitting passage to direct rays, will (like glass to radiant heat) obstruct the rays radiated back from the plate. Note also the article on Roric Figures, in Appleton's Cyclopaedia.

PARK BENJAMIN.

New York, Feb. 14, 1896.

MARKS A STEP IN THE RIGHT DIRECTION.

Your account of the work of the New York Edison Company is admirable. It will be a source of much useful information to those engaged in electric lighting business. An electric journal should not confine its pages to things that are new or have the appearance of being new. Old and well-established things which represent the features of the best practice are more important. I, for my part, prefer to read an account of a first-class electric light station than to puzzle over such sensational stuff as seeing without light, light without heat, etheric lighting, wabbling the charge of the earth, etc. I think that "The Electrical Engineer's" issue of Jan. 8 marks a step in the right direction in electrico-technical journalism.

M. I. PUPIN,

Department Electrical Engineering, Columbia College, New York.

THOROUGH AND FULL OF DETAILS.

I really wish to congratulate you upon the recent issues of the "Engineer."

Your description of the Edison stations in New York City was thorough and full of those details that interest practical engineers. I read it quite slowly and carefully and, though I am familiar with Edison station methods, I found many things in that article that were new. Mr. Mavor's series of articles on Concentric Wiring were full of interest and your Patent Office articles by Mr. Dodge are well worth reading.

A. E. DOBBS.

CONTENTS.

SHADOW PHOTOGRAPHY.

ONE would have thought that all possibilities in the production of cathodographs, or, speaking more broadly, shadow photographs, had been exhausted, but each succeeding day brings forth new ideas or conceits, some of evident promise, but not a few of more than doubtful character. Touching for the present upon the former, the work of more recent experimenters appears to be largely concentrated on methods of obtaining these curious effects by means other than the rays emanating from vacuum tubes. We have already chronicled some important results obtained in this line of research, and to these we add this week another contribution by Mr. J. H. Robertson, who has succeeded in securing a shadow photograph by means of the arc light, pure and simple. Leaving out of consideration the theory put forward by Mr. Robertson to account for the phenomenon, it may be fairly assumed that the fact is established that some of the rays emanating from the arc light penetrate opaque substances and are capable of affecting a sensitized photographic plate. Indeed, a recent experiment is recorded in which a similar effect was obtained with ordinary sunlight after extended exposure. At the first blush such a proposition might be negatived by pointing out, as Professor Elihu Thomson did in a recent issue of "The Electrical Engineer," that if direct sunlight affected photographic plates it would be impossible to keep them unfogged. But, on the other hand, there is corroborative evidence to be found in the vagaries which photographers not infrequently encounter upon developing plates, and which have never been satisfactorily explained. Apropos of this aspect of the question is the interesting letter by Dr. Park Benjamin, which appears on another page, in which that erudite writer points out the similarity in some respects of the X-rays, and the "tithonic" rays of Dr. Draper, studied by him as far back as 1844.

One of the most interesting of the side paths opened up by Röntgen's discovery is the possibility it holds out for observing objects in the dark. Several experimenters have already begun work on this branch, which also seems to have been anticipated in a remarkable way by Mr. Georges d'Infreville, who, it will be remembered, in a recent issue of "The Electrical Engineer" stated in general terms the manner in which such a scheme could be carried out. The recent publication of similar ideas by others has now relieved Mr. d'Infreville of the necessity of maintaining silence on his methods, which he now fully describes on another page. The project itself is entirely correct in theory and has already been shown to be feasible in practice. Just to what extent the process can be utilized in the arts and sciences remains to be seen; but that it is of unquestioned value must be apparent.

Thus far the application of shadow photography seems to have been confined almost exclusively to surgery and medicine; but we are glad to know that an attempt has been made to employ the process at the Carnegie steel works for the purpose of examining iron structures, and, though the first results obtained, we understand, were not encouraging, it is to be hoped they will be continued. It has also been suggested that the process might be employed for the purpose of discovering bad work, such as imperfect joints in electric wiring. We do not imagine that the taking of cathodographs after the work is finished will take the place of the watchful eye of the foreman or insurance inspector, but that the cathodographic process may be applied to the examination of a variety of electrical

work seems quite probable. In view of the relationship which exists between the X-rays and the radiant matter of Professor Crookes, we have thought that our readers might desire an authentic statement on the latter, and have therefore reproduced Professor Crookes' lecture of 1879.

While the zeal with which this whole subject has been taken up by electricians and physicists in general is most commendable, we cannot refrain from expressing our regrets at the manner in which the discovery and its applications have been treated in the daily press. It is well within the province of the latter to keep the public informed of the latest progress in science as well as of the developments in the latest murder case, but unfortunately not a few of our daily contemporaries have allowed the imaginations of their reporters to run riot, with the consequence that much of the good effect which the discovery might have produced in elevating science in the public mind has been destroyed and given place to doubts and to incredulous shakings of the head. That we are not alone in thus deploring this state of affairs is manifested by the letter addressed by Dr. S. S. Wheeler to one of our daily contemporaries, which we reproduce in another column. Perhaps, however, we may be too severe on the daily press, and it may be barely possible that the workers in this new field may themselves be responsible to some extent for some of the hare-brained schemes to which the new discovery has been alleged to be applicable. There is enough that is good and valuable in the discovery, however, to make it outlive any temporary set-back which it may have received at the hands of the lay press; and when the popular excitement has died down we may hope to hear of the beginning of real progress in the study and application of the X-rays.

THE ZURN BILL BEFORE THE NEW YORK LEGISLATURE.

IT has become one of the favorite pastimes for the average legislator to pose as the champion of the people in the curtailing of the powers of companies operating under municipal franchises. The latest instance of this kind is to be found in the Zurn bill, now before the New York legislature, the object of which is to reduce the price of electric lighting in New York and Brooklyn. This bill, which was before the Assembly Committee on Electricity, Gas and Water Supply, contains the following clause:

It shall not be lawful for any company or companies organized to supply electric lights in cities of this state having a population of 800,000 or over to charge more than three-fourths of a cent per light per hour for each incandescent light, nor more than 4 cents per hour per light for each arc light.

According to Mr. Zurn, in New York City gas sells for $1.25 per 1,000 feet, giving with a five-foot burner 200 lights of sixteen candle power. The same amount of light by incandescent electric lights would cost $2.40. The question, therefore was reduced to cost of production, and it remained for electric light companies to show they could not produce the same amount of light from a ton of coal as could the gas companies and produce the same as cheaply. If they were not doing so it did not follow they could not do so, for it was a well-known fact that many electric lighting companies were confined to the use of devices which were not the best in the market nor the most economical in their operation. The public, argues Mr. Zurn, should not be compelled to shoulder the expense of bad management, faulty engineering, or any of the sins of omission or commission of the companies or the persons who manipulate them; it was obviously no more than just that the electric lighting companies, as light dispensers and sellers, should be governed by the same law which holds with other light producers and dispensers, and, as light could be measured as readily as any other article of merchandise, it followed that it might be rated at a certain value, whether produced by gas or electricity. There were means for determining the amount of light given at any specified point, and, as with heat, the price depended upon the two factors, time and quantity. Let the electric light people face the issue of cost of production, and face the conclusions which must be the logical outcome of their position!

The logic of Mr. Zurn's arguments is little short of ludicrous, and the bill itself would be scarcely worthy of serious consideration were the measure itself not being actively pushed in the State Legislature. To argue that the same amount of electric light ought to be produceable from a ton of coal as can be got from gas with the same amount of fuel is sufficient to show the absolute worthlessness of the facts offered in substantiation of the Zurn bill. But conceding even some of the contentions of Mr. Zurn, the fact remains that the large consumers in New York City are to-day paying no more for electric lighting than they would for an equivalent amount of lighting by gas. That the small consumer has not yet been placed on the same advantageous level is certainly not the fault of the electric lighting companies, who have steadily reduced their prices and who have always been willing, to our knowledge, to give their customers the benefit of all the improvements which have been made in the art. It seems little short of barbarism to put the pioneer companies who have spent hundreds of thousands of dollars in developing a new art to the expense of discarding all their old apparatus the instant an improvement in detail makes its appearance. Yet even on this alleged dereliction on the part of the companies, Mr. Zurn seems to be lamentably misinformed. Any one who has followed the history of the electric lighting companies in New York and Brooklyn must know that they have kept in the vanguard of progress in all that relates to the cheap generation and distribution of current; and it is due to this very fact that they have been able to produce and distribute current at the prices at which they are doing at the present time. Perhaps if Mr. Zurn had had a chance to read the recent description of the Edison stations in New York City which appeared in one of our January numbers, and contemplated the enormous investment of capital required to reach the perfection everywhere exhibited, the bill bearing his name might not have seen daylight. What makes the bill still more absurd on its face is its limitation to cities above 800,000 inhabitants. The merest tyro in central station finance could have shown that in just these very cities the cost of generation and distribution of electric current in which conductors are, by law, compelled to be carried underground, and in which all manner of restrictions are placed upon the companies by the local authorities, far exceeds that met with in smaller towns, so that, if for no other reason, a reduction of income would be a particular hardship on the companies located in such cities. Up to our going to press no action had been taken on the bill, and it is to be hoped that none will be. While affecting, it is true, only the cities of New York and Brooklyn, the principle involved is a broad one and ought to have the earnest attention of the New York State Electric Lighting Association.

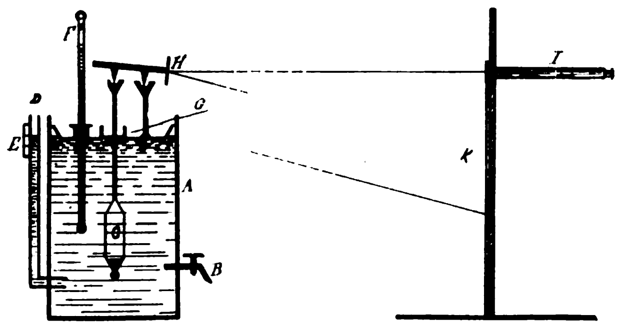
MISCELLANEOUS.

A SUGGESTION FOR SHOWING MINUTE CHANGES IN THE DENSITY OF LIQUIDS.

BY NEVIL MONROE HOPKINS.

WITH the apparatus shown in the accompanying sketch some interesting determinations in the specific gravity of liquids can be made. A is a tin reservoir with a cock, B, for bringing the fluids to be determined to constant level, which may be shown by the scale E on the gauge.

The float G consists of a circular pan or dish of metal with a tube opening for a thermometer (F) and a hydrometer (C). The stem of the hydrometer should be of very small diameter for delicate work, as it rises and falls through greater distance for a given change in density than a coarse stem. The top of the hydrometer stem carries the little bearing which supports one end of the aluminum beam, carrying the little mir-



A SENSITIVE HYDROMETER METHOD.

ror (H), the other end of the beam being supported by the standard on the float. The little beam with its knife edges keeps the hydrometer in the centre of the opening in the float and prevents any error which would be caused by the friction of contact. A stand and scale with the telescope (I) attached completes the apparatus.

The change in densities of liquids due to temperature changes can readily be observed and solutions of salts accurately compared. To use the galvanometer expression, the readings are nearly "dead beat." It will be readily seen that a hydrometer of this delicacy is limited to only the smallest changes. Could such a mirror device be connected with a storage battery, when at work, the behavior and changes in specific gravity of the acid could be closely observed.

PRESSURE AND CONDUCTIVITY.

An article by Gustav Tammann in "Zeit. Physikal. Chem." is summarized in the Journal of the Chemical Society: The influence of pressure on conductivity may be divided into three factors; (1) volume alteration; (2) alteration of viscosity and ion friction; (3) alteration of the degree of dissociation. The effect of pressure on viscosity has been determined by Cohen for sodium chloride solutions; the viscosity of solutions of small internal pressure diminishes with increase of pressure, the reverse obtaining with solutions of high internal pressure. The effect on the dissociation constant is given in a table of percentage alteration due to pressure of 500 atmospheres for solutions of varying concentration and dissociation. The total effect is then considered and typical curves are given. With infinite dilution, factors 1 and 2 alone are weighty, and these cause an increase of about 4.5 per cent. (for 500 atmos.). If the concentration increases, there are three types of curves: (I) where the electrolyte is feebly dissociated, the curve rises to a maximum and slowly falls; (II) where the dissociation is great and factor 3 of small account, the curve is at first almost parallel to the axis of concentration, then slowly sinks, owing to the effect of the viscosity, and finally cuts the axis; (III) for intermediate dissociation, the rise is not as rapid as in (I), and a well-marked maximum occurs. The curve is also given in the case of sulphuric acid, which is shortly considered; a maximum occurs here at concentration 0.5 per cent. and a minimum at 85 per cent.

ELECTRIC HEATING—I.

BY W. S. HADAWAY, JR. NEW YORK.

THE term "electric heating" is commonly used to express the frittering down of the high potential energy of electricity into the lower potential energy of heat. There is no well defined line of demarcation; the resultant is inseparable from the conveyance or utilization of electricity in any degree. The term is therefore a meaningless one from the heat engineer's standpoint, and it fails to accurately express the performance of useful work by the transmission of heat energy to a distance by means of electricity. The expression "electricity as a factor in a telethermal system" would be a better definition of the subject-matter of this paper, but for obvious reasons the shorter and simpler term is employed.

We are to regard heat energy as a commodity that can be generated or controlled in convenient form and distributed and sold, and in which electricity is used either directly as the high potential heat factor or indirectly as agent. The distribution and application of heat energy by electricity to arc and incandescent lighting, to metal welding and forging, and in the Cowles and Acheson furnaces are illustrations of results already attained in electric heating, and are properly discussed under the broad interpretation of our subject. The feature of the subject that we are to consider here is the practical adaptability of commercial electricity for heating purposes and for performing useful work under the conditions imposed in general industrial and domestic life, outside of the specific adaptations previously mentioned, and particularly in connection with other heat distributors for a multi-potential heat supply.

These applications may be roughly divided into two classes, according to the degree of concentration of the heat energy used, the first including low temperature heating, generally diffused and in large volume, and the second including high temperature heating, generally localized and in small quantity. In heating on a small scale no adequate classification is possible; it is the shading of high potential heat energy into low potential heat work for many useful operations that primarily suggests the feasibility of heat transmission by electricity. The arbitrary line of temperature demarcation for heating on a large scale is here drawn at 250 degrees F. The closest common analogy to the differences between low potential large volume and high potential small volume heating is the distinction between volume and pitch in sound. As examples of the first class may be cited the heating of rooms and of water under atmospheric pressure; examples of the second class, are oven, sad iron, and soldering iron heating.

The electrical horse power hour is the equivalent of 2544.6 British thermal units. For practical purposes the work in hand is to determine the useful work in different lines obtainable from this number of heat units at a fair average cost of supply; it involves, indirectly, determinations of relative efficiency between electric and common methods of heat generation, distribution, and application.

To show what the heating efficiency of different methods of application may mean, the following experiments, reviewed in the London "Electrician" for November 2, 1894, are cited: the determinations were the relative heating value of combustion and electricity by resistance. The same wires were heated first in a flame and then by electric current. It was found that with a platinum wire held in the flame less than 0.5 per cent. of the thermal energy produced in the flame was transferred to the wire, while 90 per cent. of the electrical energy used appeared as heat.

In another case an iron bar weighing about 20 pounds was heated by charcoal and then by electricity; in the former case about 0.75 per cent. of the thermal energy was transferred to the bar and in the latter case 88 per cent. It is evident from the description that the calorimetric methods employed were rough, and the results are quoted more as qualitative than quantitative determinations. It should be observed that the foregoing illustrations are examples of our second class of heating. Figures obtained from tests made on energy required to heat one gallon of water by various methods of heat application show that there are wide differences in efficiency in our first class of heating. The heat capacity of the work performed was sufficiently large to express the relative differences in impartivity, and as we should expect, the lower the temperature of the work the larger the area heated, and the greater the capacity the less the difference in ratio between heating

1 Abstract of paper read before the Am. Society of Heating and Ventilation.

by combustion and by electricity, and we can easily determine the conditions when the ratio is an inverse one.

In room heating apparatus on continuous run we may figure that one watt, 3.4 thermal units, will heat one square foot of common radiator surface through 1.35 degrees F., and that 100 watts, or 340 thermal units, will heat the surface approximately 135 degrees F. above the room temperature. That is, for room heating, 100 watts are practically the equivalent of steam at low pressure condensed by one square foot of radiator surface with the difference between the room and the radiator temperatures as above stated. This, of course, takes no account of the heat capacity of the apparatus, which is practically eliminated by the condition imposed of continuous running.

We may safely assume that a fair average price of the horse power hour from large steam electric stations is five cents. It would therefore cost 0.67 cent to run one square foot of direct radiator surface for one hour, or the electrical horse power would keep about 7.5 square feet of radiator surface at the temperature differences noted for one hour. For direct comparison with a central station low potential heat distributor, we may compare this cost with figures of charges made by the New York Steam Company as quoted by Unwin in his treatise on "The Development and Transmission of Power." The unit of heat used by the New York Steam Company is stated to be the "kal," which is defined as the heat required to evaporate one pound of water from 100 degrees F. into steam at 316 degrees F. or at 70 pounds pressure per square inch. One kal is therefore about 1,110 thermal units. On a sliding scale the charge is stated to be 70 cents per 1,000 kals to small customers and 40 cents per 1,000 to large users. As the price of five cents per horse power hour is to a large user we will compare it with the 40 cents per 1,000 kal rate. For 40 cents the consumer secures 1,110,000 thermal units from the steam station compared with 20,518 thermal units from the electric station, a ratio of nearly 54 to 1, or practically 50 to 1, as a loss must be figured in the case of steam, dependent upon the temperature at which the condensed water is allowed to escape.

It is interesting to note in passing that while the relative generative efficiencies are about as eleven to one, the commercial rates are as fifty to one. The ratio of the cost of heat energy from the electric station to the cost from the steam station is therefore practically four times as great as the ratio of the relative costs of production. This fact should be borne in mind in discussing Crompton's paper on Electric Energy, in which the influence and importance of the "load factor" is pointed out.

Clearly the steam electric light station ranks low as a heat distributor for house warming on a large scale. Notwithstanding the great disparities in the cost of heat energy on a large scale, the uses to which small electric air heaters are put are surprisingly numerous. We are all more or less familiar with the use of gas stoves for room warming; it is found by experience that the electric air heater for auxiliary room warming, for bath and dressing rooms, for libraries, cabins on yachts and steamships, in mild climates, in early morning and evening, etc., serves its purpose economically and effectively. It is then, on a comparatively small scale and in intermittent service that the electric air heater is useful when power is derived from the steam electric station and when the heat supplied is derived from electric resistance.

While considering the use of electricity in diffused heating on a large scale, we should not overlook the deductions made by Lord Kelvin "On the Economy of the Heating or Cooling of Buildings by Means of Currents of Air" and published in the Glasgow Philosophical Proceedings, Vol. III, December, 1852, and followed by mathematical demonstrations in the Cambridge and Dublin Mathematical Journal for November, 1853. Quoting from these articles:

"In the mathematical investigation, it is shown that according to the general principles of the dynamical theory of heat, any substance may be heated 30 degrees above the atmospheric temperature by means of a properly contrived machine driven by an agent spending not more than about 1-35 of the energy of the heat thus communicated; and that a corresponding machine, or the same machine worked backwards, may be employed to produce cooling effects, requiring about the same expenditure of energy in working it to cool the same substance through a similar range of temperature. When a body is heated by such means about 34-35 of the heat is drawn from surrounding objects and 1-35 is created by the action of the agent; and when a body is cooled by the corresponding process the whole heat abstracted from it, together with a quantity created by the agent, equal to about 1-35 of this amount, is given out to the surrounding objects."

We have thus introduced refrigeration as well as heating by electricity as agent. In editing his Mathematical and Physical Papers, Lord Kelvin added the following interesting note under the date of June 26, 1881:

"The method of cooling air in unlimited quantities described in this article has been realized by Mr. Coleman, first in refrigerators used for the distillation of paraffine, and after that in the Bell-Coleman refrigerator for carrying supplies of fresh meat from North America to Europe, in a great refrigerator recently sent out for the abattoir at Brisbane, Queensland. The Bell-Coleman machine sends large quantities of air, cooled to 10 to 20 degrees C. below the freezing point, into the chamber to be kept cool, and the general temperature of this chamber is thus maintained at the desired point.

"The method of heating air described in the article remains unrealized to this day. When Niagara is set to work for the benefit of North America, through electric conductors, it will, no doubt, be largely employed for the warming of houses over a considerable part of Canada and the United States. But it is probable that it will also have application, though less large in other cold countries, to multiply the heat of coal and other fuels, and to utilize wind and water power (with aid of electric accumulators) for warming houses."

In Anderson's treatise on the Conversion of Heat into Work, third edition, pp. 189 and 194, will be found descriptions of compressed air refrigerating machines made on the principle above described, and in Prof. Peabody's work on the Thermodynamics of the Steam Engine, pp. 464 and 465, will be found tests on a Bell-Coleman refrigerating machine. The use of electric motors in refrigeration has already received consideration of central station men, having been advocated by well-known engineering authorities, but so far as I can learn nothing whatever has been accomplished in the use of motors for heating purposes.

When electricity is derived from water power we might expect a far wider availability of energy from heat of resistance for house warming than when electricity is derived from steam power. Careful deductions show that the cost of the horse power year must not exceed $6 in order to compete directly with good coal at $5 per ton for house warming in this latitude. The statistics of Prof. Swain show that the average cost of the mechanical horse power year from water power in this country is about $10; to this we must add electrical generation and transmission charges, making it seemingly impossible to realize a figure for electrical energy delivered that will not be three or four times the cost of heat directly from coal. In the Niagara power transmission scheme, I understand it is contemplated selling the electrical horse power year for $20. At this rate it may well be questioned whether there are not sufficient compensating advantages in regulation and control to warrant the very extensive use of the heat of resistance for house warming at least, and we are aided in this direction by requiring a lesser maximum capacity of the apparatus, as the heaters may be run night and day without additional cost within restricted areas. There are water power plants in the West where, with large falls, the cost of the horse power year is very low. In these places there will undoubtedly be many expensive applications of room heating on a successful basis.

In his paper on "The Cost of Steam Power," Trans. Am. Soc. of Electrical Engineers, March, 1893, Mr. C. E. Emery cites the cost at Lawrence, where, with moderate fall, the cost of the horse power year from water power is figured at about $25, or practically the same as power generated from steam. We thus see that in the practical treatment of this question local conditions will control the breadth of applicability, including in these local conditions prime cost of electric power, cost of coal delivered, extremes of climate, average humidity, etc.

We have still another source of electrical energy to consider in connection with low temperature diffused heating in which power is derived from gas, oil, and air engines. Prof. Kennedy, in a lecture before the Royal Institution in April, 1893, on the "Utilization of Energy," places the theoretical efficiency of coal gas at 80 per cent. Of this a gas engine, he says, utilizes from 22 to 32 per cent. For diffused heating it is apparently more economical to distribute the gas than to attempt to convert it into kinetic energy and transmit it by electricity. In this connection I would call attention to Mr. Williams' paper before the Society of Arts, Boston, May 10, 1894, in which comparative costs of coal and various fuel gases are given, and in which it is shown that the gas equivalent of coal may, under most favorable circumstances, cost eight or ten times as much as coal.

The consideration of the relative values of gas and electricity for heating purposes is a matter which can only be inadequately discussed here, for the problem is a complicated one and demands the most thorough consideration. No one can underrate the facility of storage of gas, the economy of rapid and continuous generation, available heat from combustion, and discharge of by-products, whereas in electric lighting and electric heating every unit of light or heat secured represents an appreciable loss or depreciation of the energy converter. There are many advantages to be considered on the other side, such

as localization, immersion of heater in working chamber, as in ovens, sad-irons, and water heaters, freedom from by-products, etc. In electric heating for domestic use, as in the use of gas for the same purpose, the bête noir of the situation is how to provide the hot water supply economically. It seems easier to arrange for this on a multi-potential heat supply system than on any system using gas, unless the heat wasted in gas manufacture can be stored and utilized.

In his treatise on Gas Engines, Donkin shows examples of gas engines of considerable size, furnishing power at rates less than can be secured from other prime movers. A case has come to my attention of a gasoline engine supplying energy at the dynamo terminals at a cost slightly under one cent per horse power hour. For high potential heat distribution from isolated plants this form of energy transmitter is generally available; but it may be seriously questioned whether, in isolated plants for domestic use, the hot water supply as commonly provided can be economically heated.

We may safely conclude from the foregoing illustrations that we cannot afford to use high potential kinetic energy for general diffused heating purposes on a large scale. The thermal unit is the equivalent of 778 foot pounds of work, and we would secure as much heat by applying a brake directly to the fly-wheel of the engine or prime mover as we obtain from the heat of electrical resistance which, so far as its results go, may be considered as friction. One pound of good coal has a potential heat energy as great as 5 7-10 horse power hours.

If we use as an average thermal value of the pound of coal 14,500 units, we can secure 9,400 units in a good boiler, or practically 65 per cent. There are many cases in practice in which this efficiency is exceeded, but Thurston's figures give 65 per cent. as a fair average value. The fuel efficiency of the steam engine rarely exceeds ten per cent., and the heat incapable of conversion into high potential energy represents about nine-tenths of the whole, notwithstanding the fact that over six-tenths of the thermal energy of the coal is secured in useful work in the boiler.

It is therefore to this point we must look for our large volume heat supply, and we find in actual practice many illustrations which show that no great engineering difficulties are encountered in distributing the boiler energy, and also that of the exhaust steam from the engine, for useful work at a distance.

The New York Steam Company's plants already referred to are distributing energy by live steam for heating and power purposes at about 80 pounds pressure, the pressure differing, however, in the uptown and down-town stations. The leakage and radiation losses are stated to be estimated at about 15 per cent., yet with this loss the heat energy can be delivered on a very economical and successful basis.

The work of Birdsill Holly since 1877 in carrying out central station heat supply is too well known to require comment. It is important and interesting in connection with our problem, since it shows that central station diffused heat supply is entirely feasible. We are now able to formulate a multi-potential heat supply system in which the steam, either live or exhaust or both, is used for low temperature work, and electricity from generators in the same station is employed for all work requiring temperatures in excess of that of the steam; i. e., from about 250 degrees F. upwards.

In domestic work the steam heat would be employed for house heating and water heating for bathing and culinary purposes. Electric heat would be used for lamps, ovens, broilers, small portable stoves, sad-irons, curling irons, and all purposes requiring a high temperature localized heat. And a feature of such a combination not to be overlooked is the facility with which ventilation and heat regulation can be secured, since all the elements are at command to force an abundant supply of heated pure air through the building to be warmed.

There are no new or untried features in such a combination; practically all the elements necessary for the work are already employed, though in a somewhat disjointed form as far as complete flexibility of heat supply from one center of distribution is concerned. In the "Electrical Engineer" for April 5, 1893, will be found a description of the Springfield (Ill.) electric light and steam distribution plant. In operating this plant the exhaust steam is used for warming buildings, but so far as I am aware no systematic attempt has been made to carry out a multi-potential heat supply. The revenue from building heating, I am informed, was over $12,000 during 1894, which is largely clear gain, considering it from the standpoint of the common electric light station, barring of course the fixed charges for the extra equipment. An instance occurred in Boston of a small, centrally located electric light station paying its expenses by the sale of steam for heating purposes.

CONTEMPORARY ELECTRICAL SCIENCE.

"Wiedemann's Annalen" for January contains many somewhat startling contributions. Electric waves are, as usual, the staple product of German-speaking physicists, although Boltzmann and Planck deliver two separate attacks upon modern "energetics," chiefly as expounded by Ostwald. It seems that the mechanical theory of the universe and scientific materialism, so ably attacked by the great chemist, will not surrender without a struggle. Planck himself also writes upon the reasonance of electric waves, and shows how the distribution of energy in a resonating circuit may be calculated from Maxwell's equations. Elster and Geitel contradict the rumor that positive electricity is dissipated, like negative, by the action of light. They show that it is all due to a secondary action upon the platinum cathode as soon as it gets coated with a layer of vapor from the liquid sodium-potassium alloy forming the anode. V. von Lang has an interesting little paper upon "The Diminution of Resistance of a Light Contact Between Carbons or Metallic Terminals" under the action of the slight electric waves produced by an electric gas lighter or by an electrophorus. The experiment with carbon is easy, but that with metals requires great care in order to avoid the slightest concussion. Leo Arons discusses the curious fact that "Alternate-Current Arcs" are much more difficult to produce with metallic than with carbon electrodes, and suggests three possible explanations. The carbon may be better suited to sustain the necessary heat through the zero points, owing to its smaller thermal conductivity. Or the gases which carbon always will evolve up to its own death, in spite of all precautions, may undertake this function. Or the metallic oxides are in the way. Perhaps further experiments will bring more light.—London "Electrician."

SOME HINTS TO INVESTIGATORS OF SPARK SPECTRA.

At the present time, when attention is keenly directed to the subject of spark spectra, it may be desirable, for such as are interested, to study a recent paper by A. de Gramont on the direct spectrum analysis of minerals and fused salts (vide "Comptes Rendus," cxxi., pp. 121-123). Many of the minerals have sufficient conductivity or volatility to permit the passage of a condensed electric spark between the small fragments of the mineral attached to the pole of the coil. With a condensed spark the spectrum shows the lines both of the metals and of the non-metals present in the mineral; without the condenser, the spectra of the non-metals disappear, and those of the metals show only the brightest lines. Certain fused salts behave in a similar way, and when the condensed spark is used, the spectrum contains the lines of all the elements present, together with some air lines, which, however, are much enfeebled, especially if the striking distance is short. Without the condenser, the spectra are complex, and characteristic of each particular salt. De Gramont suggests that such spectra are probably produced by undissociated molecules.

THE ELECTRICAL CONDUCTIVITY OF ALUMINUM.

In an article appearing in the London "Electrical Review," Mr. G. L. Addenbrooke announces that, according to researches of Lord Kelvin, the conductivity of pure aluminum is 68.5 per cent. of that of pure copper. The usual conductivity, as given in the books, hitherto has been 56 per cent. that of copper. Lord Kelvin's research has, therefore, raised this by 21 per cent., so that the conductivity of a wire of pure aluminum of the same section instead of being a little over a half that of a copper wire of similar section, is more than two-thirds the conductivity. Consequently, the diameter of an aluminum wire of the same conductivity as a given copper wire will be only 15 per cent. greater, or less than one-sixth greater than that of the copper wire. This is a small fraction, and it is evident that for such a small increase of diameter the extra cost of insulating aluminum conductors to the same thickness as copper ones, and to secure the same conductivity, will present no serious obstacle.

Looked at in another light, copper is about 3.3 times the weight of aluminum; on Lord Kelvin's figures the conductivity of wire of equal weights of copper and aluminum will therefore be as 100 : 22.6, so that the weight of an aluminum wire of the same conductivity as a copper one would be four-ninths of the latter, or considerably less than one-half.

It would be difficult to say what extra cost would be entailed in manufacturing aluminum of this purity, but it may be assumed that before long the resources of metallurgy will be equal to it at a moderate cost.

As aluminum is just as pliable and easy to work as copper, it goes without saying what an advantage it would be in constructing heavy cables, and how much less strain on the insulating material it would impose. For overhead conductors for the supply of power the advantages of obtaining a conductor of equal conductivity with a trifling increase in diameter and of half the weight are also manifest.

As a conductor aluminum is now about twice as costly as copper, but as by the electrolytic process the price has already been reduced in eight years from 90 cents per ounce to 35 cents per pound, it is abundantly clear that with the inevitable improvements which are taking place the difference in price between aluminum and copper, which still exists, will be more than obliterated before long.

THE CENTRAL STATION INDUSTRY IN FRANCE.

In a recent issue "L'Industrie Electrique" publishes the sixth edition of its provincial central station table. In January, 1895, France, exclusive of Paris, possessed 328 electric supply stations; to-day the total is 438. The increase in the total horse-power has not, however, been very great; the figures for the 378 stations which sent in returns showing a total of 47,712 h. p. (126 h. p. per station), as against 39,420 for the 328 stations at work last January. The 378 stations may be classified as follows:

Motive Power—	No. of Stations.	H. P.
Hydraulic	182	11,665
Hydraulic and steam	48	7,422
Steam	128	26,802
Producer gas	6	206
Town gas	13	1,605
Petroleum	1	12
	372	47,712

System—	No. of Stations.	H. P.
Continuous	293	31,935
Alternate	75	14,927
Polyphase	4	850
	372	47,712

"LITTELL'S LIVING AGE."

The January issues of "Littell's Living Age" contain many papers of more than usual interest and value. Among others may be mentioned "Lord Salisbury," by Augustin Dilon; "Mathew Arnold in His Letters," by Alfred Austin; "Kashmir," by Sir Lepel Griffin; "The Air Car, or Man-lifting Kite," by Lieut. B. Baden Powell; "Corea and the Siberian Railway;" "Muscat," by Theodore Bent; "In the Wild West of China," by Alicia Bewicke Little. "1920," from the "Contemporary Review," is a thoughtful forecast of the future growth and importance in the world of the Anglican race, and furnishes much food for thought. Other articles worthy of prominent notice are "The Peasant Life of South Russia," from Blackwood; "Purcell and the Making of Musical England," by Frederick J. Crowest; "William Blake," by Alfred T. Story; "Fighting Thurlow, His Foes and Friends," by W. P. Courtney; "The Lost Ambassador," by Margaret Howitt; "Recollections of Thomas Carlyle," with many others of scarcely less value. Fiction is well represented by short stories from the pens of M. B. Hardie, John Habberton, I. Hooper, etc. A page of the best current poetry accompanies each number The above partial table of contents of one month's issues bears witness to the fact that the recent reduction in price from $8 to $6 does not mean any lowering of the value, or any falling off from the high standard this magazine has hitherto maintained. The busy men and women of today, who demand the best that the literary field can supply, will find "The Living Age" as fresh, timely, and indispensable as ever. Littell & Co., Boston, are the publishers.

SOME FACTS ABOUT ACETYLENE GAS.[1]

BY JOHN C. MC MYNN, M. E.

ACETYLENE gas has been known for many years as a laboratory product too expensive for anything but experimental use. A possible method of producing this gas on a commercial basis was developed in the electric furnaces of the Wilson Aluminum Company, at Spray, North Carolina, by Mr. T. L. Wilson while experimenting with the production of aluminum and the smelting of other very refractory substances, such as lime, silica, calcium, etc., under the direction of Major J. T. Morehead, the President of the Company and a geologist of reputation. Experiments were being conducted with a view of combining the metal calcium with other metals, and in the course of such experiments lime and coke were fused together and the resulting product thrown into water, when it produced a violent bubbling by giving off a gas which, when lighted, gave an intensely brilliant flame. A long series of experiments followed, made by Dr. De Clalenot and Major Morehead, to determine the correct proportions of lime and coke, together with the analysis of all mixtures and resulting products.

In a recent visit to Spray, North Carolina, I found a very primitive electric furnace, the current for which is furnished by two 120 K. W. alternators. The voltage is transformed down to about 100; the carbons are twelve inches by eight inches, and 36 inches long, and with between 1,300 and 1,400 amperes the brilliancy and intense heat produced can hardly be imagined unless seen. Finely powdered coke and crushed lime are thrown between the carbons and fused in the intense heat, which results in the production of calcium carbide. This is a black crystalline substance, very hard and insensible to heat, but when placed in water produces a carbon vapor, through the chemical combination of two parts of carbon with two parts of hydrogen, and which possesses the highest illuminating power of any known gas. The calcium combines with the oxygen of the water, thus making a double decomposition.

A company has formed to develop its production and to sell rights for its manufacture. The new product has been the target for all the usual criticisms, and such papers as the New York Tribune and the Engineering and Mining Journal in recent issues have asserted that there was never a ton produced in this country, and if there were it would have cost over $100 per ton. These statements can only be excused through a biased determination to oppose any new process, or a disinclination to investigate both sides of a question. That the new gas will be a rival to electricity cannot be denied, and as owners and managers of electric lighting plants it behooves the members of this association to invesugate the subject for themselves and to decide as to its value as an opponent to not only the incandescent, but the arc light, and not to take the advice of such electrical papers as are too cowardly to state the truth, or too lazy to investigate. While at Spray every facility was given me to fully examine the plant and to make measurements of all factors entering into its manufacture. I regret that at this time I cannot make my report public, but I can state most emphatically that while I was there two tons of calcium carbide was produced in two days and at a cost of about $25 per ton. Samples of this carbide produced an average of 5.13 cubic feet of acetylene gas per pound of carbide. The methods used at Spray can be improved upon by any one building a new plant and many of the losses eliminated.

In regard to its use as an illuminant, acetylene gas when burned in a tip using one cubic foot per hour will produce about 50 candle power, but the flame, which is a solid flame, having no blue portion near the burner, seems to diffuse much more than this amount of light, because of the fact that its spectrum is nearly identical with that of the sun. A one-half cubic foot tip will give a flame that is ample for all purposes of house lighting, and these tips will be most generally used. Admitting that these tips will replace the common 4 or 5 cubic foot tips, we would have one-half cubic foot, giving more light than 4 cubic feet of common gas. Or 1,000 cubic feet of acetylene giving more light than 8,000 cubic feet of ordinary gas.

The average price for gas in the six plants in Southern Wisconsin is $1.76 per 1,000 cubic feet; hence the corresponding price for acetylene gas would be $14.08 per 1,000 cubic feet. That is, acetylene gas could give the same amount of light per 1,000 cubic feet for this price. But the fact is that this gas can be produced at any suitable electric plant in Southern Wisconsin for a miximum figure of $5 per 1,000 cubic feet.

The gas can be used in several ways.

First.—Distribution through mains is not the most advisable method since leakage would be a large factor and the original investment large.

Second.—The carbide can be distributed to residences and a small automatic generator placed in the basement, in which a week's supply could be stored. A house having 20 burners would probably use 10 burners for about 4 hours per day, and with one-half cubic foot tips would consume 140 cubic feet of gas per week, or about 28 pounds of calcium carbide, at a cost of 3 cents per pound. This would give a gas bill of $3.36 per month, and the house would be much more brilliantly lighted than it could be in any other way except by a larger number of incandescent lights.

Third.—A valuable property of the gas is that it will liquefy

1. A paper read before the Northwestern Electrical Association, at Milwaukee, Jan. 17 19.

itself if the resulting gas is contained when water is added. This liquid gas is to be distributed in cylinders similar to carbonic acid gas cylinders (as used for soda water fountains), and when admitted to the house mains through pressure-reducing valves, it assumes all its gaseous qualities. I am at present investigating the liquefaction process and will publish the results of my experiments.

To sum up the situation from an electrical standpoint: This is a new gas having an illuminating power much greater than common gas. No investment for street mains is necessary, hence the gas companies must use it either as an enricher or as an adjunct to their present system to supply isolated buildings and residences, which can be reached neither by their present mains nor by electric lights. If they obtain the rights for this gas, they will have a weapon which will be as much stronger than the Welsbach burners, as the acetylene flame is stronger than the Welsbach light. To produce this gas or calcium carbide, the gas companies must put in electric plants, which when not in use making carbide, can be placed in competition in electric lighting.

There are places and many of them where nothing will ever supersede the use of electric lights, but when you consider that only 5 per cent. of the residents of Southern Wisconsin are reached by gas and only 30 per cent. are reached in Milwaukee, and that even less can be supplied with electric light, there is a field opened which is wonderful in the possibilities for successful investments and large business.

Most of your lighting plants are idle during at least half the time, and could thus be made producing plants for the whole time, and you could reach a territory which cannot be reached by either the gas companies or yourselves without large outlays for extensions, and, in most cases, not reached at all.

Of the following facts I am certain: 1. The gas is intensely brilliant. 2. It has a decidedly disagreeable odor if it escapes without being burned, and when burned emits no odor or smoke. 3. The gas can be distributed for much less cost (considering the interest on the investment) in cities, and also to every resident of the State, whether in the city or country. 4. The same amount of light can be produced for much less cost than by ordinary gas or electricity, for one-third cubic foot of acetylene gas burned per hour gives more illumination than a 16-candle power incandescent light, or 5 cubic feet of ordinary gas. Allowing a maximum cost of $50 per ton for carbide, delivered either as a liquid or as carbide—

16 C. P. with acetylene (⅓ cubic feet per hour) costs $.0016
16 C. P. incandescent costs practically.............. .006
16 C. P. ordinary gas at $1.76 per 1,000 cubic feet with 4 feet tip................................ .00704

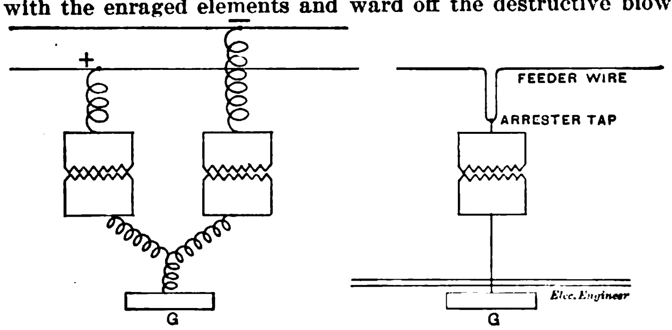
or acetylene costs 16-100 of a cent per hour as compared with electricity at 6-10 of a cent and ordinary gas at 7-10 cent.

The above figures are based on the present method of manufacture and maximum cost, and no allowances are made for the improvements which must necessarily follow experimentation by practical men.

LIGHTNING ARRESTERS.[1]

BY W. R. GARTON.

One of the most trying questions presented to the workers in the electrical industry has been the development of a reliable and accurate lightning arrester, which would effectually cope with the enraged elements and ward off the destructive blow



FIGS. 1 AND 2.

commonly known as the static discharge. To this end many have striven, resulting, not only in numerous developments, but the outcome in many instances has been a most happy solution.

The variety of design is almost as great as there have been ideas to promulgate and carry into effect. But no matter how efficient the device or how perfectly it performs its functions, it is useless unless installed in reasonable numbers, in well chosen places. It is very often considered a trick of the manufacturer in prescribing a goodly number of arresters, but both theory and practice have conclusively proved that during the existence of the static influences, there are established nodal or non-discharging points where a discharge will hardly ever or never occur. These nodal points are constantly shifting, and therefore it is impossible to locate them, and the only possible way of avoiding them is to provide enough places of outlet, that some of them may be at the discharge point.

It is always advisable to place an arrester at the terminal of each line and especially if it is a long one, as it will almost wholly overcome an effect known as the "kick," which is very trying on insulation. When arresters are placed at the ends of lines, it is found that very heavy end or brush discharges take place. The most feasible explanation of the kick which I have been able to formulate is that similar to the jarring of a water pipe after the pressure has been released and suddenly thrown on again by the closing of the faucet. To overcome this concussion a small neck or extension of the pipe is

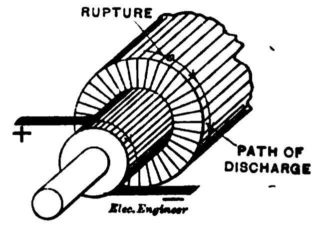


FIG. 3.

made beyond the hydrant. Thus when the strain comes the water is forced to this little end or neck which forms an air cushion and divides the force and neutralizes the shock; the same effect results upon a line, and the end arrester has the effect of overcoming this sudden jar or kick.

The pride of the lineman ofttimes prompts him to inaugurate certain ideas which are most detrimental, such as, for instance, the addition of a few sightly turns or curls in the lead-in or lead-out wires; this alone in many instances is sufficient to completely counteract the good influences exerted by the arrester. I remember having seen this very idea so nicely carried out as to have rendered the lightning arresters of little or no value. (See Fig. 1.) In this particular instance the arresters were in a station connected to an arc circuit. I at once caught sight of these curls of wire leading to and from the arresters. Upon inquiry it was found that they were originally so placed. I also learned that the arresters had always proven very ineffective. I advised their removal and the straightening and shortening of the wires. I learned afterward that this had been done, resulting most satisfactorily. The execution of proper joints or proper contact in the joints is an essential which, quite often, is sadly neglected.

It has always been my custom when puting arresters on a line to insert as much hindrance in the pathway of the discharge, between the apparatus and the arrester, as possible. I almost invariably place the arrester tap in the extreme point of a very abrupt angle or kink in the feeder wire, thus aiding the arrester to turn the lightning to earth. (See Fig. 2). I have found some of these seemingly small things to give admirable results, even though in some instances the so-called arresters were not models.

It is well established that inductive resistance is the most formidable enemy of high frequency currents. Convolutions, turns or curls in a conductor, although few in number, offer more impedance to a discharge than do thousands of feet of straight wire. From this very fact it is obvious how burn-outs in apparatus occur. And it is plain how a small amount of inductive resistance is capable of debarring the static discharge where ohmic resistance cannot withstand. Thus we arrive at the cause for the discharge puncturing the insulation in preference to traversing the path of the normal current.

In the case of the burning out of an armature or field the windings offer a high inductive resistance. The lightning entering at one of the terminals must find a way of escape. (See Fig. 3.) Almost invariably this is through the insulation, or, if an armature, ofttimes from one commutator bar to the next, to an immediate point of outlet. The difference of potential between the point at which the discharge punctures the insulation and the point of leaving the apparatus, due to the resistance of the circuit, which, in the case of an armature, would be counter electromotive force and the field ohmic resistance; would tend to establish an arc maintained by the normal flow. The arc which has followed the lightning over the newly established course, is that which plays havoc. The overcoming of this by the use of a lightning arrester con-

1. Abstract of a Paper read before the Chicago Electrical Association Feb. 7th.

clusively proves that such a device if efficient is invaluable for the preservation and perfect operation of apparatus thus exposed.

The fundamental principle of all lightning arresters is that of discharge points in conjunction with some high resistance between the two sides of the circuit and earth. This is in most instances an air gap. As far as the efficiency of the old original type of air gap, the same as that in use to-day on telephone and telegraph circuits, is concerned, as a lightning arrester, it is most capable. The reason why the simple air gap will not answer, on other than telegraph and telephone circuits is, as has been described, namely, the formation of an arc. The lightning arrester to meet the requirements of railway and electric light circuits must therefore be possessed, not only with the capabilities of an arrester, but also those of a circuit breaker or arc defier.

Lightning arresters are divided into two general classes, viz., those for direct and for alternating currents. Some manufacturers add still another type, that for high tension direct current or arc circuit arrester. The first plan, however, is more predominant. Direct current arresters vary very little from the alternating, in general design, all being constructed upon the same general principles, with perhaps one or two exceptions—such as, for instance, the Wurts types, which vary quite materially in general make-up and form. Those of the Thomson, although of different types, are all constructed upon one fundamental principle, that of the magnetic blow-out.

The direct current arrester is constructed for various voltages ranging from 50 to 5,000 volts, as well as for various current flows, but happily high tension circuits are not circuits of high ampere ranges. The alternating arrester most generally has to do with circuits of small ampere capacity, but high tension, therefore requiring a different mechanism from that of the direct current arrester. But the difference in tension and ampere capacity of the circuit do not always have to do with the different modes of dealing with the two different currents, but the nature of the current to be dealt with more generally controls.

TELEPHONY AND TELEGRAPHY.

FIRE HAZARD FROM TELEPHONE WIRES.

The Boston Manufacturers' Mutual Fire Insurance Company has just issued a number of circulars relating to fire protection, among which we notice the following, covering the hazard from telephone wires:

"Professor Puffer has made special tests with the latest protectors of the American Bell and New England Telephone companies, which are designed to guard against the dangers of crossing of telephone wires by wires carrying currents of great capacities, at pressures varying from 500 to 2,000 volts. In all cases there was a report and a flash of fire when the protector operated. It seemed that if the protector was covered with fine lint, or near a light curtain or the most positions where likely to be used, there would be little or no danger from the flash of the fuse. The protectors are much alike in design, that of the New England Telephone Company being rather the better. Though some improvements are still desired in both protectors, they are in their present shape so good that their immediate use is advised and believed necessary for safety on all telephone wires.

"When we come to the great class of private wires for bells, watch clocks, telephones not the property of the American Bell Telephone Company, but often running out of doors where subject to contacts with high-voltage wires, it is easy to find the greatest risk of fire, because there is usually no attempt to make use of protectors of any kind. There being no demand for such a thing, there seems to be but very little offered by the trade.

"The best remedy is to so run these wires wherever possible that they could not fall on, or be fallen upon, by foreign wires of any kind. It may be noted that any foreign wire may be dangerous, though nominally carrying a harmless current, as it may itself be in contact with a high-voltage wire. When wires cannot be completely isolated, protecting devices equal to those of the telephone companies are necessary for safety, and should be used as soon as something satisfactory can be developed."

SOUTHERN NEW ENGLAND TELEPHONE CO.

The annual meeting of the Southern New England Telephone Company was held at Providence, R. I., on Jan. 28, President M. F. Tyler, presiding. Mr. Tyler in his address said that the reduction made in rates six months ago had borne good fruit in the way of new business, and that the outlook for the future was very bright. He said that reports from all parts of the State showed satisfaction with the service rendered.

The following figures are from the President's statement: Gross earnings, $503,715.55; operating expenses, $348,069.77; net earnings, $155,645.78; fixed charges, $43,742.58; net earnings above all expenses, $111,903.20; paid in dividends, $86,250, or 5¾ per cent.; spent in construction of new plant, $231,000; increase in number of subscribers during year, 1,296, with five new exchanges.

Directors were elected as follows: M. F. Tyler, J. W. Alling, Joseph English, S. E. Herwin, A. H. Robertson and W. E. Downes, of New Haven; A. O. Morgan, of Boston; Thomas Sherwin, of Boston; Lyman B. Jewell, of Hartford.

OBJECTING TO THE NEW CABLE CODE.

At the last meeting of the New York Chamber of Commerce Mr. Thurber reported a preamble and resolution that, whereas the official vocabulary prepared under the direction of the International Telegraphic Conference had been adopted for use in telegraphic messages throughout Europe, from Jan. 1, 1898, and, whereas the vocabulary was inadequate and faulty, it was resolved that the Chamber protested against the use of this vocabulary and directed the Secretary to make known this protest to the cable companies having offices in this city, and desired its members to use their influence to secure the abrogation or revision and extension of the vocabulary. This matter has already been treated fully in the columns of "The Electrical Engineer."

EDUCATIONAL.

INSTITUTE FOR HOME STUDY OF ENGINEERING.

WE have received from the "Scientific Machinist" of Cleveland a copy of the handsome descriptive catalogue of its Institute for the Home Study of Engineering, carried on in that city. The work of the Institute is confined to Electrical and Mechanical Engineering, and this is done very carefully by a system which has proved a great success by the correspondence method. It has not only prepared and printed a comprehensive course specially adapted to this method of instruction, but has designed at great expense an equipment of practical apparatus, which the student can procure at moderate cost, and use at his own home in connection with his study. The staff of the Institute is able to give a course of great merit and commercial value to every one ambitious to learn and to qualify himself for the great work of the present and future. The course is under the direction of Mr. Nelson W. Perry, whose wide engineering training and previous experience in tuition have unusual value for such important work. With him are associated Messrs. N. S. Amstutz and J. C. Lincoln.

The school has also on its staff Arthur R. Curtis, M. E., professor of mechanical drawing in the Colorado State School of Mines; Mr. H. F. Cook, M. E., and others.

The officers of the Scientific Machinist Company are: F. D. Leslie, president; J. H. Norton, treasurer, and G. A. Robertson, secretary. This company publishes the "Scientific Machinist," founded in 1881. Its circular matter is creditable in form and style.

THE ELECTRICAL ENGINEERING COURSE IN THE SCHOOL OF MINES, COLUMBIA COLLEGE.

The 1895-96 programme of the Columbia College course in electrical engineering has been received. The officers of the electrical engineering department are Dr. Francis B. Crocker, Professor, and George Francis Sever, Instructor. Professor Pupin and Mr. Freedman, of the Department of Mechanics, devote nearly all their time to instruction in the theoretical branches of electrical engineering. The regular four-years' course leading to the degree of Electrical Engineer (E. E.) is designed for the education of professional electrical engineers who intend to devote their lives to the practice of this profession, either as teachers in colleges and scientific schools or as engineers, managers, or experts in manufacturing or other industrial enterprises.

The course of instruction includes not only all branches of theoretical and applied electricity, but also the other collateral sciences which have been found by experience to be required by the electrical engineer, such as mathematics, physics, chemistry, drawing, analytical mechanics, mechanical engineering, including a thorough course in steam and other engines, as well as transmission machinery; general engineering, including construction in masonry, iron, steel, and wood, also forms part of the course.

Hence the graduate in the course in electrical engineering is provided not only with a thorough knowledge of the principles and practice of electricity, but also with such a broad and liberal education in the allied sciences as will prepare him for every demand that is likely to be made upon him in after life in connection with his profession, and will also enable him to become an investigator.

The instruction is by lecture, recitation, laboratory and drawing-room practice, with periodical examinations.

Special attention is given to new methods and forms of apparatus in order that the student may be brought fully abreast of the rapid progress of electrical science and practice.

Frequent visits are made to the numerous electrical factories, stations, and other establishments in and about New York.

THE LEHIGH UNIVERSITY, South Bethlehem, Pa., has just issued a pamphlet relating to the work of its School of Mechanical Engineering, which is under the direction of Professor J. F. Klein. The brochure is full of interesting data and is accompanied by a schedule of the mechanical engineering course.

SOCIETY AND CLUB NOTES.

MASSACHUSETTS ELECTRICAL ENGINEERS AND MECHANICS' ASSOCIATION.

The following is a list of the officers of this association for the ensuing year: Past president, Joseph L. Winn, with the Bryant Electric Company, Cambridge; president, John A. Collicott; superintendent inspection department, Messrs. Frank Ridlon & Co.; vice president, Chas. A. Fuller, with the Boston Electric Company; financial secretary, Lewis T. Hoffman, inspector Edison Illuminating Campany; recording secretary, Geo. V. Rowe, Boston Electric Company; treasurer, Chas. H. Toner, electrician Herald building; chaplain, James L. Gethins, with the Boston Fire Alarm Company; conductor, James M. Costello, electrician; assistant conductor, E. B, Fairchilds, electrician; librarian, Chas. Johnson, with Edison Illuminating Company; inside guide, Geo. E. Kerby, electrician; trustees, James E. Cole, chief inspector wires, Boston; E. O. Lundin, superintendent lamp department, Boston Electric Company, and Chas. Clark, electrician.

This association was organized April, 1890, is in a flourishing condition, and has about eighty members. The association meets every 2d and 4th Monday nights at 3 Boylston Place, Landmark Hall. The sixth annual ball of this association was held in Copley Hall on the evening of Feb. 10, and easily excelled all balls of the season in electrical displays. The hall was decorated with bunting, flags and foliage and with electrical displays and designs in incandescent lamps, of which over 1,800 were used.

Mr. John A. Collicott, president, and Mr. James Winn, chairman of the committee on arrangements, did all in their power to surpass all the previous balls. Many prominent electrical men were present.

THE HENRY ELECTRICAL CLUB.

On January 24 Dr. Louis H. Laudy delivered a lecture on "Electric Meters" before the Henry Electrical Club. He introduced the subject by illustrations from the gas meter and pointed out the advantage the electric meter possessed in the ease with which a fraction of the total amount could be measured.

Electric meters might be divided into the following classes: Electrolytic, thermal, differential time meters, motor meters, and photographic, or continuous record meters. The desirable features in a good meter were many, and no one yet introduced could be said to possess them all. Among these features were accuracy, small consumption of energy, simplicity and durability, and constant rate of error under all conditions of temperature.

Dr. Laudy described and showed in operation the leading styles of meters, together with some laboratory instruments which he said were far too delicate and expensive for commercial use. He told of the trying conditions under which meters were often placed, and said that while many had been invented very few had attained commercial success.

At a meeting of the Henry Electrical Club, held on Feb. 7, Mr. Joseph Sachs delivered a lecture on "Electric Heating and Its Applications."

To within a few years ago, the lecturer said, the well-known effect of an electric current heating the conductor through which it passed had not been commercially utilized. Electric heating had been regarded only as an undesirable bye-product.

Now, however, the principle had been applied to a variety of uses, and it was possible to employ electricity in many domestic operations.

Cooking with electrically heated utensils was yet too expensive to be generally adopted, but in many cases it possessed advantages over direct heating.

The heat was applied just where it was required; it was under perfect control, and there was the greatest cleanliness.

But it was in its application to the arts that electric heating had shown its greatest development. In the electric furnace the intense heat of the electric arc was employed with great success in reducing refractory materials, and in the production of chemical compounds. Carborundum and calcium carbide were now produced in large quantities, solely as a result of the introduction of the electric furnace.

In welding, the electric process was superior to direct heating, as it developed heat at the welding points only.

Mr. Sachs made a large number of successful experiments, illustrating every point in his lecture.

MINNEAPOLIS ELECTRO-TECHNIC CLUB.

"The Electro-Technic Club" has been formed in Minneapolis. Its membership will be restricted to electrical engineers, or those engaged in allied work, and its territory will include the whole Northwest. The headquarters of the club are located at Room 23, Syndicate Block. The following are the officers and charter members: President, Charles L. Pillsbury; first vice president, Edward P. Burch; second vice president, Charles H. Chalmers; secretary, W. E. Stephenson; treasurer, George A. Lintner.

Professor George D. Shepardson, Edwin B. Burch, Charles H. Chalmers, George A. Lintner, E. A. Scofield, W. W. Dakin, Frank W. Springer, C. L. Pillsbury, V. I. Gray, W. I. Gray, A. H. Savage, W. E. Stephenson, Frank Reidhead, F. E. Chapman and Harry Lackore constitute the membership.

THE ELECTRIC LIGHT ASSOCIATION OF PENNSYLVANIA.

At the last meeting of the Executive Committee of this association, held in Philadelphia, Mr. John R. Wheeler was elected Secretary to succeed Mr. C. A. Woole, resigned. All communications intended for him should be addressed to 403 Grant street, Pittsburg, Pa.

The Secretary will, before the next annual meeting of the Association, visit the various companies in the state, with the view of effecting a more compact and vigorous organization of the electric light interests, the need of which, it is believed, is apparent to all concerned.

The annual meeting of the association has been postponed to Wednesday, April 1, 1896, at 2 o'clock, p. m., to be held at the Commonwealth Hotel Harrisburg, Pa.

FINANCIAL.

SALE OF THE PHILADELPHIA EDISON CO.

The terms for the purchase of the Philadelphia Edison Company by the Pennsylvania Heat, Light and Power Company were practically agreed upon at a meeting of representatives of the two corporations last week. Several matters still require adjustment, but the understanding is that everything will be settled within a few days or a week. The terms of the Edison Co. were accepted, and the 20,000 shares of stock in that company will be taken at $150 by the Pennsylvania Company.

President Charles M. Swain, of the Edison Company, is quoted as follows: "The negotiations are still pending. The Pennsylvania Heat people accepted our ultimatum of $150 a share for our stock and agreed to pay $50 in cash and $100 in trust certificates, or bonds, secured by a deposit of the stock. There are a great many matters of detail to perfect, and there are still two or three points on which we have been unable to come together. Until those are agreed upon we cannot say that the transaction has been perfected. We will meet again, probably in a few days or a week, but what the result will be I, of course, cannot say."

The consummation of the purchase on the part of the Pennsylvania Heat, Light and Power Company will require the expenditure of an even $1,000,000 for the $50 on the 20,000 shares. For that purpose it will be necessary to call for another assessment on the stock. The first call netted $1,000,000, but, as certain expenditures have been made, there is probably not more than $800,000 in the company's treasury at this time. A call for $5 a share, netting $250,000, would therefore be sufficient, but that would leave no money in the treasury for extending and operating the system. It is probable that, while making the call, it will be made for $10 a share, which would give the company a good working capital of nearly $300,000 after paying for the Edison stock.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED FEB. 11, 1896.

Alarms and Signals:—

ELECTRICAL BURGLAR ALARM. C. Coleman, Chicago, Ill., 554,505. Filed Nov. 20, 1895.

In a burglar alarm, the combination with a signaling device and a meter adapted to control it, of an electrical circuit, including said meter, and extending from the office to the guarded structure, and permutating rheostats arranged in said circuit and located at distant points.

Galvanic Batteries:—

BATTERY. W. S. Doe, Brooklyn, N. Y., 554,247. Filed Sept. 18, 1895.

Consists of a closed vessel forming an extension of the porous cup to form a receiver for the gas emanating from the depolarizing fluid and a reservoir for the latter.

VOLTAIC BATTERY. S. R. V. Robinson, Brooklyn, N. Y., 554,427. Filed May 9, 1894.

Designed for reducing the local action in the battery.

Conductors, Conduits and Insulators:—

ELECTRIC CABLE. T. Guilleaume, Mulheim-on-Rhine, Germany, 554,263. Filed March 19, 1895.

An electric cable comprising a main conductor and a safety conductor, so that upon the safety conductor breaking, the current is diverted from the main conductor, before the latter breaks.

INSULATING JOINT. G. J. Carson, Chicago, Ill., 554,332. Filed Sept. 23, 1895.

Consists in certain peculiarities of the construction.

INSULATING JOINT. L. McCarthy, Boston, Mass., 554,394. Filed Oct. 14, 1895.

Consists in applying a suitable quantity of dry powder insulating substance, at the places where air spaces are likely to be formed in the completed article, and subsequently rendering such substance plastic and solid by the application of heat.

CONDUIT FOR ELECTRIC CONDUCTORS. F. Fuller and J. M. Kinney, Boston, Mass., 554,631. Filed May 24, 1895.

Consists of a sheet of metal bent to form a tube by bringing its longitudinal edges together and having its inner and outer sides treated with an insulating and fireproof substance.

Distribution:—

THREE-WIRE ELECTRIC SYSTEM. E. M. Hewlett and W. B. Potter, Schenectady, N. Y., 554,270. Filed Sept. 10, 1895.

Allows a compound-wound generator to be thrown into either side of a three-wire system.

METHOD OF ELECTRICAL DISTRIBUTION. J. Burke, Schenectady, N. Y., 554,240. Filed Dec. 24, 1894.

A method of supplying from a single generator or group of generators current of different potentials in two or more electric circuits.

REGULATING PHASE RELATION OF ALTERNATING CURRENTS. E. J. Berg, Schenectady, N. Y., 554,230. Filed Oct. 8, 1895.

Regulating the phase relation of alternating currents so as to increase the efficiency of a system of distribution.

METHOD OF TRANSFERRING FEEDERS. J. Burke, Schenectady, N. Y., 554,239. Filed Dec. 24, 1894.

A method whereby feeders or any desired electrical apparatus may be transferred from a circuit of one potential to another.

Dynamos and Motors:—

ELECTRIC MOTORS. J. H. Guest, Boston, Mass., 554,365. Filed Dec. 23, 1893.

The energizing coils for the armature are mounted on the motor frame the same as are the field magnets.

COMMUTATOR BRUSH. O. P. Loomis, Bound Brook, N. J., 554,369. Filed Feb. 13, 1895.

The combination of alternately arranged layers or strips of metal of high conductivity and metal of high resistance, and a fastening device for securing the outer ends of said strips together, said device being insulated from said strips.

ARMATURE FOR INDUCTION MOTORS. A. L. Cushman, Concord, N. H., 554,617. Filed March 30, 1895.

A coil composed of an active high resistance portion and two or more low resistance portions, the high resistance portion and one of the low resistance portions being constantly in series and means for cutting out the high resistance.

CONTROLLER FOR ELECTRIC MOTORS. W. B. Potter, Schenectady, N. Y., 554,307. Filed Aug. 5, 1895.

Its object is to so arrange a controller that it may be adapted to give a greater number of combinations by which the speed of the motors may be regulated.

CONTROLLER FOR DYNAMO ELECTRIC MACHINES. W. H. Knight, Lynn, and J. W. Darley, Jr., Baltimore, Md., 554,276. Filed May 6, 1893.

A device for changing two or more dynamo electric machines, especially motors, from series to parallel connections.

Electric Railways:—

TROLLEY AND SWITCH FOR ELECTRIC RAILWAYS. L. L. Stimpson, Boston, Mass., 554,350. Filed May 2, 1890.

The normal position of the trolley and the point of contact is in a vertical line through the center of the car, held there by a spiral spring in the upper portion of the trolley pole, which lengthens it till the wheels strike the wire, and by a cord or tow line running from the upper end of the trolley pole to the forward end of the car.

ELECTRIC LOCOMOTIVE. C. F. Uebelacker, Cleveland, O., 554,353. Filed Sept. 6, 1893.

Means for supporting the motor and protecting the gearing.

UNDERGROUND CONDUIT FOR ELECTRIC RAILWAYS. W. S. Merkle, St. Louis, Mo., 554,450. Filed March 29, 1894.

Details of construction.

TROLLEY GUARD. J. H. Beazan, Milwaukee, Wis., 554,571. Filed March 19, 1894.

The combination of a trolley arm and its wheel of a pair of upwardly divergent guard arms, an arm upon the rear side of the trolley arm, and suitable connection between said extension and downward extensions upon said guard arms for normally sustaining the latter at substantially right angles to the wire.

Lamps and Appurtenances:—

MEANS FOR SUPPORTING AND MOVING ELECTRIC LAMPS. J. Dempsey, Berlin, Conn., 554,245. Filed April 1, 1895.

ELECTRIC LIGHT CABINET. E. L. Slocum, Pawtucket, R. I., 554,379. Filed March 21, 1895.

A convenient electric light apparatus for making medical examinations.

ELECTRIC LAMP HOLDER FOR BICYCLES. E. D. Rockwell, Bristol, Conn., 554,459. Filed May 10, 1895.

ELECTRIC ARC LAMP. J. A. Seaverns, Boston, Mass., 554,542. Filed March 14, 1895.

The combination with carbon holders and a clock mechanism adjusted for a predetermined rate, a coil to govern the clock mechanism, whereby the arc may be continuously maintained.

Measurement:

ELECTRICAL MEASURING INSTRUMENT. E. Thomson, Swampscott, Mass., 554,321. Filed Nov. 12, 1895.

An electrical measuring instrument in which a stationary electric circuit is so arranged as to cause rotation or a change in position of a movable coil or circuit.

Miscellaneous:—

METHOD OF PRODUCING MOLDS FOR PAPER-MAKING MACHINES. S. Crump, Spokane, Wash., 554,243. Filed May 21, 1895.

Relates to improvements in the manufacture of decorated paper and pulp boards. The matrix is deposited electrolytically.

METHOD OF AND MEANS FOR DETECTING GROUNDS. J. F. Kelly, Pittsfield, Mass., 554,275. Filed June 17, 1895.

Consists of two wings, each having the potential of one of the branches of the circuit, in combination with the needle whose potential is maintained at zero, lying within the influence of said wings.

MACHINE FOR CONNECTING ELECTRIC CONDUCTORS. H. J. Savory, Somerville, Mass., 554,541. Filed April 17, 1893.

A machine for connecting a small electric conductor to a larger one by upsetting one within the other; a hand-set provided with a clamping device rigidly attached to the hand set.

ELECTRIC TYPEWRITING MACHINE. J. L. Garber, Sidney, O., 554,594. Filed Feb. 26, 1892.

ELECTRIC GAS LIGHTER. H. G. Grier, Philadelphia, Pa., 554,622. Filed Nov. 7, 1895.

A jet of the mixed air and gas is projected in proximity to the point at which the spark is formed; adapted to Welsbach burners.

ELECTRIC HEATER OR RHEOSTAT. F. Kraemer and M. Kruger, Chicago, Ill., 554,632. Filed Jan. 7, 1895.

Comprises a prepared carbon resistance-stick hermetically embedded in a plastic body composed of one part of cement, two parts of sand and one part of water.

Switches, Cut-Outs, Etc:—

AUTOMATIC CURRENT REGULATOR. S. C. C. Currie, New York, 554,414. Filed May 23, 1895.

A process and apparatus for the automatic protection of secondary batteries during their charge and discharge so as to prevent their injury by a too rapid condition of change.

AUTOMATIC CUT-OUT FOR ELECTRICAL CONVERTERS. W. J. Greene, Cedar Rapids, Ia., 554,508. Filed Sept. 30, 1895.

A method of automatically cutting in and out electrical converters.

ELECTRIC SWITCH. H. B. Whitehead, Memphis, Tenn., 554,557. Filed Aug. 29, 1894.

A switch capable of being used as an ordinary switch and also as a cut-out for preventing the passage of an excessive current to a particular portion of the circuit.

DISTRIBUTING BOX AND FUSE PLUG. P. S. Brown, Toledo, O., 554,438. Filed April 19, 1895.

Relates to improvements in a "distribution box," and also to an improved fuse plug adapted for use both as an adjunct to said distribution box and independently of the same.

Telegraphs:—

TELEGRAPH RECEIVER. L. E. Oehring, Chicago, Ill., 554,395. Filed July 20, 1893.

The combination with an electromagnet and an armature lever, of a punch positively moved by said armature lever to perforate the tape, and a releasing dog for permitting the return of the punch independently of the movement of the armature lever.

Telephones:—

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 554,399. Filed July 2, 1895.

Permits complete or thorough connections between different lines to be made without leaving any unnecessary instruments or cables appended to the lines.

ARM-REST AND TABLE FOR TELEPHONES. F. Hofmeister, Racine, Wis., 554,488. Filed Aug. 5, 1895.

Comprises a frame, a folding table, an arm-rest, movable in the frame, a bell crank and a rod connecting the bell crank to an arm attached to the table and a spring adapted to fold up the table and elevate the rest.

REPORTS OF COMPANIES.

ANNUAL MEETING OF THE NEW YORK EDISON CO.

At the annual meeting of the Edison Electric Illuminating Co. of New York, held Feb. 11, 60,376 shares of the 79,380 shares, or about 75 per cent., were represented. The following directors were unanimously elected: A. A. H. Boissevain, R. R. Bowker, C. H. Coster, Charles E. Crowell, R. Fulton Cutting, Thomas A. Edison, W. E. Glyn, Arthur Curtiss James, D. O. Mills, Geo. Foster Peabody, W. A. Read, Francis S. Smithers, Spencer Trask. The only change from last year is the election of Mr. R. Fulton Cutting in the place of Mr. Geo. F. Gregory, deceased.

The president's report shows that at the end of 1895 the company had on its books 6,677 customers, and that it operated 271,123 16 c. p. lamps; 12,046 h. p. in motors, and 3,424 arc lights.

MONEY TALKS.

"Inclosed you will find an expression of our appreciation of "The Electrical Engineer." It is a money order for $3 for our 1896 subscription. Money talks."

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

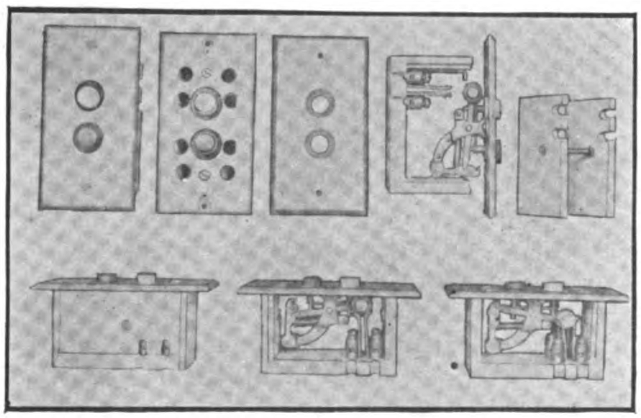
THE SOUTHWARK FOUNDRY AND MACHINE CO.

The catalogue we have received from the Southwark Foundry and Machine Company of Philadelphia is remarkably well done. The binding would not disgrace a library volume, while the type and illustrations are unusually good. Altogether, the get-up of the work is such as to encourage its preservation for permanent reference. Much space is given to a description of the specialty of the company, Porter-Allen engines of various types, while vertical, blowing, reversing and waterworks pumping engines, compressors for natural gas, centrifugal pumps and hydraulic and marine machinery and ordnance are duly treated.

The works of the company are exceptionally well equipped for the turning out of the highest class of foundry and machine work. The machine shops have an aggregate floor space of 65,500 square feet. The main erecting shop, which is 76 feet wide by 253 feet long, is equipped with two electric cranes, each capable of handling fifty tons. The iron and brass foundries, the boiler, pattern and smith shops are also fitted with the most approved modern appliances.

THE PAINTER-MORRISON FLUSH SWITCH.

The Morrison Southern Electric Co. of Baltimore, Md., have placed upon the market a novel push-button flush switch, which possesses several features not shown in any switch heretofore brought to our notice, and is claimed by the inventor, Mr. Geo. E. Painter, to be the only flush switch which combines simplicity of construction with perfection of mechanism. Porcelain being adopted for the base and sides, makes the switch entirely fire and damp proof. They can be easily wired without taking apart. Even after placed in the wall the wires can be easily adjusted by simply removing the face-



The Painter-Morrison Flush Switch.

plate, which is also made in various finishes, to harmonize with the decorations of the room, and need not be put on until all other work is done. They can be placed in groups, being accessible in all their parts, and are so constructed that they are positively non-arcing.

Both black and white buttons are always out, and indicate by the touch whether on or off, and are easily operated. All parts are interchangeable. The make and break arc is quick, and the connection is positive. The switch is 10 ampere, double pole.

MICANITE IN FOREIGN LANDS.

The foreign business of the Mica Insulator Company has grown largely during the last six months, so that they have increased their facilities for manufacturing their well-known insulation, Micanite, the company having made additions to their factory in London. European manufacturers of electrical machinery are using Micanite largely in the construction of their various designs of apparatus, and the company is to be congratulated upon the success which their insulation has met with in foreign countries.

THE JEWELL BELTING COMPANY, of Hartford, Conn., has issued a new pamphlet on their pulley-covering material which they will be glad to supply to any engineers of light or power stations on application. It is worth having.

THE GORDON-BURNHAM PRIMARY BATTERY.

A primary battery, which has attracted wide attention for its extremely successful and varied work where a battery whose action is constant is necessary, is the Gordon battery, which has been on the market for the past year. This battery has made a record for itself among steam railroads, which use electric signals where the very highest grade of battery has to be used to obtain reliable results.

The Gordon battery, an illustration of which we show on this page, is entirely different from any other battery now in use. For the operation of railway signals a successful primary battery must be one of great constancy and absolutely reliable under all conditions of weather. This has been demonstrated to be true of the Gordon cell throughout the United States, some of these cells being in use on every steam railroad in this country. The battery cannot be frozen, and therefore requires no protection from the cold, such as is usually given to the gravity cell in this service.

The construction of the cell and the elements used are entirely new and novel. They are made in two sizes, No. 1 being of the standard size—6x8 inches—and the No. 2 size 4½x6 inches, and they are made either with glass or steel jars. The elements used are a specially prepared copper element, which is the highest known depolarizer, which is contained in a perforated metal cylinder. The zinc element is made from highly amalgamated and chemically pure rolled zinc. The solution is

The Gordon-Burnham Primary Battery.

made from a pure hydrate of soda, manufactured from common salt by an electrolytic process, which eliminates all impurities that would impair the strength of an alkaline solution.

The Gordon cell is equally good for open or closed circuit work and will stand on open circuit for an indefinite period without any deterioration, there being no local action whatever. The cell is especially adapted for all forms of electric transmission of sound. For telephone service a cell is required with little or no polarization, one that is long-lived and requires no attention. The Gordon battery being capable of discharging a constant current, does not polarize, and therefore for telephone service it can be used constantly day and night, if necessary, without any noticeable impairment of the quality of transmission, which would be certainly noticed in all known forms of open circuit batteries. The cell is well adapted for the operation of gas engine igniters, and, we may say, that they are used to-day throughout the country in this service. They are also particularly well adapted for all household service, call bell work, etc.

For fire alarm service the battery has made an excellent record in all the large cities of the country, and is being rapidly introduced into the smaller cities and towns. This battery has been widely indorsed by many of the leading steam railroads and manufacturing electricians throughout the country, and the company are in receipt of a number of letters, which speak of the battery in the very highest terms, and in many instances order duplicate equipments. These letters show conclusively that the battery has more than fulfilled all the claims made for it by the company, and that for the work intended it is undoubtedly one of the very best batteries that has ever been put on the market, and is indeed guaranteed by the manufacturers to do three or four times as much work as any other form of primary battery. They are manufactured and sold by the Gordon Burnham Battery Company, 82 West Broadway, New York.

BRADY'S ARC CUT-OUT BOX.

There is perhaps no better known apparatus than the Brady mast arm, of which Mr. Brady's new catalogue informs us there are no less than 20,000 in use to-day in the United States and Canada, and in Europe and South America. This arm is too well known to require description at this time, but

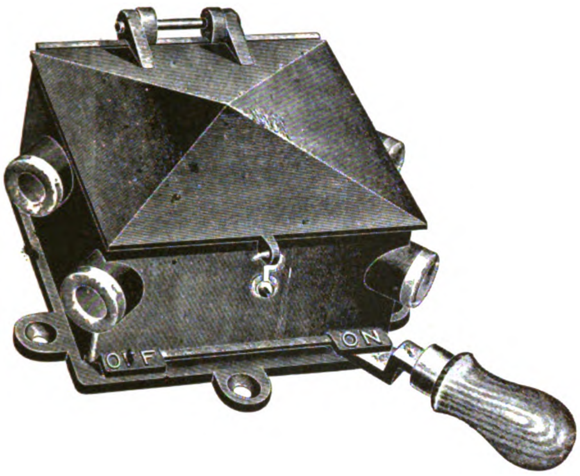


FIG. 1.—BRADY ARC CUT-OUT BOX.

the catalogue contains illustrations of a variety of these arms designed to meet all possible conditions. Thus we find illustrations of the regular side mast arm, in which the lamp is lowered to be trimmed; the improved high pole mast arm, in which the lamp is slid towards the pole and trimmed by the trimmer at the top; and a variety of others.

Among the arc cut-out boxes made by Mr. Brady we note the type shown in the accompanying engraving, Fig. 1, intended for inside use, to be screwed to the wall. When intended for placing on outside exposed places, it is attached

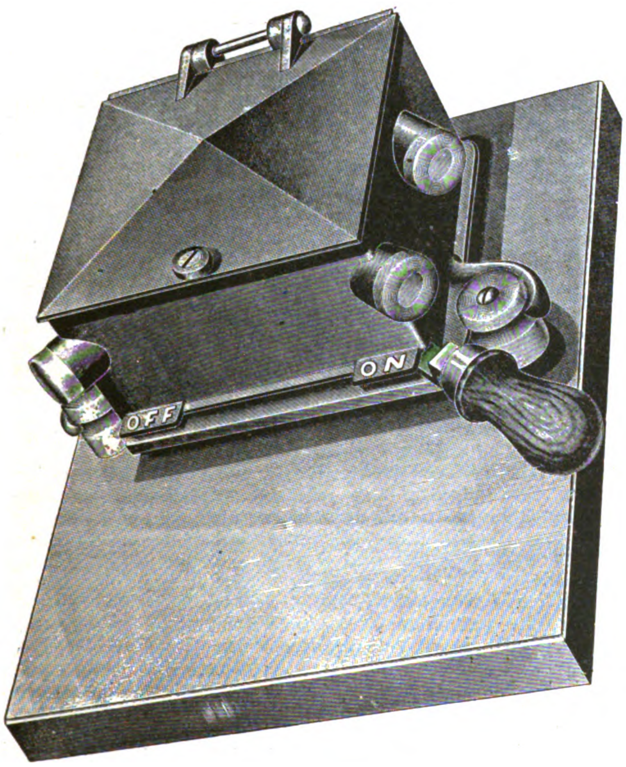

FIG. 2.—BRADY ARC CUT-OUT BOX.

to a pole or building by lugs that fit into the grooves of a No. 5 porcelain knob, thus insulating the box perfectly from the building or pole. See Fig. 2.

Various styles of cut-out hanger boards, thread and house brackets, break arms, lamp hooks, spark arresters, etc., go to make up a most complete line of arc lamp accessories. The Brady factory is situated at New Britain, Conn.

THE CROWN WOVEN WIRE BRUSH.

The advantages of using woven wire brushes are known to almost every one having the care of electrical machinery, but one fault has been their liability to spread at the ends, especially in wide brushes, which causes the brush to cover more segments on the commutator than desired, and this trouble, on some machines, causes sparking and heating.

The Crown Woven Wire Brush Company of Salem, Mass., have overcome this fault in their new brush, the Crown "K," which is illustrated in the accompanying engraving, Fig. 1. This brush is made with a core of very fine braided wires, placed diagonally in the center, with a covering of just as fine cloth, woven like lace, giving more ventilation than in ordinary weaving. It is then sewed with strong thread, which prevents it spreading at the ends.

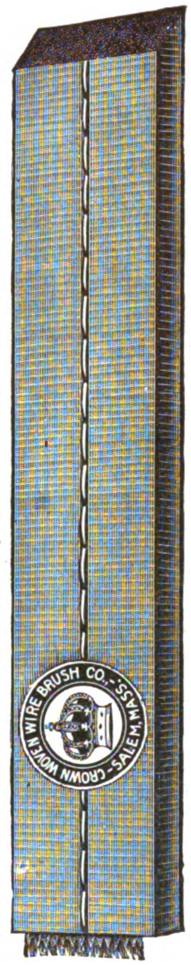

FIG. 1.

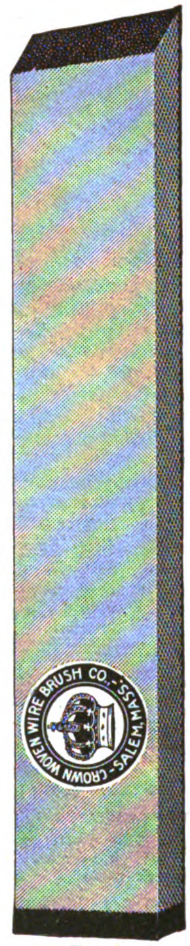

FIG. 2.

This brush differs entirely from other American-made brushes, and is somewhat similar to the imported German brush, and, owing to the duty on the imported, they are sold at a lower price. This company also make the ordinary brush, which we illustrate in Fig. 2, called the "Crown." Their sales are rapidly increasing and their goods are used all over the United States and in many foreign countries.

H. B. Coho & Co. are their New York agents, and carry a large stock of their goods. The Metropolitan Electric Co. have taken the Chicago agency and will shortly carry the largest stock of woven wire brushes in the West.

NEW ENGLAND NOTES.

Boston is to have another electrical supply house, the New England Electric Supply Co. having opened offices at No. 49 Federal street. They have secured a well-lighted and capacious store at this address and will doubtless be heard from more directly and vigorously in the near future.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have just completed for the Silver Springs Dyeing and Bleaching Company, of Providence, R. I., three buildings made with steel frames and corrugated steel coverings, an engine house, a box shop and a boiler-room. The Berlin Company have also lately completed a fire-proof boiler-room for the Passaic Print Works, at Passaic, N. J.

THE RIVAL AUTOMATIC OILING RETURN SYSTEM AND PURIFIER AND STORAGE TANK.

OPERATORS of large steam plants and central station managers know how dividends are made or marred by the observance or omission of economies. The oil bills in the old style central station used to cut a heavy figure in the early days, but the application of the oil filter, together with improved oiling systems, have removed one of the large minor charges from the best equipped modern stations. Among those who have given special attention to oil economy are the Messrs. F. E. Bailey & Co., of Betz Building, Philadelphia, manufacturers of the Rival Oil Purifier. In this apparatus the impurities are removed by subjecting the oil to gentle heat, and no filtering compound or material of any kind is employed. The impurities are deposited at the bottom of the tank and can be drawn off without disturbing the continuity of operating of the apparatus.

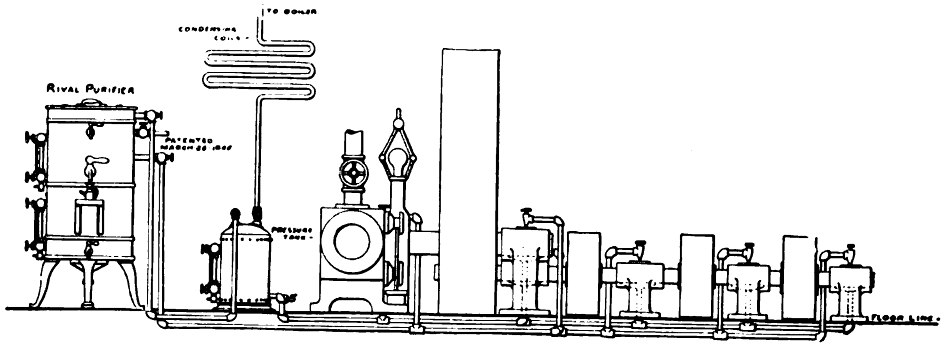

Fig. 1.—Rival Automatic Oil Return System.

The automatic oiling return system used in connection with the "Rival" purifier is shown in Figure 1. As will be seen, a small pipe is connected to each bearing with independent sight feeds from an oil main that is connected to an oil purifier or pressure tank, dispensing with oil cups and their attention, which is very expensive in large plants. The drip from each bearing is conveyed by a small pipe to purifier or to a pressure tank, where it is returned to the purifier, making an entirely automatic and inexpensive system of lubrication and filtration.

NEW YORK NOTES.

THE INTERNATIONAL ELECTRIC CO., 76 Beekman street, makers of Ruhmkorff coils, have felt the demand for induction coils caused by experiments with X-rays. At present they have but one odd-sized coil in stock, while orders on their books are such as will keep them steadily busy for another week or so. The coils present uniformly a handsome appearance.

THE NATIONAL CONDUIT MFG. CO. of New York are issuing an interesting circular to electric light and railway companies, telephone and telegraph companies, and, in fact, to any company which may be contemplating placing their wires underground. The circular is interesting, in the particular that it gives some data on the amount of conduit already laid in many cities by the National company. Philadelphia heads the list with 5,000,000 feet, Boston comes second with 3,000,000 feet, Chicago third with 2,000,000 feet, and New York fourth with 1,900,000 feet. Other cities to the number of about twenty-five are enumerated, which have used amounts varying from 50,000 to 500,000 feet, and a number of other cities, which have used smaller amounts. Many of the most important customers of the National company are also mentioned. The National company keep always in stock about half a million feet of 3-inch conduit, and undertake to start work with 500 men in any city in the country in ten days from receipt of order.

THE MOORE ELECTRICAL CO.

Our issue of Feb. 5, containing the pictures taken by the Moore "etheric" light from vacuum tubes, omitted to give the full list of the officers of the company. These are as follows: E. J. Wessels, president; J. Livingston, vice-president; Leopold Wallach, treasurer; D. McFarlan Moore, electrical engineer and general manager.

ADVERTISERS' HINTS.

THE ELECTRIC APPLIANCE CO. are advertising their "Three Ps," which stand for Packard Lamps, Paranite Wire and Packard Transformers. They claim progress is particularly exemplified in the above-named specialties.

McINTOSH, SEYMOUR & CO., in a list of recent sales, enumerate over 16,000 h. p. of their gridiron valve engines. This style of engine is well adapted to street railway service, and they are installed in some of the largest power houses in the United States. Messrs. J. A. Grant & Co., of Boston, are their New England agents.

THE MICA INSULATOR CO. state that three-quarters of the manufacturers of electrical machinery use "Micanite" as the insulation in the construction of their various designs of apparatus. Micanite and Empire cloth and paper are some of their specialties.

THE GORDON-BURNHAM BATTERY CO. give nine excellent reasons for the complete success of the Gordon battery. Every cell is guaranteed.

THE NATIONAL UNDERGROUND CABLE CO. is now manufacturing the well-known Norwich wires and cables. They will be glad to respond to any requests for information from their headquarters in the Times Building, New York.

THE ELECTRIC STORAGE BATTERY CO.'s "ad." shows an installation in one of the large central stations of this city.

THE WESTON ELECTRICAL INSTRUMENT CO. call attention to their ground detectors and circuit tester. Their portable instruments are recognized the world over as standard. A catalogue describing these and other makes of their reliable instruments may be had upon application.

WESTERN NOTES.

THE LESCHEN-MACOMBER-WHYTE COMPANY have opened offices at 19-21 South Canal street, Chicago, where they will have charge of the business in that territory of A. Leschen & Sons, St. Louis, Mo. They will keep a complete stock of wire rope and cordage blocks, iron, steel, and bare and insulated copper wire and other sundries. F. B. Macomber and George S. Whyte, who are well-known men in this business, will be in charge.

MR. GEO. W. CONOVER, Western Manager of the Perkins Electric Switch Manufacturing Co., Hartford, Conn., recently made a trip in the Northwest, where he did some nice business and reports the future outlook as quite encouraging.

THE INDEPENDENT ELECTRIC CO., Chicago, moved their general office from their factory at Thirty-ninth street and Stewart avenue to 153 Lake street, where they are more easily reached than at their old address. Mr. W. R. Goodman takes care of this end of the business.

THE ELECTRIC APPLIANCE CO. have established quite a reputation for bringing out original advertising novelties. Their latest scheme in this line is certainly a good one, and consists of a complimentary duplicate order book. The book consists of fifty original and duplicate order sheets, bound in a special cover in such a manner that a customer has an impression copy of each written order made at one writing. The books are furnished complete with carbon paper ready for use, and will be sent on application.

EMERSON MOTORS.—The new alternating current power motor of the Emerson Electric Mfg. Co., St. Louis, are rapidly coming to the front as highly successful machines. New orders are coming in daily, and inquiries are received from all over the country. They are particularly adapted for the low alternation systems now being largely introduced, although fully up to the manufacturers' claims on 16,000 alternations, and the above company's guarantee on each machine is sufficient assurance to the most skeptical that a commercially efficient motor for alternating power purposes can now be obtained.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. FEBRUARY 26, 1896. No. 408.

Electric Transportation.

THE WESTINGHOUSE—BALDWIN ELECTRIC LOCOMOTIVE.

As announced in our last issue, the Westinghouse Electric and Manufacturing Company has received the first electric locomotive manufactured under the arrangement entered into some time ago between it and the Baldwin Locomotive Works, of Philadelphia.

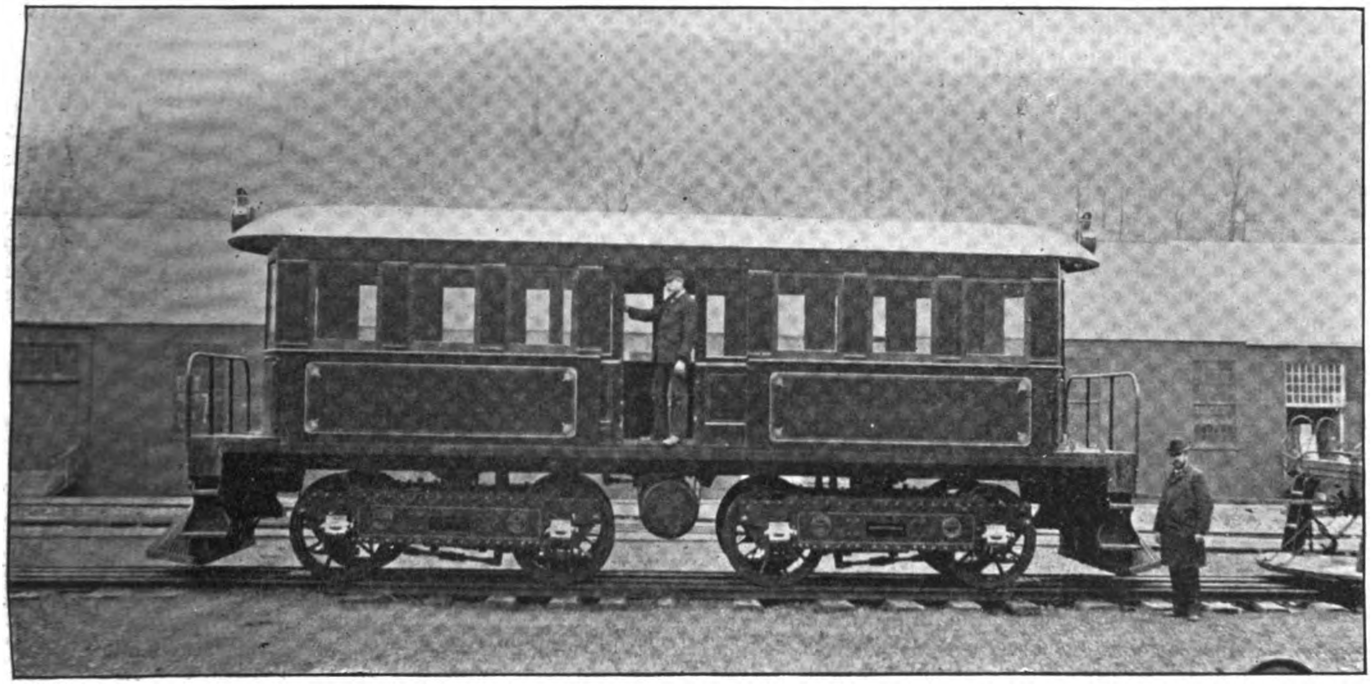
In appearance the locomotive is much different from the steam locomotive, and it also shows radical departures in construction from every electric locomotive hitherto manufactured. It is 38 feet long and 9 feet across. All the operating parts of the locomotive have been placed on the truck and the body of the car will only contain the controlling apparatus, and can be utilized as a receptacle for such appliances as are usually carried by any train. It may also be used as a freight or baggage car.

One of the characteristic features of the locomotive is the truck, which has eight wheels and is constructed in a very substantial manner. The wheels are 42 inches in diameter. There will be four motors of 200 horse-power each, connected to the axles of the locomotive. Thus the entire weight of the locomotive will be placed upon the truck, thereby becoming available for adhesion. This feature of construction will be readily recognized as a very advantageous one over steam locomotives, in which only a fraction of the weight is available for adhesion.

The locomotive completely equipped will weigh 160,000 lbs. The motors are geared, which method has been decided upon so as to enable the company to use more efficient and durable motors and also greatly reduce the cost of the locomotive, which we understand is in the neighborhood of $16,000.

The Baldwin-Westinghouse combination is constructing engines for all kinds of purposes. The one described here is the regular passenger engine, rated at 1,000-horse-power capacity. Then there will be locomotives made to be used in mines. The latter will have six driving wheels and the superstructure will consist of a sheet iron cab. The switching locomotives will also have a cab as a superstructure. There will also be manufactured locomotives for tunnel work, suburban traffic and rack locomotives, as well as for elevated railroads.

It is expected that within a few days the second locomotive, as completed by the Baldwin Company, will be received at the East Pittsburg factory of the Westinghouse Company. This last one will be of the elevated railroad type and is an example of a motor car of the Manhattan Elevated Railroad of New York.



Westinghouse–Baldwin Electric Locomotive for Trunk Line Work.

As far as the speed of these new locomotives is concerned, it may be stated that the motors have been geared to produce a speed of 75 miles an hour, although it may reach 125 miles an hour, if it were demanded. All Westinghouse-Baldwin locomotives will be equipped with air brakes, which will be operated in the usual manner by an air pump, which is underneath the car, and which will be driven by an electric motor.

The Westinghouse-Baldwin locomotives have been designed so as to be utilized with any method of electric traction. They can be used with the trolley system, the third rail system, the Westinghouse electro-magnetic system and they can also be

utilized in connection with the Tesla polyphase system. It is interesting to note that since it became known that the Baldwin-Westinghouse companies are constructing electric locomotives, inquiries have come from all over the world for such machines, indicating the wonderful demand for such locomotives.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—II.

BY

Wm. Baxter Jr.

TESTS of the engine drawing the Empire State Express on the New York Central Railroad have shown results as high as 3⅛ pounds of coal per horse-power hour, but the conditions under which such tests have to be made are such that it is very difficult, if not actually impossible, to obtain exact results. The power developed by locomotives, as shown by the indicator cards, can be considerably out of the way. This fact is recognized by steam engineers, and few, if any, of them would undertake to claim that the results of these tests represent the average working efficiency of locomotives in high-speed service. Even if the indicator diagrams are accurate, which could only be the case if they were taken at a time when the speed was neither decreasing nor accelerating, the results would be better than the average performance, for the very simple reason that whenever tests are made the engineer and fireman do their best to make the coal consumption as low as possible.

It is very doubtful, in my mind, whether the average every-day work of high-speed passenger locomotives can show a result much below four pounds per horse-power per hour. Now the efficiency of such engines is higher than that of engines used for local traffic, because one of the factors upon which the economy of locomotives depends is the high piston speed in consequence of which the loss due to cylinder condensation is greatly reduced; therefore the higher the speed, the higher the efficiency. As freight trains run at a much lower rate of speed than adopted in local passenger service, it follows that the efficiency of freight locomotives must be still lower than that of local passenger engines.

Considering all these facts it would seem reasonable to assume that the coal consumption of locomotives will average in actual service about four pounds per horse-power per hour for express engines; five pounds for local passenger, and six pounds for freight. There is another class of work for which locomotives are used in which the coal consumption per horse-power of useful work performed is very great; just how great it is impossible to say, but in all probability it is in the neighborhood of 20 or 25 pounds per horse-power hour, and in some cases may go even higher. The work referred to is that of drilling engines, used to shift cars and trains around stations and freight yards. The work of these engines cannot be taken into consideration in an estimate of the relative efficiency of locomotives and electric motors, because their wastefulness is due to the fact that while they are burning coal all the time they are only developing power-moving trains for short periods of time at intervals of longer or shorter duration. But the part that these engines play in determining the relative cost of operating a railroad by steam or electricity is important from the fact that the work they do forms quite a large percentage of the total mileage of the road; therefore their bearing upon the subject will be more fully considered later on. What concerns us here is the economy of locomotives in motion as compared with large stationary steam engines.

From the foregoing it will be seen that the great economy in coal consumption claimed for electricity is not fully substantiated by facts. Two pounds per horse-power hour, which was taken as the maximum consumption with large stationary engines, is in reality about the best result that can be counted upon in practice. As to locomotives, six pounds per hour does not represent the average; on the contrary, it may be taken as the maximum consumption, or nearly so. A fair average, taking all things into consideration, would no doubt be about five pounds per hour; therefore, instead of using six pounds of coal in a locomotive to do the same amount of work that a large triple expansion engine will do with about one and a half pounds, it only requires five pounds in the former to do as much work as the latter will do with two pounds. The ratio instead of being 4 to 1, is 5 to 2 in favor of the stationary engine.

But this is the direct ratio between the stationary engine and the locomotive, and as the energy of the former has to be converted and transmitted to the motors on the track, the actual working ratio will drop to about 3 to 2, assuming the efficiency of conversion to be about 60 per cent. It can therefore be said that the actual amount of coal required by electric motors to develop a unit of energy on the track would be about two-thirds of that required by locomotive.

As to cheap and dear coal, it will be found that the difference in cost between the two, to railroad companies, is not very great, especially to those located at a considerable distance from coal mines. The average price of coal at the mines is about 95 cents to $1 per ton. A very cheap grade would probably cost about 25 cents per ton. The cost of coal to railroads not located directly in the coal regions ranges from $1.50 to $3 per ton, the average being about $2.25. The cost of transportation for a cheap grade of coal would be just the same as for the best; therefore the only difference in the actual cost of such coal to the railroad companies would be the difference in first cost at the mines, which would be about 70 or 75 cents per ton. In other words, dear coal would cost on an average about $2.25 per ton and cheap coal about $1.50. As the locomotive consumes three pounds of coal to develop the same amount of energy that the electric motor would develop with two pounds, we have the following as the cash relation between the two systems:

$$\frac{2\times 1.50}{3\times 2.25} = \frac{3.00}{6.75} = 44.4 \text{ per cent.}$$

We thus see that, taking into consideration the difference in coal consumption and also the difference in the price of the two grades used, the cost of a unit of energy developed on the track by electric motors would be about 44½ per cent. of what it is with steam locomotives, so far as the coal bill alone is concerned. As coal, even of the best quality, is a very cheap article, when its cost to most railroads is considered, it follows that a very large consumption would be required to enable the saving that electric motors could make to amount to a sum large enough to justify the abandonment of steam.

The coal consumption of locomotives per train mile varies within wide limits, ranging from about 45 pounds per mile for light passenger service to 100 and more for heavy freight trains; an average of 80 pounds per train mile would certainly not be too high. The cost of this amount of coal at $2.25 per ton would be about 8 cents. As the cost by electric motors would be only 44½ per cent. of this amount, the saving per train mile would be $4\frac{44}{100}$ cents.

The average yearly run of a locomotive is about 30,000 miles; therefore the annual saving in coal per locomotive would be something over $1,300. This saving alone would not be enough to make the adoption of electricity justifiable on roads now in operation; whether it would enable new roads to use the system and compete with steam, would depend upon the relative cost of installation of the two systems.

At a first glance the natural conclusion would be that the electric system would be by far the most costly. That it would cost more, there appears to be no room for doubt, but the dif-

ference would certainly not be as great as a superficial inspection would lead one to believe. Power stations would be required with their expensive machinery. The trolley lines and feeders would also represent a large outlay; but on the other hand, the motors used to haul the trains would cost very much less than locomotives. The repair shops would also be much smaller than those required for a steam equipment, and would be supplied with a smaller amount of machinery and tools for doing repair work. Water tanks and coal sheds along the line of road would not be needed. An electric motor would make more miles per day than a steam locomotive; therefore a smaller number would be required to do the work of the road.

Now when all these various items are added together it will be found that they will go a long way towards offsetting the cost of power stations, trolley lines and feeders. It is therefore probable that a close estimate of the relative cost of equipping a new road with steam or electricity would show that the difference in favor of steam would be only a small percentage, so small, in fact, that the reduced cost of operation, due to the saving in coal alone, would render the electric system more profitable, except in parts of the country where the cost of fuel is considerably below the average price here assumed.

A careful consideration of all the foregoing will lead to the inevitable conclusion that the saving in the coal bill, while sufficient to turn the scales in favor of electricity, when the equipment of new roads is considered, would not justify the replacement of steam on roads already built, except in sections of the country so remote from coal mines that the cost of fuel would be much greater than that upon which these estimates are based.

This at once suggests two phases of the subject. First, we have the question of the advisability of adopting electricity on new roads, and in this direction we find that unless the difference in first cost is much greater than would seem probable, the saving in coal bill alone would render the system the most profitable, even if the cost of coal were less than the average price here taken.

Second, we have to consider the subject in its relation to roads now using steam. Then the question that arises is, Will it pay to throw away the locomotives and install an electric plant? In the case of new roads the saving in fuel bill only has to compensate for the difference between the cost of steam and electric equipment; but with roads already built, this saving must be enough to pay a fair return on the entire cost of the electrical equipment, or else its adoption would not be profitable. But so great a saving would not be probable except on roads located in parts of the country far removed from coal fields, where, on account of the increased cost of transportation, the item of fuel would be a much greater percentage of the total operating expenses than the general average.

In order to be able to form a fair estimate of the bearing that the saving of a portion of the coal bill may have on the total operating expenses of a railroad, it is necessary to know what percentage this item is of the whole expenditure. Fortunately I have before me the reports of several hundred steam railroads and therefore am able to give actual figures as to total operating expenses, fuel, mileage, etc., from which deductions may be drawn. (See Table 1.)

In Table 1, the operating expenses are given in columns 1 and 2, for passenger and freight traffic, respectively. In columns 3 and 4 are given the amounts expended for coal. These figures are only given for the first four roads, because the reports from which this data has been obtained do not give the amounts allotted to each kind of traffic for the other roads. In columns 5, 6 and 7 are given the mileage of passenger, freight and switching trains for all the roads. And in column 8 is given the percentage that the coal bill represents of the total operating expenses in each case.

The percentages in the last column show that the cost of coal becomes a more important factor as the distance of the road from the coal producing centres increases. Thus the percentage on the Pittsburg, Cincinnati, Chicago and St. Louis Railway is only a trifle more than 6, while on the Boston and Albany Railroad it is 11½. The figures do not entirely harmonize. For example, the percentage for the New York, New Haven and Hartford Railroad is 9, which is the same as that of the Pennsylvania Railroad, yet one is some distance removed from the coal supply, while the other passes within a stone's throw of the mouth of the mines. These inconsistencies can be accounted for in a very great measure by the relation between freight and passenger traffic. Those roads on which the mileage of freight trains is high, as compared with the total show a much higher percentage of coal cost to total operating expenses than roads on which it is low. A striking illustration of this fact is the Albany and Susquehanna Railroad, where the coal bill amounts to over 18 per cent. of the total operating expenses. In this case the passenger train mileage is 603,915, while the freight train mileage is 2,027,493. A comparison of the passenger train mileage with the freight train mileage will show at once why the percentage of the coal cost is not proportional to the distance of the road from the coal supply in every case. Thus, the percentage on the New York, New Haven and Hartford and the Pennsylvania roads is the same, whereas it should be much higher on the former. But by looking at the train mileage, we see that while on the latter road the freight mileage is much greater than the passenger, on the former the conditions are reversed. The Albany and Susquehanna Railroad, although not very far from the coal mines, spends for fuel an amount that is more than 18 per cent. of the total operating expenses; but about five-sixths of this amount is allotted to freight service.

The table shows that the coal consumption of freight locomotives is much greater per horse-power than the figures claimed for high-speed passenger engines, and also shows that the opinion that has been generally entertained that electricity would not have much of a chance of competing with steam for freight service, but would have to confine its efforts to passenger traffic, is not well founded; in fact, if it can compete with steam at all it can compete in heavy freight traffic. There are several reasons for this, one of which has already been mentioned, and that is that on account of the slow speed of freight locomotives, the efficiency is much lower than that of passenger engines, especially those used for express service.

TABLE I.—Operating Expenses, Coal Consumption, Mileage and Percentage of Coal Consumption of Total Operating Expenses.

	Operating Expenses.		Coal.		Mileage.			
	1. Passengers.	2. Freight.	3. Passengers.	4. Freight.	5. Passengers.	6. Freight.	7. Switching.	8. Per Cent.
Albany and Susquehanna Railroad	$384,054.38	$1,896.117.84	$67,090.21	$345,970.95	603,915	2,027,493	13,193	18.1

In State of Ohio only.

But in addition to this lower efficiency there is another loss due to the fact that freight trains are very often side-tracked for a considerable length of time and coal is burned without doing work. Then again, at the various points along the line where freight has to be delivered the train has to stop and wait until the cars are disconnected and the train made up again.

TEST OF RAIL BONDS.

WE print below the result of some tests made of various types of rail bonds by Mr. Robert Bunning, Master Mechanic of the Buffalo Railway Company. These tests were made at the power house on Jan. 23, 1896. All of the instruments were of the Weston type, and had just been recalibrated by the Weston Company.

In these tests current was sent through the rails and joints, and its amount and the drop noted. A 9-inch rail weighing 90 pounds to the yard showed a drop of 0.0025 volt per foot, with 250 amperes. A 6¼-inch rail weighing 62½ pounds to the yard showed a drop of 0.005 volt per foot, with a current of 350 amperes. In these tests a milli-voltmeter was used whose entire range was 0.04 volt, so that extreme accuracy was possible:

COPPER BONDS.

Joint of 90 pound girder rail, 6 feet long, with one No. 100 Chicago bond 6 inches long through rail base. Contacts clean, tight and new.

Amperes.	Total drop.	Less drop of rail.	Net drop of bond only.
125	0.04 volt.	0.0075 volt.	0.0375 volt.
1,200	.23 volt.	.072 volt.	.208 volt.
1,400	.35 volt.	.084 volt.	.266 volt.
1,450	.40 volt.	.087 volt.	.313 volt.

Bond very hot at end of tests.

Same joint with same Chicago bond and one No. 80 copper wire, 30 inches long newly fastened with channel pins.

Amperes.	Total drop.	Less drop of rail.	Net drop of bond only.
200	0.04 volt.	0.012 volt.	0.028 volt.
1,200	.28 volt.	.072 volt.	.178 volt.
1,500	.30 volt.	.09 volt.	.21 volt.

esistance of rail .00001 ohm per foot

PLASTIC BONDS.

Joint of 90 pound girder rail, 5 feet long, with standard type of plastic bond between web of rail and angle-plate on one side only.

Amperes.	Total drop.	Less drop of rail.	Net drop of bond only.
160	0.01 volt.	0.003 volt.	.01 volt.
200	.02 volt.	.01 volt.	.01 volt.
950	.08 volt.	.0475 volt.	.0325 volt.
1,200	.095 volt.	.06 volt.	.035 volt.
1,400	.11 volt.	.07 volt.	.04 volt.

Bond cold at end of tests.

PLASTIC PLUG BOND.

Joint of 62½ pound girder rail, 4 feet long, on chairs with Tee rail under joint; one pair of ⅝-inch holes through chair and rail base into top of Tee rail; holes amalgamated and filled with plastic alloy. Resistance of rail, 0.000014 ohm per foot.

Amperes.	Total drop.	Less drop of rail.	Net drop of bond only.
190	0.015 volt.	0.01064 volt.	0.00436 volt.
400	.0425 volt.	.0224 volt.	.020 volt.
1,200	.13 volt.	.0672 volt.	.0628 volt.
1,500	.17 volt.	.084 volt.	.086 volt.

Bond cold at end of tests.

Same joint with one pair of ⅝-inch holes on each side of rail; amalgamated and filled with plastic alloy.

Amperes.	Total drop.	Less drop	Net drop of
190	0.0125 volt.	0.01064 volt.	0.00186 volt.
1,100	.10 volt.	.0616 volt.	.0384 volt.
1,200	.11 volt.	.0672 volt.	.0428 volt.
1,300	.115 volt.	.0728 volt.	.0422 volt.

Bonds cold at end of tests.

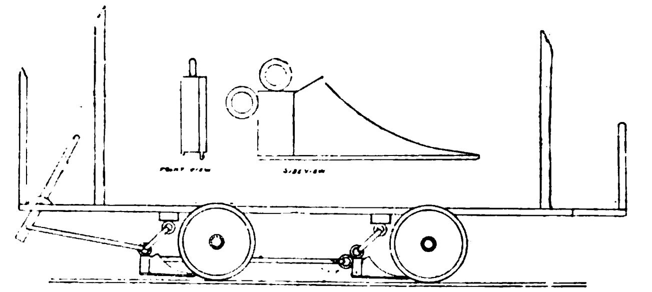
Joint of 62½ pound rail, 3 feet long, with horizontal hole ⅞ inch in diameter in meeting ends of rails, with grooved steel dowel pin, amalgamated and filled with plastic alloy.

Amperes.	Total drop.	Less drop of rail.	Net drop of bond only.
200	0.011 volt.	0.0084 volt.	0.0026 volt.
340	.0225 volt	.0145 volt.	.008 volt.
1,000	.08 volt.	.042 volt.	.038 volt.
1,300	.11 volt.	.0546 volt.	.0554 volt.
1,500	.13 volt.	.063 volt.	.067 volt.

Bond cold at end of tests.

THE PARSHALL EMERGENCY BRAKE.

THE accompanying engravings illustrate an emergency brake adapted for electric street cars, designed by Mr. W. S. Parshall, of Detroit, Mich. As will be seen, the shoes when not in use are suspended from the car by heavy links, and are held from the wheels by the rod connecting with the brake lever. When it becomes necessary to use the brake, the lever is released by the motorman or driver of the car, and the shoes drop in front of and under the wheels, blocking, and



THE PARSHALL EMERGENCY BRAKE.

at the same time raising them clear of the track, thus preventing their becoming flat by grinding on the rails.

The shoes are provided with a bead which runs in the groove of the rail to prevent derailment of thé car. This brake is designed solely to be used in cases of emergency and is not intended to replace the ordinary brake in use at present.

STREET-CAR OPERATION IN CHICAGO.

A fact of large public significance may be gleaned from the mass of dry figures representing the fiscal operations of the three big street railway companies of the city for the year 1895. This fact is that electricity is more than ever the coming propulsive power for surface travel. On the north side, for the first time in the history of the city, perhaps for the first time in any history, electric trolley cars are now being operated more cheaply than cable cars. On the south side the car-mile cost of running cable cars rose from 9.972 cents in 1894 to 10.240 cents in 1895, while the car-mile cost of electric cars fell from 16.904 cents in 1894 to 14.776 cents in 1895. Moreover, the passenger traffic of the south side cable lines showed a decrease of over 1,000,000 passengers as compared with 1894, while the traffic of electric lines showed a large increase. These facts point to one conclusion—namely, the substitution of electricity for the cable. It must be considered, too, that the companies have spent enormous sums on their electric lines. The City Railway Company has spent $2,000,000 in that way, and proposes to spend $2,000,000 more. The West Chicago Company has spent over $2,000,000 and the North Chicago Company a very large sum. The larger the plant the more cheaply in proportion it can be operated. It is not unlikely that the results of the current year will point irresistibly to the discarding of the cable as a means of street-car locomotion.

While street car managements are being carried toward an extension of the application, the public should be moving as unmistakably toward a protection of itself against further encroachment by the trolley system. The public may make up its mind that electric propulsion is coming in more and more. It should also make up its mind that it will not come any further in the shape of the unsightly and dangerous overhead trolley.—Chicago News.

COAL CONSUMPTION ON FRENCH ELECTRIC TRAMWAYS.

Comparative figures of the coal consumed per car-mile run on French tramways, employing different methods of propulsion, are contained in an article on electric lines by E. Cadiat in the "Portefeuille Economique des Machines." As regards storage battery traction on the lines from St. Denis to the Madeleine and from the Opera to Neuilly the car-mileage aggregated, in 1893, 502,060, or 1,376 car-miles per day. The steam engines at St. Denis furnished for this service a total of 6,500 horse-power hours, or 4.72 horse-power hours per car-mile. M. Badois, who reported these figures, gives 2.75 lbs. of coal as the consumption per horse-power hour, and arrives at 12.98 lbs. of coal per car-mile. At Marseilles, during the first two weeks of operation of the trolley system, 150,348 lbs. of coal were consumed to run 19,970 car-miles, and during the second two weeks 150,975 lbs. for 18,983 car-miles. The average is 7.73 lbs., which, however, includes the coal used in connection with the lighting of the cars and the power station.

POWER TRANSMISSION.

HOW TO INSTALL AN ELECTRIC MOTOR FOR BLOWING CHURCH ORGANS.

BY S. H. SHARPSTEIN.

THE manufacturer of electric motors and the people installing them are quite frequently called upon to place small motors for blowing organs in churches, halls, houses, etc. After same consideration and figuring, the electrician or engineer finds that there are some problems about such plants that are not so very easily solved. A person conversant with the business will become thoroughly surprised at times to see what amateurs contrive in the way of belts, shafting, pulleys of all sizes and rheostats in order to try and pump an organ by electric motor.

When the problem of what apparatus to use and what methods to adopt to get the best results for the least money is left for the engineer, if he has got to choose between water from the street mains and a 220 or 500 volt power circuit, usually finds it no easy one to solve. In a case where a very low flat rate can be made for water, the rate to be assured for a number of years, the question is quite easily answered; but when the water has to be paid for by meter such power is very expensive as a rule. The piston water motor, when properly installed works admirably. Year by year sees water motors taken out and electric motors put in, as water companies insist on meters, and as the quality of the water is improved and the supply becomes scarce, as the towns and cities grow, the water rates go up as a rule. When electric power can be gotten by meter at a reasonable price per 1,000 watt hours, water by meter cannot compete. The electric motor being decided upon, then comes the question of efficiency, fire hazard, noise, durability, price and compactness. Everything must be made automatic, so as to need no attention for weeks at a time.

When the engineer considers some of the so-called perfect methods of pumping organs by electricity, and follows the path along which the power has to be transmitted, leading him through mammoth choking coils, shafting, and some belts traveling only 40 or 50 feet per minute at times, and he comes out with a net efficiency of only ½ of 1 per cent., he is filled with wonder at the perfection of the scheme. The matter of methods for a higher efficiency we will consider later.

The question of fire hazard is a vital one, since all about the motor—if placed in the room with the organ and bellows—are materials that will burn readily if once a fire is started; but if properly installed there is no danger from fire with an electric motor, even though it be in the room with the organ. It is quite a common thing to put the motor in a basement and let the pitman that operates the feeder bar extend down through the floor.

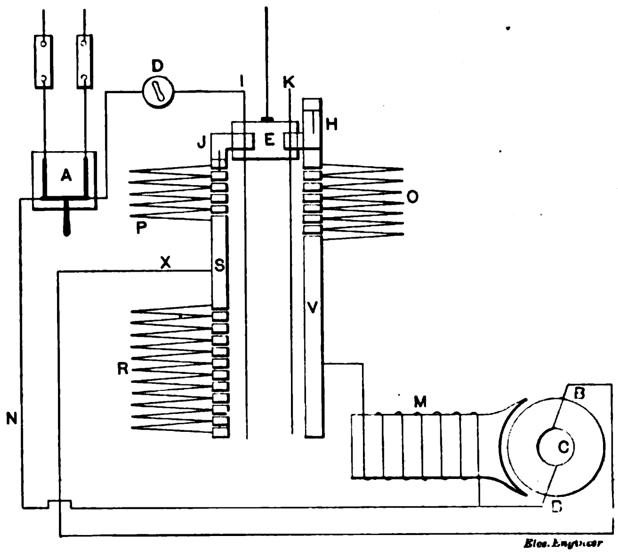
It is surprising to find how a small noise made by a motor will be amplified so as to be heard all over a hall or church. The writer has in mind a motor plant that was placed under a large church to blow a large organ. Four pieces of timber had been framed into the floor timbers directly under the organ, and projected down to a good masonry foundation. Upon these four sticks a good, substantial platform was built, about five feet from the ground, upon which the motor was placed. The motor was about 3-horse-power, and never made more than twelve hundred turns per minute. When started up, the hum of the iron in the armature could be heard all over the church. The armature was toothed, or iron-clad.

Although the commutator was very smooth, it was thought at first that the hum came from the brushes, but on changing to light copper brushes there was no difference that we could perceive. The organ-builder then placed a piece of rubber packing, about one-fourth of an inch thick, under the motor. Still there was most of the noise. There was a perceptible noise from the pitman, shafting and belts, that could be heard in the audience-room of the church and could not be heard in the basement. The audience-room floor was a mammoth sounding board, which carried the vibrations to every pew and up them to every portion of the room. It was thoroughly demonstrated then that all the trappings connected with the pumping machinery should be placed upon something independent of the audience-room floor.

A very short time after placing the motor mentioned above, the writer placed another in a pipe organ just back of the front pipes. The front of the organ was in a hall that was very high; the back of the organ was against a portion of the building that had two floors to the hall's one. Almost all of the organ was placed in the second story, which came part way up the length of the large pipes in the front of the organ. The motor stood on this second floor, about six feet back of the front pipes. This floor upon which the motor stood made a good sounding board, and the least noise could be heard in the hall. The commutator of the motor was greased, so that the brushes did not make any noise. The armature did not hum but a very little, as the machine was small; but a very little irregularity of the belt could be heard as it would strike the pulleys. It was necessary to take the motor out of the organ and place it in a back room; even now the least noise that the pitman may make can be heard very distinctly in the hall.

The question of durability is of vital importance. When once turned over to the purchasers the motor is not apt to get much care, unless some good organ-builder has charge of the organ. The bearings of the motor ought to be self-oiling, and the oil reservoirs ought to be large, so as to hold quite a quantity of oil. The brushes should be carbon, so as not to cut the commutator when not oiled or lubricated otherwise.

One source of great depreciation with some equipments for pumping organs has been the metal points, over which the contact piece keeps moving as the resistance in the rheostat is cut in and out by the bellows working up and down. At first thought it is realized that the speed at which the motor is to work at any one time is determined by the amount of wind the organ is using. When using the wind faster than the feeders are supplying it, the bellows will drop down, and this



METHOD OF CONTROLLING ORGAN BLOWING MOTORS.

lowering, together with the rising of the bellows, enables the engineer to get a point to start from in the regulation of the motor. The method of regulation that has been so much used has been a weight lying on top of the organ bellows. To this weight a string is attached running to a lever or directly to the arm on the resistance box. As the bellows lower, when a sudden demand is made for wind, the weight goes down with the bellows and pulls the lever on the resistance box in such a way as to cut resistance out of the armature circuit, which will have a tendency to make the motor run faster, and hence work the feeders faster to keep up with the demands of the performer at the keys. When less wind is used or the feeders commence sending too much wind into the bellows, the bellows rise up and by means of the string, lever, etc., cut the resistance in and slow up the motor. At the time the bellows get full, there is so much resistance in circuit with the armature that the motor stops, or very nearly so, depending on what is being done at the keys, or whether the organ is leaky or not, which would determine the bellows staying full for any length of time.

To the beginner this method seems all that could be desired, so he sets to work and makes a box with ample resistance in it to choke down the motor and puts about ten points on the face of the rheostat for movable contacts to pass over and puts the same close to the organ and gets it connected up. After some adjusting of lever and weight (right here we might say that a weight is used instead of putting a screw eye in the bellows to prevent pulling anything to pieces in case some lever or string might get fast and not want to move as the bellows go down, and many times it is not necessary to have the weight travel as far as the bellows) the thing is got working in pretty fair shape and all seems to be going on nicely; but the electrician in charge notices a small spark as the movable contact passes up and down over the fixed points.

Next day he comes to see how the thing is working and un-

derstands that the motor is doing all right and the equipment has had a good test since the builders have been very busy tuning ever since the thing was started. This sounds like good news, but as the electrician gets around and looks at the controller or resistance box, there seems to come a sort of serious look over his face. Even when there is nobody at the keys the bellows keep moving up and down some, and this moving of the bellows keeps the contact points on the rheostats sawing. As the movable piece leaves the stationary points the thing sparks four times as much as it did the day before. This is serious, the spark becoming so large that the people about the organ notice it and seem to be fearful that it will set something on fire.

After trying one thing and another, out comes the box, and about 70 or 80 stationary points go in the switch, and this makes the difference of potential so small between the bars that the sparking is stopped and all seems to go on well. The builders get the instrument tuned and then come the efforts of organists to empty the bellows with full organ; but the man who installed the motor is not afraid of that, since the motor is amply large and can do the work without any trouble. But the right man happens to get down at the organ and he plays along with most of the stops in for a time and uses so small an amount of wind that the motor and shafting is almost stopped. All at once he pulls out more stops and seems to make an effort to get down all the keys on the board; the music would have been grand, but before motor and gearing together with the feeders get started the bellows are empty and one great funny noise is made by the organ that tells the story of an empty bellows and some hustling feeders. The bellows had gone away down, the resistance was cut away out, and about the time that the bellows get empty the motor starts out on the emergency trot and the feeders punch the wind into the bellows so fast that the top of the bellows reminds one of the surface of the sea.

This thing is quite apt to occur, especially if the bellows are a little small for the organ and will not hold wind enough to supply the full organ for a short time. This method of regulation is not what it ought to be, for several reasons. Some one will say that he obviated the trouble just mentioned by having the resistance cut out very rapidly as the bellows start down, but if the rheostat is manipulated by hand and all cut out at once it takes little time to get things started if lots of shafting and pulleys are used, and by the time things are under way the bellows are empty.

Compactness is the last point we consider, but is by no means one that wants little attention. Architects seem to think that an organ can be squeezed into almost any kind of a corner, and as a rule the electric motor and its accessories have got to be put in a very small place.

We often see a motor installed to drive an organ when the motor is belted to a counter-shaft with one very large pulley and another one very small in diameter. From the pulley motor the belt runs onto the large pulley and this first belt has a proper speed. From the small pulley on the counter the second belt runs onto a pulley on the shaft that contains the crank that works the pitman. Since the speed of the pitman shaft is so slow, sometimes not over twenty turns per minute, it stands to reason that this second belt must have a very slow speed, even though there is a large pulley on the pitman shaft to have it run over. This arrangement is very cumbersome; it takes up much room and is bad in many respects, although so often used.

The writer has found the following arrangement compact and durable: On the shaft of the motor in place of a pulley put a worm to work into a gear, the worm and gear proportioned properly so that the shaft with the gear will make the proper number of revolutions for the crank and pitman. The inverted hangers to be used for supporting the crank shaft would be best if self-oiling, although the speed is so slow that very little lubricant is necessary if the bearings are large enough and made of good babbitt. The hangers will straddle the pulley end of the motor and if the motor and hangers are placed on a slate slab about two inches thick the whole arrangement is compact and complete. If the motor is to be placed where there must be the minimum of noise the worm and gear will probably have to be cased; but if not there is no reason why it will not run very nicely open or uncased.

An oil cup can be arranged so that when the motor is working, a lever worked by the magnetism of the fields will turn the oil on when the motor starts so as to keep the gear oiled. If the equipment is to get but very little care a small pan under the worm will hold oil and lubricate the thing very nicely. There should be a drip pan under the worm and gear anyhow, even if a cup is used. It is the work of a mechanic to get motor and bearings so arranged on the slab of slate that the whole thing will be stiff and work without noise. When compared with some of the old methods it will surprise a person to see how little space the whole thing, ready for the pitman, will take.

The question of end thrust will come up at once and seem to some to be quite a serious question, too; but if the end of the motor bearing next to the worm is well finished, a vulcanized fiber washer put between worm and bearing, and the worm left on a feather so as to move lengthwise on the shaft, the arrangement will be found to work nicely if the motor bearing is stiff as it should be on the pulley end. Persons not conversant with this work must bear in mind that the whole thing must be made solid and securely fastened to the floor or something similar, or it will hammer and chuck as the crank gets its up and down thrust.

The electrical part of the plant we will try to explain by the use of the accompanying diagram of circuits.

A is a double pole knife switch that should be in a convenient place and opened every time the organ is done with. This cuts the current off from the apparatus in all respects, which is demanded by the fire underwriters, and makes it very convenient when working around the motor.

From the right side of the switch one leg of the circuit leaves, and at D we will consider that we have placed a snap switch of either 500 or 220 volts, as the case may require. This switch must be on the front of the organ where the organist can reach it with ease and should be placed on a piece of slate to make it secure against fire. From this switch the circuit is run up and connected to brass bar I. On the two brass bars, I and K, runs a moderately heavy weight; cheap babbitt makes a good one. Onto this weight are fastened two brushes that travel on the compact columns, S and V.

When the organist is down at the organ and the switch, A, is closed by turning the switch, D, current passes into the metal weight, E, and from there into brush, H, thence down the segment bar, V, through the resistance, O, into the field of the motor, M, and back to the switch. This excites the fields of the motor ready for a start; at the same time the current passes into the other brush, F, through the resistance, P, and thence through wire, X, around through the armature and back to the main switch, A, through the wire, N. The resistance, P, acts as a starting box for the motor and as soon as the brush, F, passes down over the blocks, starts the motor nice and easy, and as soon as the brush, F, gets over this first lot of points the motor and organ feeders ought to have a speed that will furnish more wind than the organ can ever use, allowing quite a margin for leaks in the organ, which are sure to come sooner or later.

The organ builder is supposed to be able to tell the number of times per minute the feeders have got to be emptied to supply the organ with wind, but their estimates do not always hit the mark. The travel of the feeders, their size in square inches, together with the pressure per square inch inside the bellows will give the data that a person has got to work from to determine the amount of work to be done. Sometimes the feeders are wedge-shaped and work like a cover on a book; this adds to the complication of the matter, but with the help of a good organ builder a person can soon estimate the work to be done at the pitman.

To get back to our motor. The weight on the organ bellows attached to regulation wire or cord ought to be so arranged that soon after the brush, F, gets the resistance, P, cut out, the bellows should be three-fourths full, or this should take place before the brush, H, commences to cut out the resistance O. The resistance, O, ought to regulate the motor for all the ordinary work of the organ. This resistance changes the current flowing through the fields and makes the regulation very decided. If the motor is a two-horse-power machine it will always do two-horse-power work while being regulated through this resistance and will respond very quickly as the resistance is cut in or out.

People who have always worked with a resistance in the armature circuit for regulation will be surprised to see how quickly this arrangement will respond to any change in position of bellows so much different from the sluggish action of the motor with resistance in the armature circuit. And again, the amount of current passing through the field wires should be very small, hence high efficiency and no cutting from spark with a few points in the rheostat.

With the controlling resistance in the armature circuit more than double the energy is lost at times in the rheostat than is used in the motor. Some one who has been trying to build a slow speed, high efficiency motor by putting almost all the wire of the whole machine on the armature may say that the arrangement will not work, but a trial will tell the story. The people above mentioned will say that the motor will spark excessively with a weak field, but such is not necessarily the case. If the quantity of iron and wire are kept down in the armature and the fields properly wound the arrangement works very nicely. The motor has got to be quite slow speed

for a small one, but this can be arranged for by using a larger frame than is customary for the size of motor wanted. The resistance, R, will come in use when the organist has stopped playing for a short time, for tuning, etc., if the organ is in good condition and does not leak much. Switch F, cuts this resistance into the circuit with the armature when the bellows get full to the extreme capacity; it ought to stop the motor still if necessary.

It is very convenient to have the starting coils in the iron box with the other coils, but the organist must understand never to commence to play a piece of music that will take much wind until the bellows get time to fill. With the average organ all the resistance wire except the starting coils can be very fine. Since so little current is manipulated in controlling the arrangement there is not much heat to be gotten rid of, hence all can be placed in a small iron box properly ventilated and an iron cover put on. This should suit the most exacting of the examiners for the board of fire underwriters. A piece of slate should be placed between the controlling box and the floor, or any support that the box may be fastened to.

THE SUSQUEHANNA POWER PLANT.

Plans for the construction of the great electric plant, by which the Susquehanna River will be used to furnish electrical power to towns in Maryland and along the Susquehanna in Pennsylvania, and also points in Delaware, have been completed by Clemens Herschel, of New York, the hydraulic engineer, who had charge of the hydraulic construction of the Niagara plant. Work will be begun in the early spring, and in less than a year's time the company expects to be able to furnish power as far north as Wilmington, Del., and as far south as Baltimore. At two falls it is proposed to develop 40,000 horse-power each, and the minimum flow of the Susquehanna River, which is only about 2 per cent. of the time, produces 25,000 horse-power at each fall. The company has acquired most of the land fronting on the Susquehanna River between Conowingo, Md., and the Pennsylvania state line. A great dam and a system of canals will be constructed, in which will be placed the penstocks and turbine wheels for generating the electricity, the whole plan being similar to the Niagara Falls system. Outside of Niagara, the Susquehanna River is the largest Eastern water power near a large city.

POWER TRANSMISSION PLANT FOR COLUMBIA, S. C.

The contract for the construction of the Granby Power House has been awarded to Messrs. W. A. Chapman & Co., the firm which built the Columbia Mills. The power house will be built between the Congaree River Bridge and the power house which is used to furnish electric power for the Columbia Mills. The building will be 184 feet long by 65 feet deep and will have a stone foundation.

Ten thousand horse-power will be generated from the building which will be sufficient to run twenty cotton factories of the ordinary size. To get some idea of the amount necessary to run a mill, the Columbia Mills may be taken as an example where 1,500 horse-power is now used, but in June this will be doubled. Five hundred horse-power will run a mill with 80,000 spindles.

Enough power power can be generated to run all the mills that can be built on the canal, besides being sufficient to light the entire city and furnish motive power for the electric cars.

WOODEN POLES FOR THE NIAGARA BUFFALO TRANSMISSION.

The contract for furnishing 2,000 wooden poles for the power transmission line to Buffalo has been let by the Cataract Construction Company to Thomas Barnard, of Lockport. Mr. Barnard is connected with the construction department of the Western Union Telegraph Company, and has an office in Buffalo.

LIGHT FROM ARTESIAN WELL POWER.

The large artesian well recently sunk at Chamberlain, S. D., is now at work running the electric light and power plant in that town. The water is utilized through a three-inch nozzle, playing upon a Pelton water wheel. The present plant supplies 275 32-candle-power incandescent lamps, but there is sufficient reserve power to run double this number.

CROSSING LIGHTS AT SHERMAN, TEXAS.—The Department of Public Works has been instructed by the Board of Aldermen to cause the railroads to erect and maintain electric street lamps at several street crossings, said lamps to not be of less than 2,000 candle-power each.

ELECTRIC LIGHTING.

ON RADIANT MATTER.—II.

BY WILLIAM CROOKES, F.R.S.

The spectrum of the red light emitted by these varieties of alumina is the same as described by Becquerel twenty years ago. There is one intense red line, a little below the fixed line B in the spectrum, having a wave-length of about 6,895. There is a continuous spectrum beginning at about B, and a few fainter lines beyond it, but they are so faint in comparison with this red line that they may be neglected. This line is easily seen by examining with a small pocket spectroscope the light reflected from a good ruby.

There is one particular degree of exhaustion more favorable that any other for the development of the properties of radiant matter which are now under examination. Roughly speaking, it may be put at the millionth of an atmosphere.[4] At this degree of exhaustion the phosphorescence is very strong, and after that it begins to diminish until the spark refuses to pass.[5]

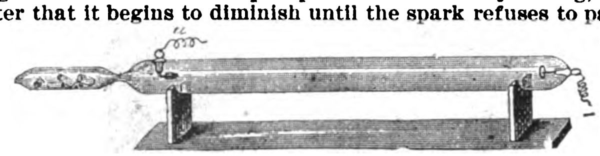


FIG. 5.

I have here a tube (Fig. 5) which will serve to illustrate the dependence of the phosphorescence of the glass on the degree of exhaustion. The two poles are at a and b, and at the end c is a small supplementary tube, connected with the other by a narrow aperture, and containing solid caustic potash. The tube has been exhausted to a very high point, and the potash heated so as to drive off moisture and injure the vacuum. Exhaustion has then been recommenced, and the alternate heating and exhaustion repeated until the tube has been brought to the state in which it now appears before you. When the induction spark is first turned on nothing is visible—the vacuum is so high that the tube is non-conducting. I now warm the potash slightly and liberate a trace of aqueous vapor. Instantly conduction commences, and the green phosphorescence flashes out along the length of the tube. I continue the heat, so as to drive off more gas from the potash. The green gets fainter, and now a wave of cloudy luminosity sweeps over the tube, and stratifications appear, which rapidly get narrower, until the spark passes along the tube in the form of a narrow purple line. I take the lamp away, and allow the potash to cool; as it cools, the aqueous vapor, which

[4]1.0 millionth of an atmosphere equals 0.00076 mm.; 1315.789 millionths of an atmosphere equal 1.0 mm.; 1,000,000 millionths of an atmosphere equal 760.0 mm.; 1,000,000 millionths of an atmosphere equal 1 atmosphere.

[5]Nearly a hundred years ago, Mr. William Morgan communicated to the Royal Society a paper entitled "Electrical Experiments made to ascertain the Non-conducting Power of a Perfect Vacuum," etc. The following extracts from this paper, which was published in the "Philosophical Transactions" for 1785 (vol. lxxv., p. 272), will be read with interest:

A mercurial gage about fifteen inches long, carefully and accurately boiled till every particle of air was expelled from the inside, was coated with tin-foil five inches down from its sealed end, and being inverted into mercury through a perforation in the brass cap which covered the mouth of the cistern, the whole was cemented together, and the air was exhausted from the inside of the cistern, through a valve in the brass cap, which, producing a perfect vacuum in the gage, formed an instrument peculiarly well adapted for experiments of this kind. Things being thus adjusted (a small wire having been previously fixed on the inside of the cistern to form a communication between the brass cap and the mercury, into which the gage was inverted), the coated end was applied to the conductor of an electrical machine, and, notwithstanding every effort, neither the smallest ray of light nor the slightest charge could ever be procured in this exhausted gage.

If the mercury in the gage be imperfectly boiled, the experiment will not succeed; but the color of the electric light, which in air rarefied by an exhauster is always violet or purple, appears in this case of a beautiful green, and, what is very curious, the degree of the air's rarefaction may be nearly determined by this means; for I have known instances, during the course of these experiments, where a small particle of air having found its way into the tube, the electric light became visible, and as usual of a green color; but the charge being often repeated, the gage has at length cracked as its sealed end, and in consequence the external air, by being admitted into the inside, has gradually produced a change in the electric light from green to blue, from blue to indigo, and so on to violet and purple till the medium has at length become so dense as no longer to be a conductor of electricity. I think there can be little doubt, from the above experiments, of the non-conducting power of a perfect vacuum.

This seems to prove that there is a limit even in the rarefaction of air, which sets bounds to its conducting power; or, in other words, that the particles of air may be so far separated from each other as no longer to be able to transmit the electric fluid; that if they are brought within a certain distance of each other, their conducting power begins, and continually increases till their approach also arrives at its limit.

the heat had driven off, is reabsorbed. The purple line broadens out, and breaks up into fine stratifications; these get wider, and travel toward the potash tube. Now a wave of green light appears on the glass at the other end, sweeping on and driving the last pale stratification into the potash; and now the tube glows over its whole length with the green phosphorescence. I might keep it before you, and show the green growing fainter and the vacuum becoming non-conducting;

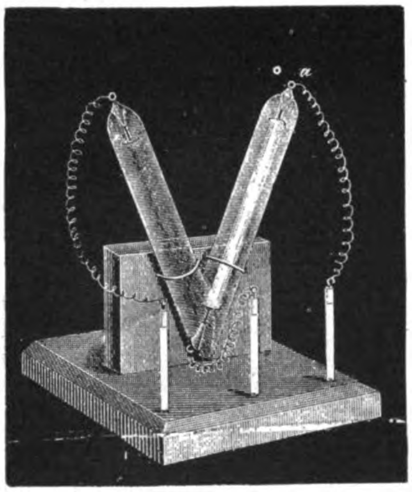

FIG. 6.

but I should detain you too long, as time is required for the absorption of the last traces of vapor by the potash, and I must pass on to the next subject.

RADIANT MATTER PROCEEDS IN STRAIGHT LINES.—The radiant matter whose impact on the glass causes an evolution of light, absolutely refuses to turn a corner. Here is a V-shaped tube (Fig. 6), a pole being at each extremity. The pole at the right side (a) being negative, you see that the whole of the right arm is flooded with green light, but at the bottom it stops sharply and will not turn the corner to get into the left side. When I reverse the current and make the left pole negative, the green changes to the left side, always following the negative pole and leaving the positive side with scarcely any luminosity.

In the ordinary phenomena exhibited by vacuum tubes—phenomena with which we are all familiar—it is customary, in order to bring out the striking contrasts of color, to bend the tubes into very elaborate designs. The luminosity caused by the phosphorescence of the residual gas follows all the convolutions into which skillful glass-blowers can manage to twist the glass. The negative pole being at one end and the

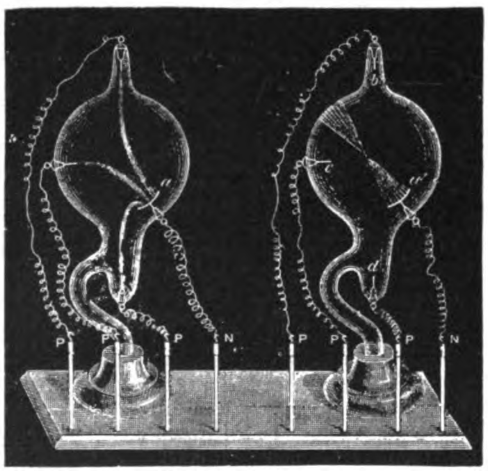

FIG. 7.

positive pole at the other, the luminous phenomena seem to depend more on the positive than on the negative at the ordinary exhaustion hitherto used to get the best phenomena of vacuum-tubes. But at a very high exhaustion the phenomena noticed in ordinary vacuum tubes when the induction-spark passes through them—an appearance of cloudy luminosity and of stratifications—disappear entirely. No cloud or fog whatever is seen in the body of the tube, and with such a vacuum as I am working with in these experiments, the only light observed is that from the phosphorescent surface of the glass. I have here two bulbs (Fig. 7), alike in shape and position of poles, the only difference being that one is at an exhaustion equal to a few millimetres of mercury—such a moderate exhaustion as will give the ordinary luminous phenomena—while the other is exhausted to about the millionth of an atmosphere. I will first connect the moderately exhausted bulb (A) with the induction-coil, and retaining the pole at one side (a) always negative, I will put the positive wire successively to the other poles with which the bulb is furnished. You see that as I change the position of the positive pole, the line of violet light joining the two poles changes, the electric current always choosing the shortest path between the two poles, and moving about the bulb as I alter the position of the wires.

This, then, is the kind of phenomenon we get in ordinary exhaustions. I will now try the same experiment with a bulb (B) that is very highly exhausted, and, as before, will make the side pole (a') the negative, the top pole (b) being positive. Notice how widely different is the appearance from that shown by the last bulb. The negative pole is in the form of a shallow cup. The molecular rays from the cup cross in the center of the bulb, and thence diverging fall on the opposite side and produce a circular patch of green, phosphorescent light. As I turn the bulb round you will all be able to see the green patch on the glass. Now, observe, I remove the positive wire from the top, and connect it with the side pole (c). The green patch from the divergent negative focus is there still. I now make the lowest pole (d) positive, and the green patch remains where it was at first, unchanged in position or intensity.

We have here another property of radiant matter. In the low vacuum the position of the positive pole is of every importance, while in a high vacuum the position of the positive

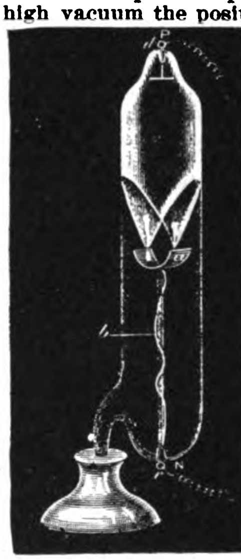

FIG. 8.

pole scarcely matters at all; the phenomena seem to depend entirely on the negative pole. If the negative pole points in the direction of the positive, all very well, but if the negative pole is entirely in the opposite direction it is of little consequence; the radiant matter darts all the same in a straight line from the negative.

If, instead of a flat disk, a hemi-cylinder is used for the negative pole, the matter still radiates normal to its surface. The tube before you (Fig. 8) illustrates this property. It contains, as a negative pole, a hemi-cylinder (a) of polished aluminum. This is connected with a fine copper wire (b), ending at the platinum terminal (c). At the upper end of the tube is another terminal (d). The induction-coil is connected so that the hemi-cylinder is negative and the upper pole positive, and when exhausted to a sufficient extent the projection of the molecular rays to a focus is very beautifully shown. The rays of matter being driven from the hemi-cylinder in a direction normal to its surface, come to a focus and then diverge, tracing their path in brilliant green phosphorescence on the surface of the glass.

Instead of receiving the molecular rays on the glass, I will show you another tube in which the focus falls on a phosphorescent screen. See how brilliantly the lines of discharge shine out, and how intensely the focal point is illuminated, lighting up the table.

NEW EXPERIMENTS ON THE CATHODE RAYS.[1]

TWO hypotheses have been propounded to explain the properties of the cathode rays.

Some physicists think with Goldstein, Hertz and Lenard, that this phenomenon is like light, due to vibrations of the ether,[2] or even that it is light of short wave-length. It is easily understood that such rays may have a rectilinear path, excite phosphorescence, and affect photographic plates.

Others think, with Crookes and J. J. Thomson, that these rays are formed by matter which is negatively charged and moving with great velocity, and on this hypothesis their mechanical properties, as well as the manner in which they become curved in a magnetic field, are readily explicable.

This latter hypothesis has suggested to me some experiments which I will now briefly describe, without for the moment pausing to inquire whether the hypothesis suffices to explain all the facts at present known, and whether it is the only hypothesis that can do so. Its adherents suppose that the cathode rays are negatively charged; so far as I know, this electrification has not been established, and I first attempted to determine whether it exists or not.

(2) For that purpose I had recourse to the laws of induction, by means of which it is possible to detect the introduction of electric charges into the interior of a closed electric conductor, and to measure them. I therefore caused the cathode rays to pass into a Faraday's cylinder. For this purpose I employed the vacuum tube represented in Fig. 1. A B C D is a tube with an opening (a) in the center of the face B C. It is this tube which plays the part of a Faraday's cylinder. A metal thread soldered at S to the wall of the tube connects this cylinder with an electroscope.

E F G H is a second cylinder in permanent communication with the earth, and pierced by two small openings at β and γ; it protects the Faraday's cylinder from all external influence. Finally, at a distance of about 0.10 m. in front of F G, was placed an electrode N. The electrode N served as cathode; the anode was formed by the protecting cylinder E F G H; thus a pencil of cathode rays passed into the Faraday's cylinder. The cylinder invariably became charged with negative electricity.

The vacuum tube could be placed between the poles of an electro-magnet. When this was excited, the cathode rays, becoming deflected, no longer passed into the Faraday's cylinder, and this cylinder was then not charged; it, however, became charged immediately the electro-magnet ceased to be excited.

In short, the Faraday's cylinder became negatively charged when the cathode rays entered it, and only when they entered it; the cathode rays are then charged with negative electricity.

The quantity of electricity which these rays carry can be measured. I have not finished this investigation, but I shall give an idea of the order of magnitude of the charges obtained when I say that for one of my tubes, at a pressure of 20 microns of mercury, and for a single interruption of the primary of the coil, the Faraday's cylinder received a charge of electricity sufficient to raise a capacity of 600 C. G. S. units to 300 volts.

(3) The cathode rays being negatively charged, the principle of the conservation of electricity drives us to seek somewhere the corresponding positive charges. I believe that I have found them in the very region where the cathode rays are formed, and that I have established the fact that they travel in the opposite direction, and fall upon the cathode. In order to verify this hypothesis, it is sufficient to use a hollow cathode pierced with a small opening by which a portion of the attracted positive electricity might enter. This electricity could then act upon a Faraday's cylinder inside the cathode.

The protecting cylinder E F G H with its opening β fulfilled these conditions, and this time I therefore employed it as the cathode, the electrode N being the anode. The Faraday's cylinder is then invariably charged with positive electricity. The positive charges were of the order of magnitude of the negative charges previously obtained.

Thus, at the same time as negative electricity is radiated from the cathode, positive electricity travels towards that cathode.

I endeavored to determine whether this positive flux formed a second system of rays absolutely symmetrical to the first.

(4) For that purpose I constructed a tube (Fig. 2) similar to the preceding, except that between the Faraday's cylinder and the opening β was placed a metal diaphragm pierced with an opening β' so that the positive electricity which entered by β could only affect the Faraday's cylinder if it also traversed the diaphragm β'. Then I repeated the preceding experiments.

When N was the cathode, the rays emitted from the cathode passed through the two openings β and β without difficulty, and caused a strong divergence of the leaves of the electroscope. But when the protecting cylinder was the cathode, the positive flux, which, according to the preceding experiment, entered at *B* did not succeed in separating the gold leaves except at very low pressures. When an electrometer was substituted for the electroscope it was found that the action of the positive flux was real but very feeble, and increased as the pressure decreased. In a series of experiments at a pressure of 20 microns, it raised a capacity of 2,000 C. G. S. to 10 volts; and at a pressure of 3 microns, during the same time, it raised the potential to 60 volts.[3]

By means of a magnet this action could be entirely suppressed.

(5) These results as a whole do not appear capable of being easily reconciled with the theory which regards the cathode rays as an ultra-violet light. On the other hand they agree well with the theory which regards them as a material radiation, and which, as it appears to me, might be thus enunciated.

In the neighborhood of the cathode, the electric field is sufficiently intense to break into pieces (into ions) certain of the molecules of the residual gas. The negative ions move towards the region where the potential is increasing, acquire a considerable speed, and form the cathode rays; their electric charge, and consequently their mass (at the rate of one valence-gramme for 100,000 Coulombs) is easily measurable. The positive ions move in the opposite direction; they form a diffused brush, sensitive to the magnet, and not a radiation in the correct sense of the word.

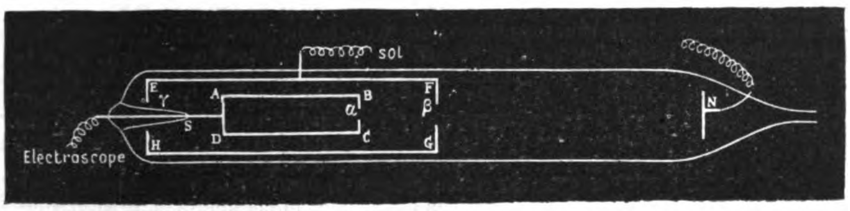

FIG. 1.

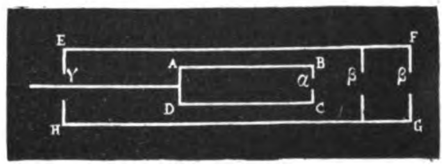

FIG. 2.

A 6,000-VOLT MEETING.

A 6,000-volt meeting of the directors was held at the Nelson Electric Light Company's power house yesterday, says the Juneau (Alaska) "Morning Record." The current became so strong at one time that two temper switches burned out with a flash of blue flame and it was found necessary to shut off the circuit with a shovel. Some important move must be contemplated, as two directors were observed going to bank very hurriedly.

AN EDDY PLANT AT BANGOR, ME.

J. N. V. Lane, the Bangor electrician, is now completing an important contract, the installation of a private lighting plant for the large woodworking establishment of Morse & Co., on Valley avenue, this city. The plant is entirely separate from the other machinery of the mill, the dynamo, a 300-light direct current "Eddy," manufactured by the Eddy Electric Manufacturing Company of Windsor, Conn., being run by a separate engine. Mr. Lane has connected 200 lights throughout the mills, under control of a slate swichboard. The plant works admirably.

[1] Translation of a paper by M. Jean Perrin, read before the Paris Academy of Sciences on Dec. 30, 1895.

[2] These vibrations might be something different from light; recently M. Jaumann, whose hypotheses have since been criticised by M. H. Poincaré, supposed them to be longitudinal.

[3] The breaking of the tube has temporarily prevented me from studying the phenomenon at low temperatures.

[4] This work has been carried out in the laboratory of the Normal School, and in that of M. Pellat, at the Sorbonne.

ON THE PRESENT HYPOTHESES CONCERNING THE NATURE OF ROENTGEN'S RAYS.[1]

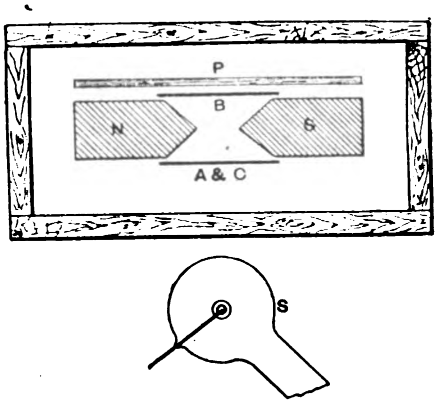
BY DR. OLIVER LODGE, F.R.S.

Until recently I was still uncertain whether Röntgen rays might not experience a trace of deflection in a strong magnetic field; and this, notwithstanding the assertion of the discoverer that he had found no deflection. No details of the experiment had been given, and although it might seem safe to trust the bare assertion of so known an experimenter as Professor Röntgen, yet, on account of the portentous gravity of the issue, I felt bound to satisfy myself by a direct confirmatory experiment. If only there were a magnetic deflection of the rays, the very simplest of all possible hypotheses would be confirmed—the hypothesis, viz., of a kind of sound-pulse conveyed by electrified particles, streaming on the whole in one direction, with interchanges of energy, passing on the motion in a Grotthüs-chain kind of fashion, but passing it on by simple material impact; a kind of electrolytic radiation, as I have expressed it.

My first experiment on magnetic deflection, the shadowgraph of a magnet with a background of wire-gauze, only showed that if there were any shift by reason of passage of rays between the poles it was very small; but I have now definitely to assert that a further experiment has been made which effectually removes the idea of deflectibility from my mind, and confirms the statement of Professor Röntgen.

A strong though small electromagnet, with concentrated field, had a photograph of its pole-pieces taken with a couple of wires, A and C, stretched across them on the further side from the plate—nearer the source—and a third wire B also stretched across them, but on the side close to the plate. (See Figure.) These three wires left shadows on the plate, of which B was sharp and definite, while A and C were blurred.

A couple of radiographs were taken by Mr. Robinson, one with the magnet on, and one with the magnet reversed. On subsequently superposing the two plates, with the sharp shadows of B coincident, the very slightest displacement of shadows A and C could have been observed, although those shadows were not sharp. But there was absolutely no perceptible displacement, the fit was perfect. Consequently the hypothesis of a stream of electrified particles is definitely disproved; as no doubt had already been effectively done in reality by Professor Röntgen himself.



But it must be noted that the hypothesis of a simple molecular stream—not an electrified one—remains a possibility. The only question is whether such an unelectrified bombardment would be able to produce the observed effects. In so far as it could affect photographic plates one would suppose it must be by means of phosphorescence, but it is doubtful whether it would even have the power of exciting phosphorescence.

It must be remembered that Dr. Lenard found among his rays two classes as regards deflectibility—some much deflected, others less deflected; and it must be clearly understood that his deflections were observed, not in the originating vacuum tube, where the fact of deflection is a commonplace, but outside, after the rays had been as it were "filtered" through an aluminum window. He did not, indeed, observe the deflection in air of ordinary density, it was in moderately rarefied air that he observed it, but he showed that the variation of air density did not affect the amount, but only the clearness of the minimum magnetic deflection. The circumstance that affected the amount of the deflection was a variation in the contents of the originating or high-vacuum tube.

The hypothesis, therefore, that naturally suggests itself is that the highly-charged particles flying from the cathode deliver up the greater part of their charges when they reach the aluminum window, and that the outside particles which take up the running are less charged, some of them perhaps not charged at all. These last would not be so likely to excite phosphorescence, hence Lenard would not perceive them; he would only observe those that had managed to retain or acquire a modicum of charge, and these would be deflected.

The question has still to be asked, therefore, whether the rays discovered by Professor Röntgen, which are not at all deflected, are those which possess no trace of charge.

Besides, it must be remembered that the absence of deflection has only been proved in ordinary air, while the presence of magnetic deflection has only been proved in somewhat rarefied air; the investigation into this matter is not finished until a further experiment is done—viz., to verify the non-deflectibility of the Röntgen rays even in a fairly good vacuum.

So much for what remains of the almost defunct radiant-matter hypothesis (defunct only, be it understood, for the particular kind of rays studied by Professor Röntgen; and not really defunct for them, but in a state of suspended animation. The hypothesis of a bombardment of uncharged particles I have by no means yet abandoned).

The alternative hypothesis, as generally conceived, is some form of waves. True, no absolute necessity has been yet made out for a periodic disturbance traveling at a finite speed; but the circumstance that fluorescent materials are excited, and chemical action precipitated, suggests a periodic motion not altogether out of time with the vibration-frequency of molecules.

Let us grant, then, that this circumstance renders it likely that the cause of the Röntgen effects is to be sought in some kind of wave-disturbance in the ether. The next question that arises is, Is it of the nature of etherial light or of etherial sound? Is it such transverse or electrical vibrations as are obedient to the equations of Maxwell, or is it a mode of longitudinal disturbance requiring some generalization or modification of those equations in order to express it?

On the principle that we are bound to apply the simplest hypothesis until it can be shown to be insufficient, it is necessary to consider how far the hypothesis of transverse or electrical vibrations can be made to serve. The chief difficulty here is the transparency of electrical conductors. To Maxwell's waves, i. e., the light of every kind, they ought to be opaque. But already the translucency of gold leaf has been a slight known difficulty in the same direction, and it has been shown that by postulating interstices or lack of homogeneity, i. e., a structure not infinitely fine-grained with respect to the size of light waves, the difficulty can be more or less satisfactorily overcome. Why not, then, assume that these new waves are much smaller than any hitherto known? Why not assume that they compare closely in size with the atoms themselves? Indeed, if they compare in frequency, they must compare also in size if they are transverse waves, for the only pace at which such waves can travel through the ether is accurately known. That there is plenty to be said for this hypothesis is obvious from the fact that it appears to commend itself both to Professor Schuster and to Professor Fitzgerald. Among other things that can be said in favor of it are the following: Electrical oscillations in conductors are known to have the power of exciting light-waves, hence light-waves may be expected from electric oscillations or surgings in atoms; but visible waves are not so excited. Visible light appears to be due to something more like the sound-vibration of atoms, as if they were bells or plates struck and made to vibrate. Bells and plates of atomic size would vibrate at about the required pace, viz., 400 to 800 million vibrations per second.

But electrical or Hertz-like oscillations of a charge on conductors of atomic size would vibrate immensely faster, being controlled not by the rate at which sound travels across an atom, but by the rate at which light travels, and this is just about 100,000 times as quick. Hence, as has often been pointed out, electrical oscillations in atoms are too quick for light; but yet they must occur, one would think, when atoms are being violently disturbed and charged and discharged; and if ever such oscillations occur, transverse waves must be emitted. Why should not these constitute the Röntgen rays?

This matter of the extra-rapid ultra-ultra-violet light may be safely left in the hands of its supporters. Its great advantage is that it utilizes no new or unknown property of the ether—nay, more, it utilizes a disturbance which, although not yet otherwise discovered, must naturally be assumed to exist, unless definite reason is shown against it. It is needless to emphasize further the high probabilities in favor of this hypothesis. Such statements as there are against it will follow incidentally.

Now we come to the last hypothesis, the one suggested by Professor Röntgen—the one which commands the high support of Professor Boltzmann—the one which it is not too rash

[1] London "Electrician."

to assume is regarded not unfavorably by Lord Kelvin,[1]—viz., the hypothesis of etherial sound or longitudinal waves in the ether. The only facts hitherto assumed to utilize longitudinal or pull-and-push properties in the ether are the facts of gravitation and of cohesion. Newton himself showed that an etherial tension or pressure would account for gravitation. Nothing is known about these properties, and there are difficulties in supposing that the ultimate space-filling medium can be really compressible. It is not, indeed, necessarily compressible to account for cohesion and gravitation, but it must either be compressible, or else simulate the effects of compressibility, if it is to transmit a periodic or atom-shaking disturbance at any finite pace.

Assume for the moment a slight compressibility of some sort, and consider what occurrences there are in a well-exhausted vacuum tube which could start longitudinal waves in such a medium. We have in the vacuum tube a violent torrent of atoms striking on the glass. Suppose that the vacuum is about 10^{-6} of an atmosphere—which appears to be something like that needed to give good effects—then the distance apart of the residual atoms in the exhausted space is a hundred times as great as in ordinary air, and a thousand times as great as in liquids; hence the distance will be about 10^{-5} cm.; or each spot of glass will receive a hundred thousand blows from every centimeter length of the stream to which it is subjected. But the speed of the cathode rays has been directly measured by J. J. Thomson as something comparable to 10^7 cm. per second. Hence the glass will be struck on the average, at every point, 10^{12} or a billion times a second, by the mere procession of negatively-charged atoms. It is easy for this estimate to err by a factor 10, and it is also easy for places to be sometimes struck ten times more frequently, by reason of the above estimate being only an average. Hence it may be surmised that the frequency of luminous vibrations is occasionally reached, and the glass not only grows hot but also shines.

It is probably quite unnecessary to appeal to this rapidity of bombardment in order to account for visible fluorescence, but the rapidity of bombardment is of interest because in any compressible medium such rudely periodic disturbances could hardly help starting some kind of sound waves.

But, besides that, the atoms themselves are known to be elastic, and to have definite periods of vibration like plates or bells, as evidenced by their spectroscopic lines; hence the blows to which they are subjected must be thought of as likely to excite vibrations or crispations in them. The frequency of these are such as to emit luminous waves in an ether possessing electromagnetic properties, the atoms being charged; but if they occur in an ether which is anything like a compressible fluid, how can they avoid exciting mechanical or sound waves too?

Nothing can be known for certain about the wave-length or velocity of such waves in ether until an interference or diffraction experiment has been performed, but the order of magnitude of the frequency can be taken as that of light, say 10^{15} per second, or quicker. The only way at present to gather some idea of the wave length is to attend, (a) to the sharpness of the shadows, (b) to the thickness of medium which is effectively opaque.

The longer the wave the more transparent are things likely to be, because waves are always damped out logarithmically, and this needs a certain number of swings, or at least a certain fraction of a swing, for notable damping to occur. A wave a yard long is not likely to be effectively stopped by an obstacle an inch thick. Without a knowledge of the damping-ratio, however, no numerical estimate can so be made, but a better estimate can be got from the sharpness of shadows. Take a point source, and investigate the outline of the shadow of an object held at a moderate distance from the screen or sensitive plate. No clear shadow will be thrown when the size of the obstacle is comparable to a wave length, if its size is small, or when it is removed several wave lengths from the plate, if the size of the obstacle is large. For, in wave theory, shadows are thrown by interference; and diffraction effects become prominent even when a want of precision about the source hinders the recognition of any clear diffraction pattern. The latter would not only indicate the wave length, but measure it. Short of that an estimate can be hoped for. Mr. A. W. Porter, in Professor Carey Foster's laboratory, has obtained the sharpest radiographs I have yet seen, and he has the best chance of getting the data for an estimate. Suppose for the moment we guess that a wave length of about 1c m. is not unlikely, then the speed of the hypothetical longitudinal waves would be of the order 10^{15} cm. per second, or more, i. e., about as much quicker than light as light is quicker than sound.

Such waves if they existed might be reasonably styled gravitational waves; for although gravitation does not need any wave propagation, only a state of statical stress or tension, yet it would be the rate at which the tension traveled outward if a fresh piece of matter started existence, or probably if an old piece of mater moved about with sufficient rapidity. Such motion would appear likely to entail aberrational effects, but aberrational questions are notoriously difficult, and the subject is only here mentioned because it is doubtful whether the Laplacian difficulty would be felt in astronomy if gravitation traveled a million times as quick as light. The pull of the sun would be felt in the time that light needs to travel 92 miles, and this is nearly instantaneous; or, otherwise, the terrestrial aberration-angle for gravity would be only the hundred-thousandth part of a second of arc.

But what about the Cavendish-Faraday-Maxwell experiment? that experiment which is held to establish the incompressibility of the ether, or the electrostatic law of inverse square, or the impossibility of a free or isolated electric charge (see "Modern Views of Electricity," Second Edition, pp. 9, 11, 29, 31-34, 257). We cannot tell what the volume-elasticity of the ether has to be, in order to transmit condensational waves of the above speed, unless we know its density. Dr. Larmor has shown some reason for supposing that ether may be as dense as platinum. If it be anything like that, and if the longitudinal wave velocity is 10^{18}, then the incompressibility is more than 10^{30} C. G. S. units; too great for any such experiment to show.

The object of mentioning these matters here is to help to realize that there is nothing in present knowledge obviously fatal to the idea of longitudinal waves in the ether; but the arguments in their favor, in connection with Röntgen rays, remain to be given. Assuming wave propagation of some kind, every argument against tranverse is in favor of longitudinal, and vice versa.

Now the thing that suggested longitudinal waves to Röntgen was the fact that crystalline properties were of no importance: e. g., that Iceland spar and quartz were equally transparent or opaque whichever way you turn them. But it must be admitted that such a test as that is next door to none. If tourmaline is transparent to Röntgen rays going along its axis it would be a much better test; and this I have myself ascertained to be the fact. J. J. Thomson also has found that a pair of ordinary cut tourmalines are equally transparent whether their axes are "crossed" or parallel; which is an excellent test. Nothing suggestive of polarization in any form has yet been observed; a fact which tends against transverse and in favor of longitudinal waves. But the strongest argument in favor of longitudinal waves is derivable from the fact that the rays discharge electrified bodies. Lenard found this, and J. J. Thomson and I have both obtained it easily under Röntgen-like conditions; but their peculiarity is that (unlike light) they discharge positive and negative about equally.

Now, Elster and Geitel showed that when polarized light discharges a really smooth surface it is most effective when the electric oscillation is partly normal, not tangential, to the surface; in other words, that it is what may be called the longitudinal or end-on component of ordinary light that is by far the most effective in discharging electricity.

Mr. Robinson thinks he has observed that the same thing is true as regards the power of exciting fluorescence; an important observation if true, but the examination is not complete yet. If it turns out so, then the two things that Röntgen rays are known to do are characteristic of end-on or normal vibrations.

As to the photographic or radiographic action, it is so slow and inadequate at present that it hardly looks like a direct primary effect, but even there it seems as if thick films did better than thin.

Another fact that gives a gravitational look to Röntgen's rays is the fact that they appear to pay more attention to specific gravity or ordinary density than to any other property of matter. This can be said without stating that opacity and density are strictly proportional. Any way, electrical properties of matter seem to be quite unimportant; polish or roughness, a coherent block or a powdered mass, are all the same to these waves, as they are to gravity.

Direction of crystallization matters nothing, nor does shape; an aluminum prism cannot bend them; they cannot be bent or even reflected to any considerable extent. If it be found that physical state is also unimportant, so that the same molecules obstruct equally however they be aggregated, whether

[1]In this connection it is interesting to refer to Lord Kelvin's Presidential Address to the Royal Society, Nov. 30, 1893 (Harrison & Son, London), on the subject of Hertz-waves and Radiant Matter, in which he confidently anticipates further progress and gives an interesting résumé of the history of highly exhausted vacuum-tube effects in connection with the subject. He emphasizes the important part played by Cromwell Varley in 1871, before either Bittorf or Crookes, in the discovery of cathode rays and strongly supports the material view, in opposition to many continental workers.

into solid, liquid or gas, that will be a further contribution to the evidence in the same direction.

Thus there is plenty of scope for experiment. A few weeks may be sufficient to intensify our conviction in one or other of the already-mentioned directions, or we may find ourselves urged by new facts in some other direction not yet thought of.

In conclusion, let it be remembered that Lenard, Hertz, Goldstein and the Germans generally (except Helmholtz—a notable exception!) have consistently urged that cathode rays were something more than a stream of particles; in case it should so turn out, Lenard urged this for his rays outside, in air. Hertz, I believe, urged it for the rays inside the vacuum. It may be that the streaming particles are there, but an ethereal process may be also there. Outside in the Lenard rays both processes possibly coexist, one deflectible by a magnet, the other not. That both processes exist also inside the vacuum is not likely. J. J. Thomson has exposed a protected plate in the very rays themselves inside the vacuum and got no result. It looks as if the streaming particles alone could not achieve it.

If the sun emits any rays that can reach photographic plates through boxes or hand bags, even through black paper, every touring photographer should know; but if cathode rays alone have no direct action, without the intervention of a phosphorescent substance, then even the absence of direct solar action would constitute no valid and conclusive proof that the coronal rays are not electrical, though it would very much militate against a method of easily obtaining a photographic record of the corona which has been suggested.

ROENTGEN RAYS DISSIPATE ELECTRIC CHARGES.

The following letter from Professor J. J. Thomson appears in the London "Electrician" of Feb. 7, 1896: "Those of your readers who are making experiments on Röntgen's rays may perhaps be interested in a method of testing their presence which is more delicate and expeditious than a photographic plate, and also more easily adapted to quantitative measurements. It is simply a charged insulated metal plate. I have found that when this is exposed to Röntgen's rays it rapidly loses its charge, and the test is so delicate that I have by this means been able to detect the rays after their passage through a zinc plate ¼ inch thick. The leakage caused by these rays differs materially from that investigated by Elster and Geitel and due to ultra-violet light. In the first place the Röntgen rays discharge positive as well as negative electricity, and secondly, the leakage goes on even when the electrified plate is embedded in paraffin, ebonite, mica, sulphur, etc. This shows that all substances through which the Röntgen rays are passing become for the time conductors of electricity. This result seems to me very suggestive both as to the nature of the rays and also of the conduction through the insulator."

AN ELECTRIC LIGHTSHIP FOR THE BOSTON STATION.

The first electric lightship built in this country is the one now on a Connecticut station; the second is building, and she will be known as light vessel 66. By an odd coincidence in figures her contract price is $66,000. She is for the Boston station and will be launched some time in April. This torch-bearing vessel is of composite construction, wood and steel entering about equally into her hull, this build being more durable, easier to take care of, and safer in case of grounding than one of all metal. Her dimensions are: Length, 66 feet; breadth, 28½ feet; depth, 13 feet.

From the masthead two bunches of red light will warn the mariners of dangerous water. There will be four 110-volt 100-candle-power lights at each masthead, enveloped in red glass, which will be about 43 feet above sea level. The extreme length of her masts will be 67 feet, including an 11-foot topmast on each. The masts will be made of iron 16 inches in diameter at the thickest part. Wire rigging will be used, and enough sail will be bent on to give her steerage way in case she is torn from her anchorage.

In addition to a spread of canvas the lightship will be equipped with a 300-horse-power engine, two boilers of the Scotch type, 300-horse-power each, and two donkey engines for hoisting purposes. Her screw is four-bladed, eight feet in diameter, and of composition. She will be moored with a 5,000-pound anchor. The vessel will be equipped with two lifeboats and additional anchors, a powerful steam siren for whistle, and a 1,000-pound bell. A mate to this vessel is being built in San Francisco for use on the Pacific coast.

X-RAYS IN OPERA GLASSES.

A loud laugh went over the State of New Jersey on Feb. 19, when Assemblyman Reed, of Somerset County, introduced a bill in the House, at Trenton, prohibiting the use of X-rays in opera glasses in theaters.

LETTERS TO THE EDITOR.

THE N. E. L. A. STANDARD RULES ON CONSTRUCTION AND OPERATION.

On behalf of the Committee on Standard Rules for electrical construction and operation of the National Electric Light Association, I take pleasure in sending you herewith a statement as to the present condition of the work undertaken by that committee for the forming of a joint committee, composed of the various electrical, insurance and allied interests, which joint committee, it is proposed, shall take up the most important matter of the codification, promulgation and enforcement of one standard set of rules which shall meet as fully as possible the conditions that now exist, be up to date, and prove acceptable to the various interests affected by electrical construction work.

The following organizations were invited to co-operate, and our committee is most pleased to state that in every instance the invitation extended has been accepted, and in the appended list is given the names of the delegates appointed to represent those various organizations; and the character of the appointments made is in every case so high as to guarantee a most careful consideration of the important questions to come up and their treatment in an able and conservative manner. The list of those who have been invited to co-operate with our committee, together with their delegates, is as follows: American Institute of Electrical Engineers, Professor Francis B. Crocker, Columbia College, New York; American Street Railway Association, John A. Seely, Consulting Electrical Engineer; National Board of Fire Underwriters, William H. Merrill, Chief Electrician, Chicago, Ill.; Western Union Telegraph Company, A. S. Brown, Chief Electrician, New York; Postal-Telegraph Company, Francis W. Jones, Chief Electrician, New York; American Institute of Architects, Alfred Stone, Secretary, Providence, R. I.; National Association of Fire Engineers, Captain William Brophy, Electrical Expert of the Commissioners of Wires Department, City of Boston, Mass.; American Bell Telephone Company, C. J. H. Woodbury, of the Engineering Staff, Boston, Mass.; General Electric Company, Lieut. S. D. Greene, General Manager Lighting Department, New York; Westinghouse Electric and Manufacturing Company, Charles F. Scott, Electrician, Pittsburg, Pa.

The committee of the National Electric Light Association who have had charge of the standard rules of that association for a number of years, and who have taken the initiative in the forming of the joint committee, are as follows: William J. Hammer, Chairman, Consulting Electrical Engineer, New York; James I. Ayer, Consulting Electrical Engineer, Boston, Mass.; Harrison J. Smith, General Operating Superintendent Edison Electric Illuminating Company, New York; E. A. Leslie, Vice-President and General Manager Manhattan Electric Light Company, New York City; Capt. William Brophy, Electrical Expert of the Commissioner of Wires of the City of Boston, Mass.

In view of the various misconceptions of the committee of the National Electric Light Association and of the joint committee, it will not be out of place to state that the various associations have been invited to send a delegate to the joint conference, on March 18, but not in any way was it intended to commit them to any definite action at the meeting. It is proposed that the various rules which have been promulgated by the various interests, electrical and insurance, shall be taken up for consideration and thoroughly discussed from the standpoint of the various interests represented at that meeting, with a view of forming a new code comprising the best that is in the various sets of rules now in vogue, and new matter considered advisable; that the delegates should take part in the discussion and vote upon the various matters which would come up bearing upon the importance and value of the rules submitted, and after a code has been prepared which has met with the approval of the various delegates attending the meeting, that the code thus prepared should be submitted by the various delegates to the bodies which they represent with the intention that they shall ultimately, if it is deemed advisable by the various national organizations, be approved by them. And, as stated before, it is not the intention that the questions taken up in the discussion shall commit the various organizations to any definite decision in this matter at this meeting or thereafter, if they should deem it inadvisable to co-operate.

It seems almost unnecessary to call attention to the paramount importance of securing the adoption of one single standard set of rules. Examine the condition of things which exists to-day, in which we have the code of rules issued by the National Electric Light Association, which, as is well known, are largely the basis of all the rules used in the United States; the code adopted by the National Board of Fire Under-

writers; the rules issued by the various illuminatting companies; the rules of the Manufacturers' Mutual, of the New England and similar associations; the rules now about to be issued of the Fire Department of the City of New York. and similar organizations in other cities, the independent sets of rules prepared by consulting engineers, insurance experts, etc., which are more or less in vogue in the United States. Unquestionably, the existence of these various rules, which are all of them of greater or less intrinsic value and importance, leads to a tremendous amount of confusion, misunderstanding, expense, litigation, and I think will be generally admitted frequently to the interpretation and enforcement of the various rules largely in accordance with the personal views of the local inspectors. By securing the adoption, promulgation and enforcement of one single standard which will meet with the approval of the various electrical, insurance and allied interests, and which rules shall be the result of the joint action of these various interests and not be fathered by any particular association, electrical, insurance or otherwise, we shall arrive at a condition of things which has been hoped for and worked for for many years past. It seems, then, as the preliminaries for the proposed joint meeting have been so successfully inaugurated, that it is the duty of not only the various organizations, which are co-operating at this joint meeting, but electrical and insurance men, and those connected with allied interests to lend every assistance and encouragement in their power to secure the aimed at and much to be desired result of the adoption of a single National Code of Rules.

On behalf of the preliminary committee of the National Electric Light Association, who are arranging the details of the meeting which is to be held on the 18th of March (and probably on the 19th as well), I wish to extend an invitation to any one to send, either to my address or to Mr. George F. Porter, Secretary of the National Electric Light Association. 136 Liberty street, any criticism or suggestion upon any of the rules now in vogue or matter which might be included in the proposed new code.

In conclusion, I take pleasure in stating that the American Society of Mechanical Engineers have extended the courtesy of the use of their headquarters at No. 12 West Thirty-first street, for the holding of the proposed joint meeting, on March 18 and 19, 1896.

WILLIAM J. HAMMER,
Chairman National Electric Light Association Committee.
Havemeyer Building, New York City, Feb. 20, 1896.

MAGNETIC CUT-OUTS.

Your editorial of Feb. 5, and advertisement relating to magnetic cut-outs, together with a published article showing the slow and unsatisfactory action of fuse metals for heavy currents, were all most interesting. Letters to your valuable paper from Mr. Walter E. Harrington and the writer have, in view of what was so ably pointed out, argued that for traction work fuses were of little, if any, value, and that the heavier their work the more unsatisfactory they were. For cases like the Metropolitan West Side Elevated Railway, in Chicago, the Nantasket Beach Railway, in Massachusetts, or similar ones, they would be wholly useless, as we then pointed out.

Mr. Harrington complained that the blistering of the contacts, due to arcing, has been urged as a serious objection to the use of magnetic cut-outs. He suggested one simple and easy method of overcoming this and the writer another. The cuts in the advertising columns suggest a third, which seems to be the best. These appear to show a simple design in which there is first a metallic break, followed by an opening of the circuit between two carbon contacts, thus throwing the arc upon the carbons where its damage will be slight. Whether or no this be the method illustrated (which one can only guess at in the absence of description) it appeals to me very strongly as a traction engineer. Being one of the pioneer electricians of the now national institution, the trolley system, who shared the great and at times discouraging difficulties of its early development, one can doubly appreciate the value of such a cut-out. For trunk line branches, of which the writer is laying out work for some, one could hardly devise anything better.

Having thus minimized the effects of arcing upon the contacts of the cut-out, the adjustment of the magnet, so as to open the circuit the instant the current exceeds a specified value, is a mere matter of design and workmanship.

JAMES H. BATES.
New York.

OF THE GREATEST VALUE AS REFERENCES.

Permit me to testify to the very great value of the leading article in your number of Jan. 8, describing in very considerable detail the large station of the local Edison Company. Articles of this kind, which are quite frequent in your journal, not only aid one in keeping informed of what others are doing, but are of the greatest value afterwards as references in case it is desired at a later date to do any work of a similar kind or to collate information in regard to a particular subject.

Wishing you still further success, even in the mature development of your valuable journal, etc.,

New York. CHAS. E. EMERY.

THE BEST OF ITS KIND.

I consider the article on the Edison station the best of its kind that I have yet seen, as regards lucidity and comprehensiveness, and, especially perhaps, as regards the clearness and general excellence of the illustrations, which, to my mind, are in every way admirable; strikingly so, indeed, when compared with the bulk of plate illustrations, which have been appearing of late, and in which, in numerous cases, even an expert would be puzzled to designate the alleged apparatus. You have certainly placed the electrical profession under obligations in the production of so valuable a contribution to the literature on central stations, and I am sure it is fully appreciated. Wishing you continued and increasing success,

New York City. WM. MAVER, JR.

THE VIENNA AIR CHAMBER RAILWAY CONDUIT.

Your issue of Jan. 29 contains an article under the head of "The Air Chamber Conduit in Vienna," referring to a system wherein a small conduit is used, the trolley wires being supported in an air trap so that the water cannot reach them. You erroneously credit this invention to Mr. R. W. Barkley, of New York. This scheme was patented by the writer in the United States and numerous foreign countries (including Austria) about ten years ago. Notice the fundamental claims 7 and 8 in my United States patent, No. 345,845, of July 20, 1886. I mention this merely as a matter of history.

J. C. HENRY
Denver, Colo.

NEWS AND NOTES.

EXAMINATION OF NEW YORK ELECTRICIANS.

Assemblyman Trainor has introduced in the New York Legislature a bill providing for the appointment in each judicial district of the State of a board of electrical examiners. It provides that four persons shall be appointed by the Governor in each district to comprise a board, to be charged with the duty of determining the qualifications of persons engaged in the installing or operation of electrical apparatus and appliances in buildings for light, heat and power. The board shall be bi-partisan and be empowered to collect not less than $3 and not more than $10 for each person examined and licensed. The members of the board shall receive $5 a day for each day's actual service.

THE MAGNETIC INFLUENCE OF THE PLANETS.

In the meteorological records of the St. Petersburg Academy of Sciences, Vol. XVII., there is an exhaustive discussion of the magnetic observations made at St. Petersburg and Pawlowski from 1878 to 1889, and their bearing on the influence of the various planets on the magnetic declination. From this it would appear that all the planets exercise a marked influence not only on the absolute value of the declination, but also on its diurnal variation. All the planets except Mercury increase when they are near the earth both the absolute value of the declination and the periodic portion of the daily variation. The extreme values of the declination differ in a year by 0'.85. Taking this amplitude as unity, the following numbers express the amplitude of variation corresponding to an entire synodic revolution of the respective planet: Mercury 0.58, Venue 0.61, Mars, 0.59, Jupiter 0.40, Saturn 0.12, Uranus 0.15, Neptune 0.27.

In the current number of "Nature" there is an interesting article by Professor A. Schuster, criticising this alleged magnetic influence. Professor Schuster thinks that "among the many improbabilities of magnetic influences which are hanging over us, that of a planetary effect may for the present be set aside."

THE CONDUCTIVITY OF ALUMINUM.—A CORRECTION.

In a letter addressed to Mr. G. L. Addenbrooke, and published in the London "Electrical Review," Lord Kelvin states that, owing to an absurd error, the conductivity of aluminum given by him was erroneous, and that his corrected figures show that the conductivity of aluminum does not differ materially from that given in text books and books of reference. Lord Kelvin's supposed corrected figure was given in our last issue, on page 196, which should therefore be disregarded.

CONTENTS.

THE WILSON-SQUIRE EDUCATION BILLS.

THE liberality of most of our State Governments in the establishment of universities has thus far made it less incumbent upon the general Government to inaugurate large educational undertakings, although measures of this nature have been more than once suggested, more particularly for certain sections of the country, especially the South. But that the Government possesses vast potentialities for aiding the present established institutions must be apparent, and we are glad, therefore, to note an earnest attempt to bring about a much needed addition to the naval engineering resources of the country. Bills have been introduced in the United States Senate and House, respectively, by Senator Squire, and Representative Wilson, to maintain courses of instruction in naval engineering in the several scientific and technological schools of the country, and so to endow and support such courses, as well as aid and strengthen the present engineering courses of all such institutions, that they may become recognized as proper fitting schools for the United States Naval Engineering Service. The engineering departments of the State and other colleges and universities are likewise included and benefited.

While the chief aim of these bills is to afford a means for increasing the staff of naval engineers, which the growing needs of the Navy has already overtaxed, the benefits which the measure, if adopted, will confer on engineeing schools in general is manifest. The extent to which electricity is now applied in the modern warship, as indicated, for example, in Dr. Park Benjamin's article on the "Nerves of a Warship," in "Harper's Magazine" for March, must necessarily require that special attention be paid to electrical engineering in a course adapted for the naval engineers. Hence the electrical profession at large will be directly benefited by the provisions of the bill. But leaving out of consideration all direct benefits, the fact that the supply of naval engineers is not equal to the demands at the present time, is sufficient to call for the passage of these bills as a matter of the first importance to the welfare and security of the country. Our readers may aid the cause of technical education by communicating with their representatives in both Houses of Congress, urging favorable consideration of these bills.

THE NIAGARA ENTERPRISE.

ONE more step forward in the Niagara power enterprise is to be noted in the announcement of a contract for the poles which are to be used in the transmission line from the Falls power house to Buffalo. A further point of interest is the fact that the poles will be wooden. They will be Canada cedar, all 8 inches in diameter at the top, and ranging from 25 to 50 feet in length. They will be set ordinarily 50 to the mile, but where exposed to unusual wind strains, etc., 100 to the mile will be used. The poles will have two crossarms. The current, as already noted, is to be transmitted 3-phase from point to point.

Within the last week or two the wintry condition of the weather has interfered greatly with the flow of water over the Falls, and it is said that not since 1848 has there been a season when the Niagara River has so closely approached the state of the Red Sea when Pharaoh and his host essayed to

cross it. Some months ago, Mr. Andrew Green, one of the Niagara Reservation Commissioners, raised a shrill cry of alarm over the early coming of a time when the various utilizations of Niagara power would deprive the Falls of their beauty, because there would be no water left. It is evident that Nature, and not man, is the agency to guard against. Mr. Clemens Herschel, the distinguished hydraulic engineer, in a recent comment on such views, shows that if all the present work were carried out to an extreme and water capable of developing 400,000 horse-power were diverted, the sheet of water at the American Fall would be lessened from 4 feet to 3.74, and that of the Horseshoe from 14 feet to 13.08. The time is certainly rather remote when all this energy can find customers, but it might be a blessing if it could be used to-morrow. Professor Shaler, of Harvard, in pointing out that the Falls recede as rapidly as they do because of the eating out of the underlying soft strata, has suggested, first, diversion of part of the stream, and, second, the supporting by masonry of the superincumbent shelf of limestone over which the limpid water plunges. The first part of his programme of conservation is now being put in force; the second is worthy of consideration by those who wish to "save Niagara."

STORAGE BATTERIES ON ELEVATED RAILROADS.

FOR several years past the officials of the New York Elevated Railroad system have been reported as earnestly studying the question of the application of electricity to their system of transportation, and at last we are to have a trial of an electric system on one of the branch roads, running for a distance of less than of a quarter a mile. The New York Elevated has been harshly criticised in the past for having so long delayed taking up the subject, considering the examples of successful electrical operation of elevated railroads afforded by other cities, such as Chicago and Liverpool. Of course, the extenuating circumstance may always be cited that the changing about of an established system of steam locomotion, the abandonment of several hundred locomotives, and the investment of five or six millions of dollars in new equipment, are not to be lightly passed upon.

Now that the New York Elevated roads have again taken up the subject, it is interesting to compare the present proposed system with those which have preceded it. The first to undertake electrical work on the elevated roads, it will be remembered, was Mr. Leo Daft, who, in 1884, placed his locomotive, the "Ampere," on the Ninth avenue line. He was succeeded by Mr. Frank L. Sprague, with a car equipped with individual motors, practically the same system now in operation in Chicago and in Liverpool; and, again, Mr. S. D. Field attacked the problem with a locomotive of his direct connected crank type. The present experiment is noteworthy, in that while following the general lines of a motor car of the type which the World's Fair "Intramural" road made so familiar, it introduces the additional feature of a storage battery carried on the motor car. Of course, it is not contemplated that the storage battery will be used for anything more than as a regulator and as a temporary source of current in case of accident, or to bridge switching points; but the reasons which dictated the placing of the battery on the car in preference to installing it at the power station are worthy of full consideration. These reasons have been deemed of sufficient weight to induce the company installing the electrical equipment to undertake it with confidence in its successful operation, and the outcome of the experiment will be watched with the keenest interest by electrical and railroad engineers.

PACIFIC CABLE SCHEMES.

WE publish this week a report of the recent hearing in Washington, before the Senate Committee on the Pacific cable schemes. The situation is interesting and reveals a rivalry between English and American capital that is surprising to many people, though certainly not to any who have been watching the rapid development of affairs in the Far East. The Spalding plan is understood to have English enprise behind it, and proposes a cable to the Sandwich Islands from San Francisco, where, presumably, it would link into the British cable system that has been developing so persistently and so successfully in that part of the world. The Scrymser plan not only contemplates a Hawaiian cable, but reaches out to Japan and China. There it would presumably have to link on to the existing lines controlled by English capital. Col. Spalding has already his exclusive Hawaiian concession and is backed by well-known Americans, including Abram Hewitt, D. O. Mills, Col. Fred Grant and Gen. Wager Swayne; but this concession depends upon a subsidy from the United States. Mr. Scrymser claims that his company represents competition and lower rates by at least one half. The remarkable thing about this rivalry is that both plans appear to depend on a landing in the United States, whereas only a year or so ago the Colonial Conference meeting at Ottawa discussed seriously landing on British Columbian soil, and Mr. Alexander Siemens was himself in attendance to furnish the information of which a digest appeared at the time in these pages. It is evident, anyhow, that we shall soon have a Pacific cable, and it will be laid none too soon. The cost averages around $4,000,000, and as to subsidies Hawaii has already pledged $40,000 a year to Mr. Spalding and his associates for a cable to be laid not later than Nov. 1, 1898.

ROENTGEN RAYS.

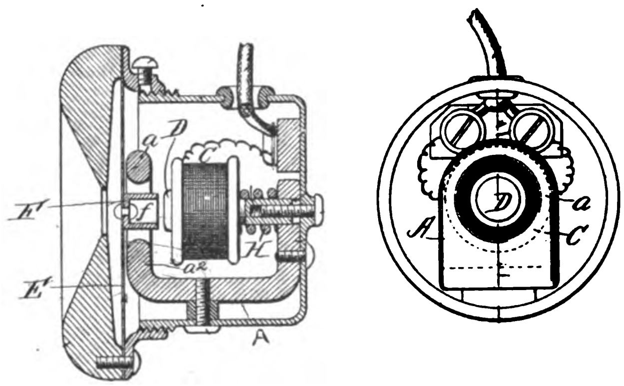
WHILE one may not always be in full accord with the views of Dr. Lodge, who is a radical in science, his statements are always interesting and contain much food for reflection. His review of the Röntgen ray theories which we print this week is an excellent digest of the subject, and his own experiments, corroborating the results of Professor Röntgen, indicate pretty clearly to our minds that the latter, like a true scientist, deliberated well and long before venturing before the public with his remarkable results. Perhaps the most interesting, not to say startling fact established since Professor Röntgen's publication is the announcement by Professor J. J. Thomson, that the X-rays dissipate the electrostatic charge of any body upon which they may fall, no matter how that body may be protected from discharge, and further, that the nature of the charge, whether positive or negative, is immaterial. It is this latter property which distinguishes the X-ray action from that of the ultra-violet rays discovered by Elster and Geitel, which have the power of dissipating but a negative electrical charge. We think that this property of the X-rays will find an important place in the establishment of the theory of the X-rays, and the corollary drawn by Professor Thomson that all bodies, when under the influence of X-rays, become conductors, may find application in science and in the arts.

TELEPHONY AND TELEGRAPHY.

PRATT AND ALLEN'S TELEPHONE RECEIVER.

MANY have been the efforts to increase the sensibility of the telephone receiver, with the result that the relative arrangement of magnet and diaphragm has received a large number of variations. One of the most recent attempts of this kind is that embodied in the receiver illustrated in the accompanying engravings, due to Mr. H. P. Pratt and H. A. Allen, of Chicago.

The primary object of the instrument is to approximately double the variation of magnetic disturbance caused by the vibration of the diaphragm, and to such end certain useful lines of force are caused to pass through synchronously varying air spaces which interrupt metallic circuit portions between the poles of a magnet. The metallic circuit portions are provided by the diaphragm and an armature thereon, and the air spaces, respectively, occur between the diaphragm and one pole and between the armature and the opposite pole. The air space between the diaphragm and adjacent pole is varied by the vibration of the part of the diaphragm, and synchronously therewith the air space between the armature and the adjacent pole is varied.



PRATT AND ALLEN TELEPHONE RECEIVER.

As will be seen, this magnet, A, is formed with an annular portion, a, which constitutes one of its poles. The helix C is arranged upon the opposite pole of the magnet, and the pole upon which the helix is thus arranged is formed by a soft iron core, D, attached to an arm of the magnet and arranged opposite the space which is circumscribed by the annular pole, a, of the magnet.

The diaphragm E is separated from the magnet and is arranged in front of the annular pole a of the magnet, and carries upon its rear side a small armature F, which is attached to the center of the diaphragm. This small armature is arranged opposite the pole D and made hollow, so that, while it can be made light, it can comprise sufficient metal to permit it to carry a suitable number of lines of force, and also have sufficient cross-sectional area to enable the diaphragm to carry an increased number of lines of force.

It will be seen that pole a is arranged in a plane which is parallel to the plane of the normally-quiescent elastic diaphragm and interposed between the diaphragm and the opposite pole of the magnet, and that the armature which is carried by the diaphragm is arranged to intersect the plane in which the pole a is positioned. Certain useful lines of force, therefore, pass through metallic circuit portions provided by the armature and diaphragm, and through air spaces which interrupt the metallic circuit portions and which are synchronously varied by the vibrations of the diaphragm carrying the armature. In this way, it is claimed, the magnetic disturbance is augmented and practically doubled, thereby greatly increasing the efficiency of the instrument.

DRAWBAUGH WANTS A TELEPHONE PATENT.

Daniel Drawbaugh and his representatives were before the Senate Committee on Patents at Washington, on Feb. 15, advocating the passage of a bill that will enable him to go before the Patent Office and prosecute his claim for a telephone patent from which he has been debarred by reason of the finding of the Patent Office that his invention was in use for more than two years before his application was filed. Drawbaugh contends that it was only in use as an experimental affair, and not commercially, as required by the law. His alleged invention is similar to those upon which the Berliner patents, now in the Supreme Court, are based.

THE PROPOSED HAWAIIAN CABLE-U. S. SENATE HEARING.

THE United States Senate Committee on Foreign Relations gave the proposed telegraphic cable propositions connecting the United States with the Hawaiian Islands and the Asiatic coast, a hearing, at Washington, on Feb. 19. The proposition of the New York Company, headed by James A. Scrymser, which is looked upon with favor by a number of the committeemen, was materially amended in a statement laid before the committee. In addition to its original plan of constructing a line to Japan by way of the Hawaiian Islands, the company now proposes to extend the cable to such other islands in the Pacific Ocean as may be selected, and to the Coast of China, making that one of the termini instead of the Island of Japan.

A concession of importance is made in the matter of rates for messages and the use of the line by the Government. The bonus asked is $150,000 for a period of twenty years, during which time the company agrees to transmit all Government messages free of cost, and after the termination of the period of twenty years, when the bonus shall also cease, the company binds itself to forever transmit Government messages over its cables free of all cost. The usual stipulations are set forth relative to the seizure and control of the cable by the Government in time of war or other emergency.

The rate for ordinary private messages between the United States and Japan and China is fixed at $1.25 per word, and on messages between the United States and the Island of Cahu, in the Hawaiian group, at 35 cents per word. Press rates are not to exceed one-fourth the rates charged for ordinary messages.

The company agrees, within ninety days after the approval of the act, to deposit with the Treasury of the United States, United States bonds to the amount of $100,000, as a guarantee of its good faith—such bonds to be subject to forfeiture in case the company shall fail to complete the line to Hawaii within eighteen months, and between Hawaii and Japan within three years.

President Scrymser, in a statement submitted to the committee, says that the only obstacle to the early and successful establishment of this cable is the so-called exclusive grant by the Hawaiian Government to Col. Spaulding. Mr. Scrymser called attention to the fact that this grant was subject to and became operative only through the action of the United States Government. The statement also emphasized the fact that the competing company asked the same bonus for a service that extended between the United States and Hawaii alone. The United States Government, in granting a subsidy to the Spaulding Hawaiian cable would, Mr Scrymser stated, be indirectly perpetuating an existing monopoly of cable communication with China and Japan, which it was the object of his company to destroy, it now costing $2.36 per word from New York to Japan, and $1.76 per word to China. The through rate of $1.25 from San Francisco to Japan and China was, Mr. Scrymser asserted, very much less to the people of the United States, and more advantageous to the general Government.

The company submitted to the committee a copy of a letter addressed to Abram S. Hewitt, to which the company had as yet received no reply, but which Mr. Scrymser stated, was proof of the statements of his company that there was a "strong English influence behind the Spaulding scheme, and that the United States is expected to make a contribution to a monopoly enjoyed by foreign companies in China and Japan, of which Sir John Pender is chairman."

The letter to Mr. Hewitt submits to that gentleman the substance of a conversation had between himself and Edmund L. Baylies, vice-president of the New York company, which, Mr. Baylies says, was reduced to writing in order that there might be no further misunderstanding. This letter states that Col. Spaulding, while in England, made a conditional contract for the manufacture of his Hawaiian cable; that when he returned he brought with him a letter from Sir John Pender to Mr. Hewitt asking the latter to organize an American company; that such company was organized, and invitations issued for subscription to its stock, the understanding of Mr. Hewitt being that so far as his subscription of 1,500 shares was concerned, Sir John Pender was to guarantee him (Hewitt) against loss.

These documents were laid before the committee for the purpose of showing, as Mr. Scrymser claimed, that the competing company, also seeking authority to build a cable, was not American in its origin, but was backed by English capital, controlled by English influence, and sought to kill off the competition in cable tolls between this country and China and Japan,. that the company which Mr. Scrymser was seeking to establish and maintain. No action was taken by the committee.

MISCELLANEOUS.

ELECTRIC HEATING.—II.[1]

BY W. S. HADAWAY, JR.

As bearing upon this subject I beg to quote from a recent letter from the American District Steam Company of Lockport, N. Y.

"We observe that you recognize the futility of electricity competing with steam for diffused heating on a large scale, but there is a wide field for electrical companies in connection with their exhaust. In blocks of buildings where power is required to run elevators, or for other purposes, the proprietors will run their own power if they have to do their own heating, but if the electric company can heat the building it can get the power at a good profit, and there is a profit in both heating and power.

"We have just constructed a heating plant for the Rochester (N. Y.) Gas and Electric Company, who are doing just this thing; they start off with 5,000,000 cubic feet of space to heat in manufacturing and business blocks, and secure the running of several engines in the same buildings. They supply the steam from their station in underground pipe and power by wire. They could not get the power without doing the heating."

Careful study of the question of multi-potential heat supply from both the engineering and business standpoints, can hardly fail to give the utmost confidence that results of the greatest value can be obtained along this line. A total fuel efficiency of 35 per cent. for combined low and high temperature heating is certainly obtainable, and probably a still higher efficiency may be secured from operations on a large scale. It is in this connection that I look for the best immediate results of electric heating in domestic life. The electrical engineer of to-day realizes that the ordinary light and power station is extremely wasteful as a heat generator and distributor, and the only way to improve these conditions is to introduce a basis of supply in which the load factor is a larger percentage of the station capacity and in which what are now wasteful by-products may be utilized. This feature should receive the greatest possible care; space does not permit a discussion of Crompton's valuable paper on this subject and its practical bearings on the conditions existing to-day in this country, as shown by the reports of the Massachusetts Board of Gas and Electric Light Commissioners and the data collected by the National Electric Light Association.

Aside from electricity for cooking we find in the modern apartment houses a comparatively high distributive heat efficiency. The rooms are heated by steam, as is the water for bathing and cooking purposes. Electric lighting is available, but low heat efficiency is found in cooking, except in cases where gas is available. I do not question the value of gas for fuel in cooking; I take the ground that when a boiler plant is required for room and water heating and the electric plant for lighting, the use of gas in cooking is unnecessary and comparatively expensive. In these houses electricity is already being used instead of alcohol lamps for heating chafing dishes and small tea kettles for five o'clock tea, also for heating curling irons, sad-irons for laundry work and pressing, etc., and it appears to be a question of but a short time before electric ovens, broilers, and small portable stoves will replace the range or gas stove on a considerable scale. The apartment house supplied with its own boiler and electric lighting plant approaches more closely the proper conditions for electric heating than any other mode of domestic life, as all the conditions essential to economical working are already present.

The foregoing deductions have been introduced to indicate broadly wherein the true economical basis of electric heating lies. Like all general considerations, they are qualitative rather than quantitative in character. We find in industrial and commercial practice a great number of heat applications, either at high or moderate temperatures, in which close regulation and facility of control are necessary and where electric heating on some scale is applicable. The introduction of electric lights and motors has brought into use in central stations and isolated plants a vast amount of electrical generating apparatus, so that at the outset our problem is almost wholly one of applying electric heating apparatus on circuits already established, primarily for other purposes. On these circuits we are usually able to show apparatus to do the work required better than it is at present accomplished. First cost and cost of operating are not the sole considerations in any apparatus; in addition to the cost the collateral advantages derived from its use must be considered.

In domestic work there are large numbers of chafing dishes, small tea kettles, sad-irons, etc., in use. Once used the value of this method of heating is well appreciated, and extensions of it are made to more and different work. In this slow, conservative way, electric heating in households is progressing, and there are indications of a more and more rapid general reception and use.

There are some installations in which all or nearly all the cooking is done by electricity. These are generally successful and economical, according to the extent to which extensive water heating is eliminated. Laundry and pressing irons are found almost uniformly satisfactory. So with all devices used in the dining room, as, for example, chafing dishes and small tea kettles. When it comes to the kitchen the same feeling of cleanliness and elegance as for the dining room is expressed and hoped for, but the housewife is not so intimately in contact with the apparatus, and we encounter ignorant manipulation which, however, generally does no other harm than to add to the expense of running. But fortunately the manipulation and control of the apparatus is so simple and saves the servant so much hard work that an honest effort is usually evident to use it economically.

In industrial work the progress of electric heating is more rapid than in domestic applications. There are cases where heating by electricity is found cheaper than by fuels, setting aside all collateral advantages. In electric cars the equable distribution of heat on a basis of effective warming is sufficient, in the judgment of shrewd business men, to warrant employing the method and apparatus, even at considerably greater cost than former methods of heating.

We have before us for the future two methods for the distribution of heat; the first a multi-potential heat system in which steam and electricity are the means of transmission, and, second, a constant potential heat system in which electricity is employed as agent for diffused heat work in large volume, and the heat of resistance, either directly or with the additional heat of combustion of carbon, is used for high temperature purposes. The first is a combination of well-known engineering practices and represents elements in successful use at the present time. The second method appears more difficult, as it includes new methods of application and untried apparatus. For the present we have to approximate the probable final conditions by using materials at hand, so far as they will go, with reasonable economy, using every energy to broaden the general conception of the help and convenience arising from central station heat supply.

1. Car Heating.—The electric car heater has a small coal stove as its chief competitor. The car stove is usually placed midway in the car, the seat on one side having been cut away to let it fit in snugly, taking thereby the seats of two passengers. This system of heating is manifestly a poor one considered on the basis of heat distribution, and it also aggravates the faulty ventilation of a street car by gases from the coal burned.

In house or space heating on a considerable scale the generator can be located at a convenient point and the heat energy distributed efficiently by hot water or steam. In electric street cars the space to be heated is so small as to practically preclude the economical use of this method of heating. Hot water storage systems have been suggested and tried; but the objections of charging, attendance, etc., are evident.

The electric railway company usually owns its own generating plant, which has been erected specially for the purpose with good boilers, efficient engines, and large unit generators. The cost of power is a minimum, and there are cases in which it is figured to cost not over $2 per horse power per month. It is in a measure the ability to generate the power cheaply that makes it profitable to operate street railways by electricity. This same reason makes a certain amount of energy available for effective car warming at reasonable cost. The amount of energy available is dependent upon local conditions peculiar to each road.

Most of the car heaters now used are air heaters; that is, the resistance is so arranged as to permit the air to impinge directly against it and carry away the heat by convection currents. The heat ascends to the monitor and is rapidly diffused with the cold air sifting in through openings in ventilators and window frames.

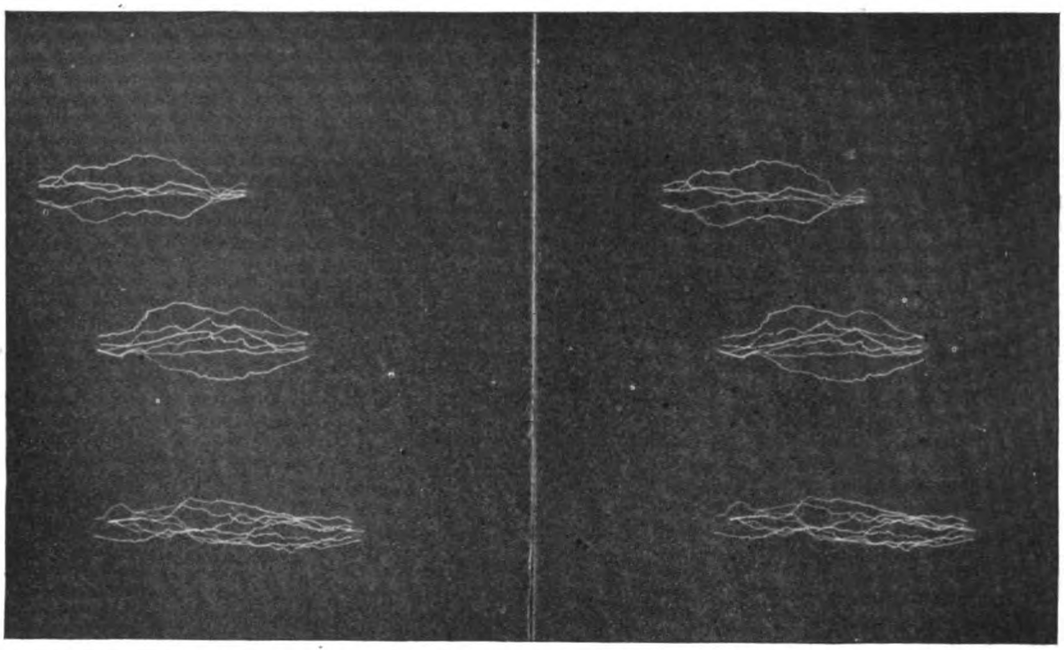
It may well be questioned in the light of modern heating practice whether this form of heater is best adapted for the peculiar conditions in car heating work, which really should be not heating at all, but effective warming. In common house heating, where electric heaters are used to give results immediately, they are connected in circuit; this is a better way to make the heater than a radiating surface. But in car work, where the heater is practically continuously in circuit, the radiator forms a better means of keeping a large percentage of the heat delivered at or near the floor of the car and about the bodies of the passengers.

1 Abstract of paper read before the Am. Society of Heating and Ventilation.

ELECTRICAL DISCHARGES INVESTIGATED BY MEANS OF STEREOSCOPIC PHOTOGRAPHY.[1]

By Professor Charles F. Himes, Ph.D,

In a previous article urging the introduction into the market of a stereoscope with simple adjustments adapting it more completely to comfortable and effective use, and a greater range of applications, attention was incidentally called to some of the peculiar possibilities of stereoscopic investigation of space phenomena, aided by photography. The accompanying stereograph may serve as an illustration of a permanent record of a phenomenon in space, so evanescent as to elude direct observation. The subject is a succession of sparks between the poles of a Holtz machine. The pictures seem identical, even upon close inspection. There seems to be nothing in these lines, representing the paths of the several sparks, to indicate with any certainty their relative positions in space. As far as either single picture gives any information they form simply a bundle of very irregular and very confused lines. They might all be in the plane of the paper, or any one of them can be regarded as lying in front of, or behind the plane of the paper, at will. But when the pictures, viewed as a stereograph, are binocularly combined by aid of the stereoscope, or otherwise, they immediately assert their character as right and left eye pictures. The confused mass resolves itself into distinct and separate lines, each with its peculiar shape and its true position in space. As the sparks were taken not simultaneously but in succession, with any desirable interval of time between, it is plain that each one has impressed upon it, the effect of any conditions peculiar to it, and that by varying conditions under which the sparks may be produced, in turn, the effect of any one upon the shape, position and general character of the spark can be studied. Appearances that in a single photograph might be assumed to be due to difference in distance, might require some other explanation when the binocular pictures negative that assumption.



Electrical Discharges Investigated by Stereoscopic Photography.

The poles in this case were five inches apart, with small condensers attached. The camera was an ordinary stereoscopic camera with the usual separation of the lenses. It was focused upon a card held between the poles, and the lenses were uncapped, in a darkened room of course, and the machine turned until the desired number of sparks had passed. The camera was then elevated, and a second and third series of sparks obtained on the same plate. At times branches of such extreme delicacy are obtained that they cannot be rendered by a process block. Bromide plates from the most rapid to the slowest process plates, non-halation and orthochromatic, and even wet collodion plates all gave excellent results.

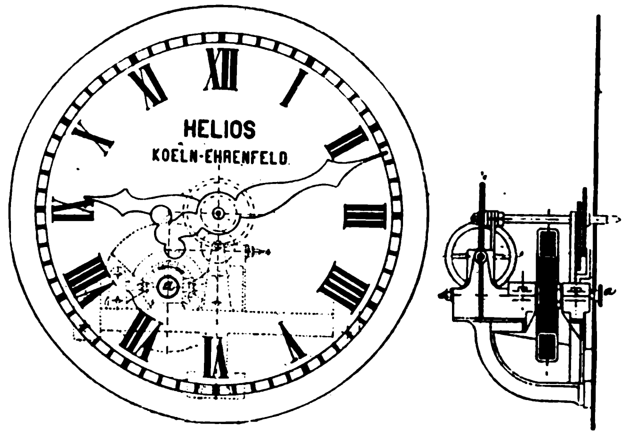
The ordinary stereoscope may be used for viewing the accompanying stereograph; but an ordinary steel-framed pair of spectacles, with lenses of about six inches focus, can be adapted to the purpose by widening the distance between the lenses, by cutting the bridge so that the eyes may look through the edges instead of the centers of the lenses. Such spectacles will be found more convenient in many cases than the ordinary instrument. Of course, those accustomed to combine the pictures of a stereograph without any instrumental aid will have no difficulty in this case.

The separation of the pictures in the accompanying illustrative stereograph has been made greater than normal in reproducing, and may, therefore, occasion difficulty for some. In such cases it may be considered as illustrating more than was intended, namely, the desirability of an adjustable stereoscope.

[1]"Photographic Times," February, 1896.

ALTERNATING CURRENT CLOCKS IN COLOGNE.

For some time past the Coerper system of alternating current clocks has been in operation on the circuits of the municipal plant in Cologne, Germany. These clocks consist of an alternating current motor, illustrated in Figs. 1 and 2. The armature of these motors is an unwound iron star which drives the hands by a suitable clock train. The clock must evidently indicate correct time as long as a master alternating clock at the central station corresponds with a pendulum clock also at the station. If the master clock shows a small variation from the normal time, it is easily corrected by the engineer, who changes the number of alternations of the current slightly, and thus influences the synchronous clock motors correspondingly. This regulation is extremely simple. The clocks show but a very small daily variation and thus constitute the most sensitive tachometers, and at the same time prove the close regulation of the machines.



Helios Alternating Current Clock.

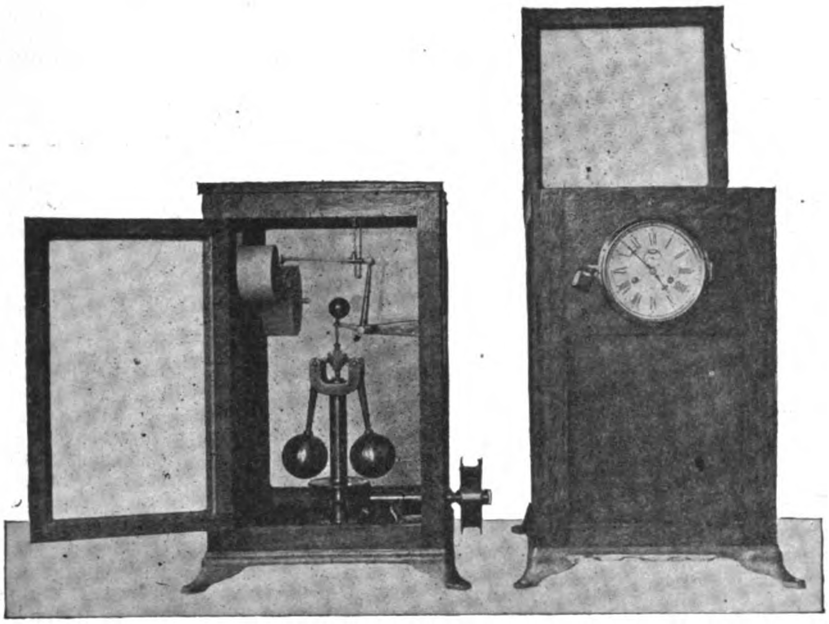
The current consumed by each clock is about 7 watts. The clock is started by means of the milled nut A, which is connected directly to the star-shaped armature.

THE NEW LOMBARD SPEED RECORDER.

THERE is no one thing about an electric station which is of more importance than to know when machinery starts, when it stops, and what its exact speed was at every moment when it was running. An exact knowledge of the above facts answers many perplexing questions in the engineering department, and also enables the manager to talk with perfect confidence to irritable customers who relate exaggerated accounts of faulty light or power service due to "shut downs" or variable speed

To meet the above want the Lombard Water Wheel Governor Company, of No. 61 Hampshire street, Boston, Mass., has placed on the market a speed recorder, which is shown in the accompanying cut. This instrument illustrated in Fig. 1 leaves little to be desired in the way of sensitiveness, accuracy, and reliability. It is strongly built, beautifully finished and is reasonable in price. A photographic reproduction of the paper strip used with this instrument is shown in Fig. 2. It will be seen that the speed, corresponding to each longitudinal line, is printed on the paper so that there can be no mistake in reading the speed correctly; these figures are printed at six-inch intervals. At the upper edge of the paper strip numbers from 10 to 60 are printed. These indicate minutes, and at the beginning of each hour the pencil marking the record of speed stands directly over the line marked 60. The paper is fed forward, from left to right, the distance between each vertical line, every five minutes, and by writing the hour on the line marked 60 the time of any speed variation during the day may be readily found. The feed motion is positive so that there is no possibility of the record on the paper strip not corresponding with the time indicated by the clock.

This instrument was not originally gotten up to sell, but was intended purely for the experimental work of the Lombard Water Wheel Governor Company, but so many persons who had seen this speed recorder at work expressed a desire to purchase one that it was decided to build them in commercial quantities. It is not often that a machine is made which will sell itself, but it is a fact that before the first lot of these speed recorders were finished they were all sold, and that without any solicitation on the part of the manufacturer. From this fact it would seem that these machines fill a popular want.



Side View with Door Open. Front View with Top Open.

FIG. 1.—THE LOMBARD SPEED RECORDER.

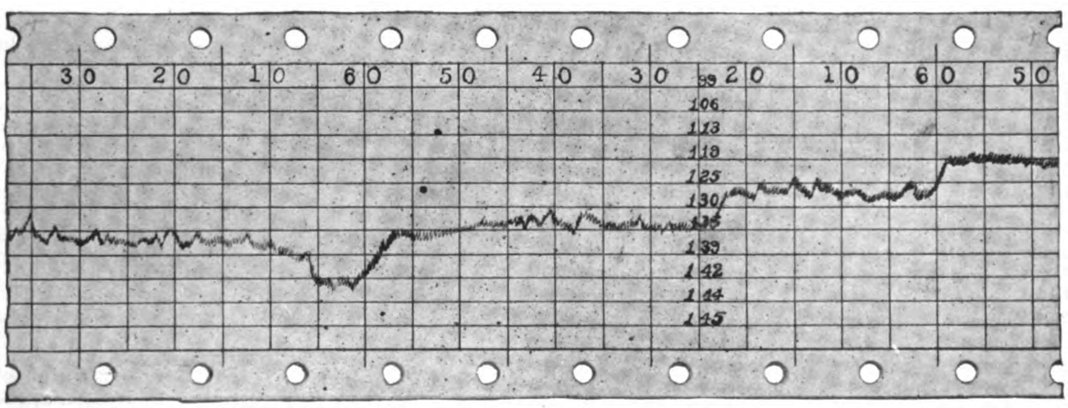


FIG. 2.—RECORD MADE BY THE LOMBARD SPEED RECORDER.

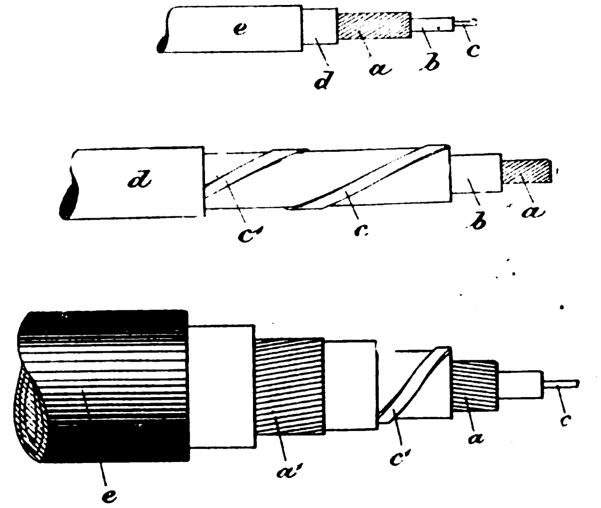
GUILLEAUME'S INSULATED WIRE CABLE.

IN the equipment of coal mines with electric light and power transmission great care is taken, in the case of gaseous mines, to avoid the generation of sparks, which might ignite the fire damp and thus cause explosion. These precautions have heretofore been confined exclusively to obtaining sparklessness at the machines in the pits, but it is evident that danger still lurks in the conductor itself, which may be ruptured, and thus create an arc. It is with the object of providing for this contingency that Mr. Theodore Guilleaume, of Mülheim-on-Rhine, Germany, has devised several types of cable which are illustrated in the accompanying engravings.

According to one mode of construction, illustrated in Fig. 1,

the cable comprises a main conductor, a, surrounding a safety-conductor, c, but separated therefrom by insulating material b; d, is another insulating-covering and e, an outer protective covering. The main conductor, a, is made of copper or other ductile metal and the safety-conductor of steel, bronze or other metal which, unlike the soft and ductile copper, will bear comparatively little elongation without breaking. In the event of the cable being subjected to excessive tensile strain the independent current traversing the safety-conductor, c, is first interrupted in consequence of that conductor breaking, the effect being that the main current is diverted from the principal conductor, a, before the latter breaks.

Where there is reason to apprehend crushing, the cable is



FIGS. 1, 2 AND 3.—THE GUILLEAUME SAFETY MINE CABLE.

constructed as illustrated in Fig. 2. In this instance the safety-conductor, c c', in the form of a bipart steel tape, is wound round the insulated copper conductor, a, in a coarse-pitch double spiral. Where such a cable is liable to damage from concussion or crushing only (as distinguished from excessive tension) the main and safety conductors are, respectively, made of metal of equal ductility; but when it is desired to provide in addition against the effect of tension the safety-conductor is composed of metal having less ductility than that possessed by the main conductor.

The above described arrangement may be adopted in connection with cables composed of several conductors, in which

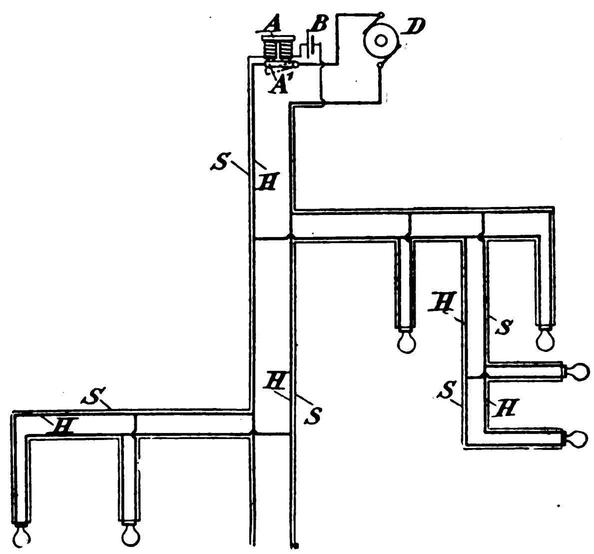


FIG. 4.—THE GUILLEAUME SAFETY MINE CABLE.

case the cable must be provided with at least two safety-conductors. These latter may assume the form of a pair of conductors in the center of the cable, as shown in Fig. 1, or as indicated in Fig. 3, but the most advantageous arrangement of the safety-conductors is shown in Fig. 4, where one of the safety-conductors, c, is in the center of the cable, while the other, c', in the form of a metallic tape, occupies a position either between the inner main conductor, a, and the outer main conductor, a'.

The method of connecting a cable such as described with reference to Fig. 1 is illustrated in Fig. 3, D representing the dynamo supplying current to the main circuit, H, B the battery supplying current to the safety-circuit S, and A A' the switch device adapted, on the interruption of the safety-circuit, to intercept communication through the main conductor.

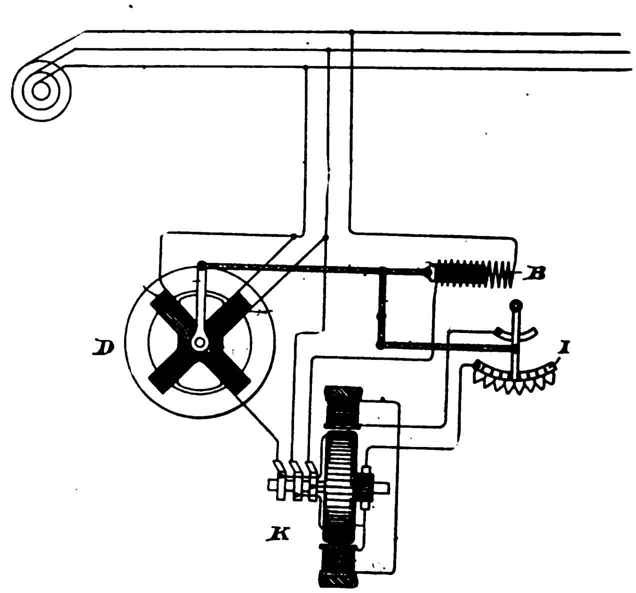
Throughout the line all the safety wires, c, Fig. 1, are included in one circuit, S, to which current is constantly supplied by the battery, B, this current being just strong enough to retain the armature A of the switch or "cut-out" in position for enabling the other or more powerful current to traverse the main circuit H. When the safety-current is interrupted the armature, A' being no longer attracted, falls away and instantly effects the interception of the main circuit H. Thus, when a cable, forming the main electric line, is strained to a point threatening it with rupture the safety-wire c, being less ductile than the main conductor a, breaks, interruption in the main circuit H ensuing before the copper conductor a itself breaks.

BERG'S METHOD OF REGULATING THE PHASE OF ALTERNATING CURRENTS.

IT is well known that the most efficient operation under ordinary circumstances is obtained for alternating-current systems of distribution when the current and electromotive force in the circuit are in phase. Mr. Ernst J. Berg, one of the engineers of the General Electric Company, has devised an arrangement of apparatus which will respond to a difference of phase between the current and electromotive force, and by such response will tend to correct the distortion of phase between the two power elements in the circuit.

Mr. Berg employs a synchronous motor, K, connected between the lines of the system of distribution. To control the excitation of this motor an ordinary resistance, I, is used, and to control the amount of resistance in circuit with the field the rheostat is connected to a solenoid, B, influenced by the amount of current passing to the synchronous motor.

Opposing this current device is a watt mechanism, D, so that when the current is in phase with the electromotive force



BERG'S METHOD OF PHASE REGULATION.

the power exerted by the watt mechanism is balanced by that of the current-actuated device, and the resistance will not be changed. When, however, the current lags, it becomes larger, and therefore the current-actuated mechanism, B, acts with more force than the watt mechanism, which depends upon the relation between the current and electromotive force for its energy. The amount of resistance is then changed, the excitation of the synchronous motor is altered, and its effect upon the lines between which it is coupled is so varied as to restore the phase relation of the current.

EDUCATIONAL.

UNIVERSITY OF NEBRASKA.

The new Chancellor of the University of Nebraska, Dr. G. E. MacLean, was inducted into office on Feb. 14, at the University, Lincoln, Neb. The ceremonies were attended by large numbers of people from all over the state, from the Governor down, and from many parts of the Union. A special feature of interest to electricians was the large share in the various proceedings assigned to the electrical engineering students at the University, under the direction of Professor R. B. Owens, who has that department in charge. On the evening of Feb. 13, Mr. T. C. Martin lectured before the University and visitors on the "Development of Power at Niagara Falls." After the inauguration, a fine exhibit was given in the gymnasium of the latest things in electricity, including calcium carbide, cathodographs, cooking, heating, welding, etc., and the attendance was enormous, thousands of people inspecting the admirable display as well as the engineering buildings, and equipment. On the tower of the main University Building, the electricals erected a large Franklin kite, framed in lamps, from the base of which a long tail, also made up of lamps, was strung across the campus to a pole. By means of a commutator, current was continually flashed over the kite and up and down the tail, with most brilliant and startling effect. It is needless to say that the electricals covered themselves with glory. Although the new Chancellor, Dr. MacLean, is not closely associated with physical or engineering pursuits, his previous post having been that of Professor of English Literature at the University of Minnesota, his profoundly able inaugural address showed him to have deep sympathy with such studies, and the prominence allowed to electricity upon so important an occasion is fitly regarded not only as a great compliment, but an earnest of liberal support and encouragement for electrical engineering at the hands of the governing body.

"HOME STUDY."

In connection with their courses of work in the International Correspondence Schools, the Colliery Engineer Company of Scranton, Pa., are now publishing an admirable periodical manual or text book which they call "Home Study." It is full of excellent data for the use and benefit of those who are employing their leisure in study of mathematics, engineering, physics, etc., and cannot but be extremely helpful to all who engage in the praiseworthy effort of self-improvement. The paper is neatly and handsomely printed, and is a credit to the publishers.

SOCIETY AND CLUB NOTES.

A BROOKLYN SOCIETY OF ELECTRICIANS.

We learn that a movement is being actively pushed in Brooklyn to establish a local society of electricians, whose chief objects will be to draw together practical men and to open a place of meeting equipped with books, apparatus, etc., It is proposed to divide the membership into two classes, associate and active. The latter will comprise those who possess a thorough knowledge of the science; the former class will include those generally identified with electrical and kindred work. The divisions will be strictly adhered to. The initial meeting will be held at 17 Whipple street, Brooklyn, on Feb. 28, at 8 P. M., to adopt a constitution and elect officers. We are informed that many men are already enrolled, all the Brooklyn central stations being represented in the list of membership.

HENRY ELECTRICAL CLUB.

At a meeting of the Henry Electrical Club, held on Feb. 14, Mr. H. T. Wade, of Columbia College, lectured on "Measurement of Resistance." Considering the subject under the divisions of high, medium, and low resistances, Mr. Wade described various means employed in taking measurements, and explained the conditions met in dealing with each class. Describing the Wheatstone Bridge, he entered very fully into its theory, and gave formulas showing the best proportions of its parts under given conditions. The determination of specific resistances of metals, with the precautions taken to eliminate errors, were clearly explained. In the measurement of insulation the lecturer fully described the method of direct deflection, with the manner of taking a constant; and he pointed out the disturbing factors in cable testing.

Mr. Wade's lecture, while comprehensive in its treatment of the subject, was noteworthy in its avoidance of description of any but the most modern and approved practice.

AMERICAN INSTITUTE OF ELECTRICAL ENGIEEERS.

The nomination blanks for the ticket of the American Institute of Electrical Engineers have been issued, and are now in the hands of the members. A number of the friends of Professor F. B. Crocker, of Columbia College, are filling in his name, for the presidency. It would certainly be difficult to make a better choice. Professor Crocker has already served the institute in various capacities and has done a large amount of hard work, particularly on the committees of editing and papers. The honor will be well bestowed, should he be elected.

The 103d meeting of the Institute will be held at 12 West 31st street, on Wednesday, Feb. 26, 1896, at 8 o'clock P. M. As already announced by a notice framed by the Committee on Incorporation to comply with the laws of the State, the first business of the meeting will be the consideration of a proposition to incorporate the Institute. The discussion of the paper by Mr. Frank J. Sprague on "Electric Elevators, Their Uses and Advantages," will be taken up in accordance with the action at the last meeting. The postponed discussion will be reopened by Dr. Cary T. Hutchinson.

NEW YORK ELECTRICAL SOCIETY.

On the invitation of the Edison Electric Illuminating Company, of New York, the next meeting of the society will be held at their station, 57 Duane street, on Thursday, Feb. 27, at 8 P. M. On this occasion Mr. John W. Lieb, Jr., the president of the society, will deliver an address on "The Generation and Distribution of Current by an Edison Station." By the courtesy of the company the station will be thrown open for the inspection of the visitors. Members are requested to notify the secretary of the society, at 203 Broadway, not later than Wednesday, the 26th inst., of their intention to be present, in order that proper arrangements for their reception may be made.

REPORTS OF COMPANIES.

THE WAGNER ELECTRIC MANUFACTURING COMPANY.

The Wagner Electric Manufacturing Company, of St. Louis, Mo., has been incorporated since August, 1891, and since that time its business has increased from $10,000 to a business of $200,000 a year. This progress is regarded as not only due to the exhaustive work of the managing department, but to the very superior line of articles manufactured. All articles that were placed on the market within this period have been considered to be of the very best in their respective lines, and standard from the point of efficiency and durability.

In August, 1893, the company was compelled to move to its present quarters, at 2017 and 2023 Olive street, from its old factory at 1822 Olive street. It then had a capital of $25,000. The daily improvement of business demanded its increase, which was duly made to $100,000. Since then to the present time it has gradually increased to the present maximum in sales, of $200,000 annually, and finds its quarters entirely inadequate for their purposes. In December last it was found important to enlarge the manufacturing facilities in order to take care of the demand for its specialties. The three-story factory, which it owns and now occupies, covers a ground space of 45x70 feet. In front of this building the company proposes to erect a building which will cover a lot 125x70 feet. The building will be seven stories high when finished.

For the purpose of this work it was necessary to increase capital stock. At a meeting of the stockholders, held on the 17th inst., it was unanimously voted to increase the capital stock from $100,000 to $250,000, and at the Board of Directors meeting, held on the 18th, it was decided to begin the erection of the new building at once on the plans submitted for approval. The additional floor space will permit of tripling the present output, and the company will then begin to manufacture more extensively its recognized high grade specialties, for which in a short time it will be in the field soliciting orders.

Of late the company has been working overtime, and in fact two shifts during part of the winter, but even then was compelled to turn down some orders which it could not handle on account of the brief time set for their shipment. It is in a better position now to fill orders, as the buying has moderated considerably, and, in fact, can fill orders for motors, transformers, generators, etc., within a reasonable time from their receipt. The general outlook remains excellent.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED FEB. 18, 1896.

Alarms and Signals:—

ELECTRICALLY OPERATED RAILWAY TRACK SWITCH. F. H. Harriman, Hartford, Conn., 554,868. Filed Dec. 11, 1895.
Means for electrically operating a track switch with current from the line wire.

MANUALLY CONTROLLED ELECTRIC BLOCK SIGNAL SYSTEM. A. G. Leonard, New York, 554,884. Filed July 26, 1894.
Comprises a rocking spindle, a plunger, a circuit closer and a swinging bar or plate under the control of the rocking spindle to prevent or permit the action of the plunger.

FIRE ALARM TELEGRAPH SYSTEM. J. F. Mehren, Chicago, Ill., 554,889. Filed April 4, 1894.
A system having two main lines over each of which every signal is transmitted.

ELECTRIC CIRCUIT CLOSER AND BREAKER. J. R. Farmer, St. Louis, Mo., 554,918. Filed May 25, 1894.
A means for closing and breaking the electric circuit used in connection with electric signal lamps.

SAFETY SYSTEM FOR RAILROADS. B. C. Rowell, Boston, Mass., 554,957. Filed Sept. 4, 1894.
The combination of an automatic electrical locking device locked by the presence of a train on any section and locking the locking bar which controls the bolts of the locking apparatuses.

Conductors, Conduits and Insulators:—

INSULATOR. E. Peloubet, Alexander, Ark., 554,723. Filed Nov. 1, 1895.
A base of metal with openings therethrough, one of which has a communicating slot and glass insulators in said openings.

INSULATOR FOR ELECTRIC WIRES. M. Riera, Havana, Cuba, 554,955. Filed Sept. 5, 1895.
Incloses two clamp members so as to inclose between them a substantially prismatical space and an elastic filling held in said space and apertured for the reception of the wire.

Dynamos and Motors:—

INDUCTION MACHINE. W. K. Freeman, Fort Wayne, Ind., 554,670. Filed July 5, 1895.
A dynamo involving a compact structure, in which a magnetic circuit is secured with a minimum air-gap between the field and armature core.

Electrolysis.—

PROCESS FOR PRODUCING LAKES OF COLORING COMPOUNDS BY ELECTROLYSIS. R. McKenzie, Jersey City, N. J., 554,718. Filed Feb. 21, 1895.

Electrometallurgy:—

ORE-CONCENTRATOR. J. O. Dimmick and E. K. Woods, Denver, Colo., 554,914. Filed April 27, 1895.
Means for arresting and separating the metallic portion of pulp as the same, in a granulated or pulverized form, is forced by means of water over the concentrator bed.

Lamps and Appurtenances:—

KEY SOCKET FOR INCANDESCENT LAMPS. B. W. Snow, Syracuse, N. Y., 554,896. Filed Jan. 2, 1895.
Details of construction involving an insulated base.

Lighting System:—

LIGHTING CARS. W. F. Hutchinson, New York, 554,697. Filed April 15, 1895.
The combination with the car and the revoluble screw on the car track, of the generator on the car, and a train of gearing connecting the generator with the screw.

ELECTRIC LIGHTING SYSTEM. E. L. Slocum, Pawtucket, R. I., 555,057. Filed April 3, 1893.
Consists in the employment of an automatically operated mechanism provided with a plurality of electric contact points for closing and breaking the electric circuit, so as to cut successive batteries in and out.

Miscellaneous:—

GAS LIGHTING SAFETY APPLIANCE. F. and F. H. Engelhard, Springfield, Mass., 554,665. Filed June 3, 1895.
A source of electrical energy, a series of conductors, a gas burner, an induction coil and a make-and-break mechanism governed by clock mechanism.

HEAT REGULATOR. E. Frischnecht, New York, 664,671. Filed March 9, 1895.
Consists substantially of a thermometer, an electric motor operating a heat regulator, an electric circuit, extending from the thermometer to the motor, and an adjustable contact included in said circuit.

LAUNDERING APPARATUS. D. Reynolds, Evansville, Ind., 554,795. Filed Dec. 15, 1894.
The water is subjected to electrolysis.

ELECTROMAGNET. J. Houlehan, Chicago, Ill., 554,821. Filed May 10, 1895.
Provides a construction of electromagnet whereby dead centers on the pole pieces shall be prevented.

MEANS FOR RECORDING AND REPRODUCING IMPULSES. W. H. Cooley, Brockport, N. Y., 554,862. Filed April 16, 1889.
A recording surface and means for producing undulations in an electric current caused to pass therethrough.

ELECTRIC HEATER, RESISTANCE, OR RHEOSTAT. P. B. Delaney, South Orange, N. J., 554,910. Filed June 7, 1892.
The heating or resistance conductor is strung through buttons of fireproof insulating material.

Primary Batteries:—

ELECTRIC BATTERY. C. Willms, Baltimore, Md., 554,759. Filed May 3, 1893.
Consists of a number of small dry cells, which may readily be placed in and removed from their support in the battery.

ELECTRIC BATTERY. C. Willms, Baltimore, Md., 554,760. Filed Jan. 19, 1894.
Details of construction of a chloride of silver cell.

ELECTRIC BATTERY AND METHOD OF SEALING BATTERY CELLS. C. Willms, Baltimore, Md., 554,761. Filed July 12, 1894.
Relates to a chloride of silver cell.

GALVANIC BATTERY. E. L. Slocum, Pawtucket, R. I., 555,056. Filed July 2, 1894.
A means for automatically amalgamating the positive electrode.

GALVANIC BATTERY. E. L. Slocum, Pawtucket, R. I., 555,058. Filed March 28, 1893.
Combination with the carbon electrode and the zinc electrode, of an insulator surrounding the zinc electrode on all sides within the exciting fluid.

Railways and Appliances:—

TROLLEY SUPPORT. F. E. Homer, Cleveland, Ohio, 554,694. Filed Nov. 30, 1894.
Spring tension suspended trolley pole support, in which the degree of the tension will remain nearly uniform.

CONDUIT ELECTRIC RAILWAY. W. Osterlein, Cincinnati, Ohio, 554,719. Filed Sept. 21, 1894.
A metallic current conducting rail and its supports in a tunnel between the tracks of the railway and a traveling contact device for taking the current through the motor upon the car.

RAIL BOND FOR ELECTRIC RAILWAYS. R. C. Brown, Somerville, Mass., 554,859. Filed March 21, 1894.
Comprises a hollow plug inserted through each of the rails, and a tie-wire extended through said plugs.

RAIL BOND FOR ELECTRIC RAILWAYS. S. Nikoloff, Worcester, Mass., 554,949. Filed Jan. 2, 1896.
Comprises an outer cylinder joined at one end with an inner cylinder axially concentric and parallel therewith, and having an annular intervening space for the reception of a tubular key or expander.

ELECTROMAGNETIC INDUCTION SYSTEM OF PROPULSION. A. C. Shuttleworth, Philadelphia, Pa., 554,962. Filed Feb. 7, 1895.
Employs an alternating or interrupted current traversing a stationary primary conductor in inductive proximity to a moving secondary conductor, and also stationary parts of a magnetic circuit and moving parts of a magnetic circuit.

Telephones:—

TELEPHONY. F. R. Colvin, New York, 554,656. Filed Nov. 24, 1894.
Provides a system of intercommunication for a plurality of subscribers, by which the advantages of a round metallic circuit with a minimum amount of self-induction may be afforded.

ELECTRICAL CONNECTING CORD. C. H. McEvoy, Lowell, Mass., 554,716. Filed May 15, 1895.
Comprises two covered conductors, inclosed in a common covering and projecting from the ends thereof, and one or more suspension cords, arranged in said covering.

TELEPHONE. W. H. Russell, New City, N. Y., and G. E. Russell, Little Falls, N. Y., 554,895. Filed Aug. 10, 1895.
Combines in one the instrumentalities of a carbon transmitter and a magnetic receiver.

PERSONAL.

MR. HARVEY MIDDLETON, manager Pullman Car Works, having tendered his resignation, the same has been accepted. Until further notice the present assistant managers, A. M. Parent and Frederick Wild, will have immediate charge of the Pullman Car Works, and will report to the general manager direct.

MR. LUDWIG GUTMANN has accepted the position of electrical engineer with the Royal Electric Company, of Peoria, Illinois.

MR. WALTER C. M'KINLOCK, Secretary of the Metropolitan Electric Company, has the sincere sympathy of all of the electrical fraternity at the death of his baby boy last Saturday.

MR. DINSHAH PESTONJEE GHADIALLY is a recent visitor to this country from India, where he held until recently the position of electrician to the Maharajah Rana Sahib of Dholpur, a native principality between Agra and Gwalior. Mr. Ghadially is on a trip around the world inspecting for his own information all the various electrical plants along his route.

MR. S. G. BOOKER, superintendent of the Phœnix Carbon Manufacturing Company, St. Louis, Mo., was a visitor to Chicago last week.

MR. C. H. WILMERDING, president of the National Electric Light Association, was in New York last week in active consultation with Mr. Porter, secretary of that body, and the officials of the exposition. He found the outlook for a large meeting and a fine exposition of the most brilliant and encouraging nature.

LEGAL NOTES.

A PRIORITY CLAIM ON LIGHTING BUOYS.

Wm. R. Wood, of Scotland Neck, ex-superintendent of the Insane Asylum at Raleigh, N. C., has brought suit to recover half a million dollars damages from the United States Government for infringement upon his patent for electrically lighting buoys. He obtained a patent in 1876, and in 1888 the Government suddenly adopted his system. The case comes up in the Court of Claims this spring.

ELECTRICITY FOR NEW YORK CANALS.

Senator Lamy has introduced a bill in the New York Senate authorizing Superintendent Aldridge, of the Public Works Department, to expend $500,000 for the equipment of the canals of the state with electrical motive power.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

POETRY AND PAINTS.

With the coming of each and every spring, editors and publishers are offered "Spring Poetry," which is considered by the authors, of a quality quite equal, if not superior, to anything ever launched upon the poetry-loving world. As with poetry, so it is with paint—as the spring season of painting and repainting comes along there is sure to be offered something new in the way of paint mixture for the protection of roofs, iron work, etc. Fortunately the public, as a rule, discriminates as wisely against such new nostrums as it does in its poetry, and rightly chooses a paint like Dixon's Silica Graphite Paint, which has been so favorably known for over a quarter of a century.

Roofs painted with Dixon's "Silica Graphite" Paint have not required repainting in twelve to fifteen years and over. Railway and other corporations known for their thorough testing and careful selection of materials, use this paint in large quantities.

Any one desiring to know more about Graphite Paint should address the Joseph Dixon Crucible Company, Jersey City, N. J.

THE STANDARD WATER TUBE SAFTY BOILER.

The Standard Boiler Company, 1120 and 1121 Marquette Building, Chicago, Ill., claim that the superiority of their boiler over the ordinary type lies in its economy in the use of fuel, its freedom from possible explosion, its perfectly free and unrestricted circulation, and the ease with which any part may be examined for cleaning and repairs. The purifying chamber is a peculiar feature of the boiler, which has been designed for the exigencies of the Western trade. The large quantities of impurities in the water throughout the Middle and Western states necessitates the use of a means of purification at once simple and effective. This is exactly what the purifying chamber affords, they say. It gives the benefit of a live steam feed water purifier at a slight additional cost, and reduces the scale formation in the boiler to a minimum, keeping the tubes and the whole interior clean, and consequently increasing the efficiency of the heating surfaces, as well as the saving of fuel.

M'INTOSH, SEYMOUR & CO.'S RECENT WORK.

Among the recent orders received by Messrs. McIntosh, Seymour & Co. is one from the Columbian and Maryland Railway Company to build them eight engines of 1,000 horsepower each, that will couple direct to 700 kilowatt Westinghouse generators.

They are also making two 1,200 horsepower, 800 kilowatt, direct coupled engines for the City and Suburban Railway Company of Baltimore, Md., making six sold that company. Other orders include two 1,200 horsepower, 800 kilowatt direct coupled engines for the Cincinnati Street Railway Company, making fourteen sold that company; two 1,200 horsepower engines for the Municipal Electric Light Company, of Brooklyn, N. Y., and one 1,000 horsepower cross-compound vertical engine for the Atlantic Mills of Lawrence, Mass. The above are sales for slow-speed engines since Jan. 1, 1896.

McIntosh, Seymour & Co. are also making a 700 horsepower, three-cylinder, three-crank vertical engine, direct connected to two 200 kilowatt dynamos, for Buenos Ayres, Argentine Republic.

In addition they are busy on a lot of orders for their regular high-speed engines.

THE UNITED STATES TELEPHONE CONSTRUCTION CO.

The United States Telephone Construction Company, of Philadelphia, have moved their offices from the Bullitt Building to very handsome quarters in the Philadelphia Bourse. They have also largely increased their capital and are going into the telephone business on a much larger scale than heretofore, their plan being to organize state or subcompanies to cover the entire United States, and allow these companies to manufacture their own instruments when desired, thus giving each subcompany all the manufacturing profit and an opportunity to meet all local requirements. The management assert that if the Berliner patent is sustained by the United States Supreme Court, this company, "owning and controlling the method patent for a make and break telephone, will be practically the only opposition the Bell Company will have." They will make five styles of telephones and guarantee each and every one of them to be absolutely non-infringing in every particular. Their new long-distance 'phone is guaranteed to talk over 5,000 miles of resistance.

THE WASHINGTON ELECTRIC CO.

The Washington Electric Company, of Chicago, have removed from their old quarters at 205 and 207 South Canal street to the new Russell Building, 31-45 W. Randolph street. The business of this company has had such a rapid increase during the past few months that the facilities for manufacturing in the building which they have just vacated were utterly inadequate to permit them to execute their orders on time, and the change has been in every sense a most desirable one. The space which this concern have secured is at least twice as large as they had before, and comprised a large factory and fine general office; also a private office for the use of Mr. W. A. Meissner, the president and manager of the company. The factory is equipped with the newest and most improved machinery necessary for the manufacture of the electrical goods which they turn out. It is very lofty, has a southern aspect, and a very large window space which gives fine light throughout the entire place.

BERLIN IRON BRIDGE COMPANY.

The Berlin Iron Bridge Company, of East Berlin, Conn., have a contract for a steel floor to be placed in one of the buildings of the Alexander Smith & Son's Carpet Factory, at Yonkers, N. Y. They also have a contract for furnishing the ironwork for Meara Bros.' new block at Torrington, Conn. This block is three stories high and the girders are placed in the ceiling of the first floor and made sufficiently strong to support the two upper floors. The top floor is a dancing hall and the structure has been made with the view of making the building as stable as possible, and avoid any danger of vibration caused from the use of the dancing hall on the upper floor.

STANDARD PAINT AGENCY FOR "SHIP" CARBONS.

The Standard Paint Company, No. 2 Liberty street, New York, the well-known manufacturers of the better known P. & B. goods, have accepted the agency for the United States and Canada of the celebrated "Ship" Carbons, manufactured in Vienna by Messrs. Schiff, Jordan & Co. Electricians are already familiar with these well-known carbons, they having been handled here for some little time by Mr. Frank S. De Ronde. While the business will be continued by the Standard Paint Company, Mr. De Ronde will give it his special attention, and look after the same as heretofore. The company have arranged to carry a very large stock of these goods in New York at all times so as to be prepared to make prompt shipments. The carbons are claimed to be of the very highest order, and give a steady, brilliant light at a minimum current without dust, noise or hissing. The importers will willingly send samples gratis on application. It will pay all those interested to at once correspond with the Standard Paint Company, who up to April 15 will be at the old stand, No. 2 Liberty street. After that date they will occupy their new and larger quarters at 79 and 81 John street, necessitated by the steady and growing demand for the P. & B. products.

FLUORESCING SALTS FOR ROENTGEN X-RAY EXPERIMENTS.

The universal interest displayed by physicists in Röntgen's recent discovery has developed an unprecedented demand for the salts of platinum, which fluoresce under the impact of the X-rays. Messrs. Baker & Co., the Platinum refiners, of Newark, N. J., inform us that they have sold more of the particular salt recommended by Röntgen as most suitable for X-ray experiments, namely, Barium Platino Cyanide, than ever before in the history of their business, and that in consequence of the undiminished demand for this salt they have been obliged to increase their laboratory force.

THE ELECTRIC APPLIANCE COMPANY have been pleasantly surprised at the way in which their wire sales have held up since the first of the year. It is usual to look for quite a falling off in this material after Jan. 1, but the demand for both "O. K." Weather-proof wire and Paranite Rubber-Covered wire has been exceptionally good, much to the satisfaction of both the manufacturers and the Appliance Company.

THE CUTTER CO. OF PHILADELPHIA.

The Cutter Electrical and Manufacturing Company takes pleasure in announcing that the assignment made in August last has been dissolved, and that with largely increased capital, it will continue its business, as heretofore. The company will devote special attention to the manufacture of its C. S. flush switches and the I. T. E. automatic magnetic circuit breakers. The demand for "Circuit Breakers" is already taxing the present capacity of its factory.

GREEN'S ASBESTOS INSULATING PAPER.

The constant increase in the potentials employed in practice in electrical distribution makes the question of the proper insulation of armatures more and more important. Asbestos has long been recognized as of value on account of its insulating, and especially on account of its fireproof qualities, when the material employed was pure. But the difficulty heretofore has been to secure the necessary purity and the making up of the asbestos in shape suitable for general application to armature insulation. A product combining both of these essential features is the asbestos paper now being placed on the market by the Asbestos Insulation Company, of Baltimore. This paper, which is the invention of Mr. John F. Green, the president of the company, is prepared by first subjecting the asbestos fiber to a chemical process which extracts from it all the impurities of iron, copper, or other metallic particles. The purified fiber is then applied to a base of prepared manilla paper, resulting in a product which is eminently adapted to insulation of dynamos, converters, etc. Prepared in this way the asbestos paper has a thickness of only .009 inch, while it is hoped shortly to reduce even this to .006 inch.

Tests of this insulating paper .0085 inch thick have shown it to withstand puncture at 1,800 volts, while eight sheets, of a total thickness of .065 inch, withstood a strain of 7,600 volts. The influence which such an insulation may have on the economical construction of machines must be apparent. It goes without saying that no amount of heat to which this insulation can be subjected has any effect on its insulating property.

The company expects shortly to place on the market an insulating paper which shall be both fire and water proof. It is also contemplated to apply this asbestos paper to the insulation of wires, and experiments to that end are now under way. Messrs. Green & Seaman, of 23 S. Charles street, Baltimore, are the selling agents for the Asbestos Insulation Company.

ADVERTISERS' HINTS.

THE NATIONAL ELECTRIC EXPOSITION, to be held in this city during May, in connection with the convention of the National Electric Light Association, is now an assured success. Already the greatest interest and a desire to co-operate with the management has been manifested by manufacturers throughout the country. The first allotment of space will be made March 10.

THE WASHINGTON ELECTRIC COMPANY, of Chicago, have found their former quarters inadequate to the demands of their constantly growing business, and are now located in the Russell Building, that city.

THE CUTTER ELECTRIC AND MANUFACTURING CO. continues to advertise the "I. T. E." automatic magnetic circuit breakers, and they say their customers help them in doing so.

THE RUSHMORE DYNAMO WORKS manufacture photo-engraving lamps of from 1,000 to 40,000 candle-power and searchlights up to 100,000,000 candle power. A great many of their lights are now in use and their reliability makes them very popular.

THE HOLMES FIBER-GRAPHITE COMPANY are selling a commutator brush that deserves the attention of central station men.

TH INDIA-RUBBER AND GUTTA-PERCHA INSULATING COMPANY have something to say about X-rays and "looking into things."

THE BAECHTOLD & PARKER COMPANY are headquarters for everything in the way of electrical supplies.

THE BRISTOL COMPANY report business brisk and daily improving in the sales of their recording instruments.

THE STANDARD PAINT COMPANY are now the United States agents for Schiff, Jordan & Co.'s "Ship" cored carbons. They continue to supply the large demand for the S. & B. specialties.

THE MORRISON-SOUTHERN ELECTRIC COMPANY illustrate a flush switch they have recently placed on the market, which is simple in construction, efficient in operation, and cheap to install.

NEW YORK NOTES.

THE BARRIETT ARMATURE WINDING COMPANY has been formed by W. J. Quencer, A. B. Quencer and H. W. Thounard, with a capital stock of $10,000. Mr. Barriett has established a shop to carry on this special work in New York City.

THE DIRECT CURRENT TRANSFORMER COMPANY, of New York City, has been formed by A. D. Warren, P. B Welsh and W. A. Spellman, of New York City, and F. D. Goold and George Stanmore, of Brooklyn. The capital stock is $60,000.

THE ELECTRIC SIGN AND NOVELTY COMPANY has been formed to manufacture signs, with a capital stock of $250,000. The incorporators are E. O. McCook, of Dobbs Ferry, N. Y.; T. Orgell, of Brooklyn, and F. Beckbane, of Newark.

RUETE CONDUITS.—The Interior Conduit and Insulation Company has acquired control of the Ruete patents and system for making iron armored insulated conduit, and will introduce many improvements in its well-known specialties in that line. Mr. E. T. Greenfield resumes his connection with the Interior Conduit Company.

THE A. B. SEE MANUFACTURING COMPANY, of Brooklyn, N. Y., have purchased a lot of land about 200 feet long by 102 feet wide, on Pearl street, Brooklyn, extending from Front street to Water street, and will at once commence the erection of a six-story building. Their present quarters, which are in the immediate vicinity, are much overcrowded with work, and altogether inadequate for their rapidly growing business.

A. O. SCHOONMAKER, of 158 William street, New York, who is always ready to meet the demands of the trade, is now offering his Solid Sheet Mica Segments built up to required thickness ready for use. If our readers have any special pattern they want, he is ready to cut it.

WESTERN NOTES.

THE METROPOLITAN ELECTRIC COMPANY are putting on the market a double coil filament incandescent lamp for street car use. This lamp is found to give unusual satisfaction for this class of work, as it resists jarring, the filament will not break, and the lamp is long lived, without any appreciable blackening effect.

THE PACKARD ELECTRIC AND MANUFACTURING COMPANY, of Warren, O., has been formed, with a capital stock of $110,000.

THE TRIUMPH COMPOUND ENGINE COMPANY, of Cincinnati, has changed its name to the Triumph Electric Company, and has increased its capital stock from $75,000 to $125,000.

THE METROPOLITAN ELECTRIC COMPANY have just gotten a large stock of baby and large knife switches from Eyanson & Armprister, Philadelphia, for whom they are general Western agents.

N. I. R. wire has been specified in several large installations lately, and the Metropolitan Electric Company carry a large stock on hand and sell this wire in the West. Customers say it gives perfect satisfaction.

MR. J. H. M'GILL, who has recently been appointed Chicago manager of the Ohio Brass Company, Mansfield, O., in place of Mr. Max A. Berg, who is now at the head office and works of this company, has moved his office from 1533 the Monadnock Block, Chicago, to 1129-1130 the same building. Mr. McGill also takes care of the Chicago business of the Peru Electric Manufacturing Company, of Peru, Ind.

MR. M. B. AUSTIN, Western representative of the Safety Insulated Wire and Cable Company, New York, and Holmes, Booth and Haydens, Waterbury, Conn., has also removed from his old address, 1533 the Monadnock, to rooms 1129-1130, where he and Mr. J. H. McGill are now settled in a handsome set of offices where they will be pleased to receive calls from their many friends.

THE DETROIT ELECTRICAL WORKS are to be sold at Detroit on March 4, the property including the factory, machinery, manufactured goods, bills receivable, and 46 letters patent, some of which are regarded as being of considerable importance. The trustees are Louis Warfield and W. A. Jackson.

MR. J. R. WILEY, manager of the Chicago office of the Standard Underground Cable Company, of Pittsburg, recently made a business trip and reports that the amount of orders they are receiving is highly satisfactory and that they are kept hard at work all the time.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. MARCH 4, 1896. No. 409.

ELECTRIC LIGHTING.

WESTERN ELECTRIC IRON CLAD ARC DYNAMOS.

REALIZING that the ironclad armature has almost completely driven the surface wound machine from the market, in constant potential work, the Western Electric Company has designed and put in service a complete line of arc machines having ironclad armatures and other new features.

These ironclad armatures have been in use in increasing numbers for over a year without the loss of a single coil. This is a practical demonstration of the possibility of insulating an ironclad armature for high voltages, and once having accomplished that task, the mechanical superiority of the ironclad armature is unquestionable. The man who has spent twice as much time in replacing the bands on a burned-out armature

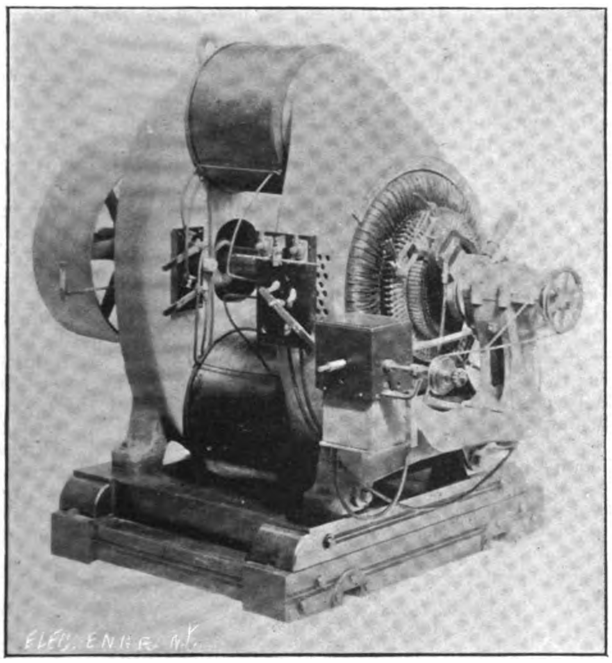


FIG. 1.—THE WESTERN ELECTRIC IRON CLAD ARC DYNAMO.

as he has in rewinding a burnt coil, will appreciate an armature in which the knocking out of a wedge gives complete access to a coil.

The general form of construction of these machines is shown in Fig. 1. The frames are of the bi-polar, horseshoe type, with the magnets horizontal . The magnet cores are of wrought iron and the pole pieces and yoke are of cast iron.

The pole pieces are divided in the center, thereby greatly reducing the cross magnetizing action of the armature. The pole pieces are so shaped that when the regulator is set to give an absolutely constant current at any load the field will be of the right strength to give the predetermined slight amount of sparking in whatever position the brushes may be set.

The bearings are of the self-oiling, self-aligning type, and are provided with visual oil gauge and drain. The pulley and end bearing is bolted directly to the yoke of the dynamo and the commutator end bearing rests on a brass bracket projecting from the lower pole piece. The bearing bracket is bored out at the same time the pole pieces are bored, so that the removal of the armature is a very simple matter. The bolt can be taken out and the bearing turned around the shaft until the foot is clear of its seat and the armature will then rest in the pole pieces and the bearing can be slid off with a very slight exertion.

The simple fact that the armature may be so easily and quickly removed for examination or repairs is a point that will be fully appreciated by all central station managers. The bearing may be removed in about five minutes, the pulley in three, and the commutator in ten. It may be re-

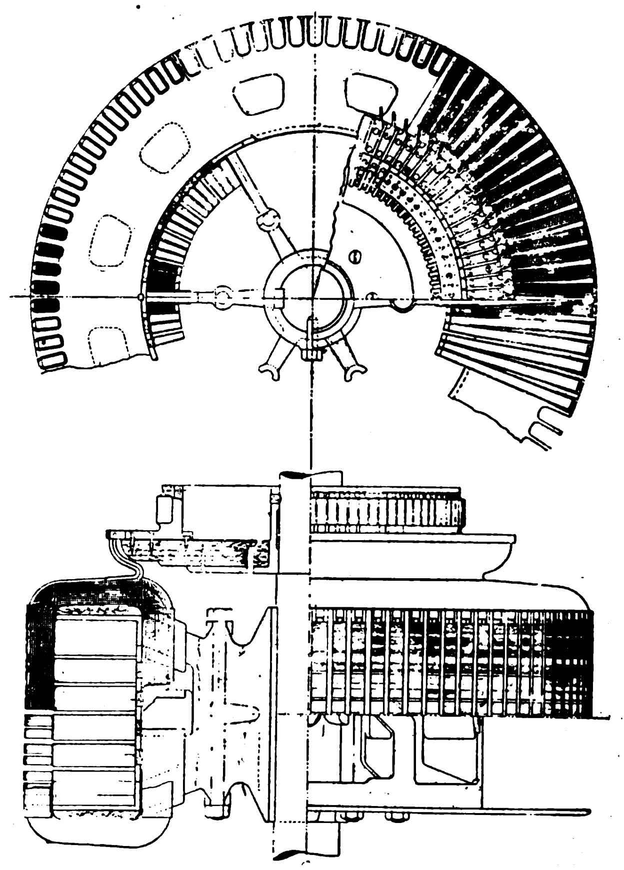

FIG. 2.

marked here that the time occupied by one man and helper in winding an armature coil is, on the average, 50 minutes for an 80-light machine, which is about an average size. The bearing seat affords a very convenient place in which to rest the armature, thereby doing away with the necessity of removing the armature completely from the frame.

The most vital part in all dynamos of high potential, is the armature. If the armature is not thoroughly insulated and designed for comparatively cool running, the machine is destined to a short life. The care taken in procuring first-class insulation of the armature is shown in Figs. 2 and 3. As will be seen, the armature is built up of very thin sheet iron rings mounted on a brass spider. The sheet iron rings have teeth similar to those in the standard incandescent ironclad armature; the coils are wound in the slots between the teeth and are firmly held in place by wooden wedges which are driven in over the top of the winding. The armatures are divided into a very large number of coils of comparatively few turns of wire. In this way the voltage in the individual coils is reduced to such a small amount that there is very little strain on

the insulation between coils and the voltage between segments of the commutator is so low that it is difficult to flash the machines under ordinary running conditions, and if flashing does occur the effect on the commutator is scarcely noticeable. By dividing the winding into a large number of small ventilated coils the accumulation of heat in the center of the coils is avoided, thereby preventing the slow roasting of the insulation which occurs in some machines.

The coils are insulated from the core in the slots by a trough which is built up of alternate layers of press board, mica and

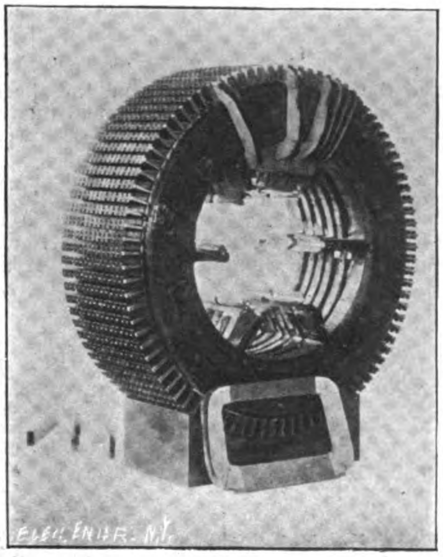

Fig. 3.—Armature Core Ready for Winding.

oiled paper, the sheets of mica being well lapped to avoid any chance of puncturing at the joints. The coils on the inside of the armature are wound in insulating troughs somewhat similar to the troughs in the slots, with the exception that they are narrower and deeper. The ends of the coils are insulated from the core; first, by wooden rings, which are placed at the ends of the armature and form rounded corners to wind over, as well as affording additional insulation; second, by built-up U-shaped troughs which overlap and extend in and around the inside and outside troughs. The result is, that each coil is wound in a separate trough built up of four overlapping troughs which effectually insulate it from each of the other coils and from the core. A complete trough is shown separate from the armature in Fig. 3.

The advantage of this form of construction is at once evident in case repairs become necessary, as any coil can be rewound without affecting the others in any way, and as there are no bands, all that has to be done is to slip the armature far enough out of the pole pieces to work on it and then take off the commutator and rewind a coil and put the armature and commutator in place again.

The 100 and 125-light armatures have a large space between the inside of the armature and the spider. On the 80-light and smaller machines the construction of the brass spider is such that the shaft and the greater part of the hub and spider can be taken out from the inside of the armature, so that there is a great amount of space on the inside of the armature and the facility for winding is very greatly increased. The inside and outside parts of the armature spider are drawn into perfect alignment again by six bolts with taper collars, as shown in Fig. 2.

In case one or even four or five coils of an armature become injured it is not necessary to rewind them at once, for if a coil is not short-circuited internally the terminals of the coil can be simply disconnected from the clamp on the commutator and a small jumper put across the same segments to which the coil was previously connected, and the machine can be run with no serious increase of sparking.

If any of the injured coils are short-circuited internally, of course the short circuit must be gotten out, or the whole coil may be cut out with a cold chisel. If this is done, it is necessary to take out the opposite coil also in order to keep the armature in running balance. A wooden wedge inserted in the place of the inner portion of the coil will serve to hold the other coils in place.

The following table shows the result of a test made on an 80-light machine, in which armature coils were cut out at various points:

No. coils cut out.	Volts.	Amperes without use of reduc. swchs.	Length spark.	Location of coils.
2	4,300	10.4	¼ in.	Adjacent
3	4,250	11.4	½ "	Adjacent
4	4,200	12	¾ "	Bunches of 4.
8	4,000	11.4	¼ "	Adjacent
12	3,800	12.2	⅝ "	Bunches of 2.
16	3,600	10.4	¼ "	Bunches of 3.R
16	3,600	13.2	¾ "	4 bunches of 2 and 8 single coils distributed around the Armature.

The spark is somewhat increased in length, but is not of a nature to damage the commutator.

The current may be reduced from that shown in the table to the normal amount, by the use of the reducing switches, without materially affecting the length of spark, as will be seen from the following test: A five-hour run was made, with sixteen coils cut out in four bunches of two and the other eight unequally distributed about the armature. The current was ten amperes and gave a quarter-inch spark. At the end of the run there was no sign of undue heating and the commutator was not injured in the least.

The all important factor producing long life in an armature, after good insulation has been secured, is that of ventilation. The success of the system of ventilation adopted is shown by a test in which two armatures were built just alike except that one was wound in the usual way, and in the other the coils were ventilated, as shown in the engravings. The former heated 80 degrees F. above the air after a 12-hour run, while the latter only heated 60 degrees F., after a 24-hour run.

The armature discs are supported by extensions on the spider. These points of support which are about two inches wide are directly over the spider arms, as shown in Fig. 2. Between the spider arms, in the open spaces, are laid small wooden blocks about one-quarter of an inch thick, which separate the armature coils from the discs and between every three or four coils on the inside of the armature are ventilating spaces. These ventilating spaces which are shown very plainly in Fig. 2 open into ventilating chambers in the brass ring which carries the armature discs and this space communicates directly with the spaces between the iron discs, which are, of course, open at the outside where the iron teeth come between the coils. By this means there is a free circulation of cool, fresh air in through the coils, coming in at the bottom and flowing up through the ventilating spaces between the armature discs and out between the armature teeth. In addition to this the brass spider arms are partially cut away where they pass through the winding at the bottom so that there is an additional opening for the admission of fresh air into the spaces between the armature rings. The iron armature rings are held apart in bunches of about sixty by radial strips of asbestos, which, from their action as a centrifugal blower, tend to keep the fresh air flowing through the armature.

The special feature of this system of ventilation and insulation is that the entire ventilating space in the armature may be filled up with carbon or copper dust, leaving the insulation of the machine as strong to resist the breaking down strain, due to the voltage, as it was before, for the reason that each

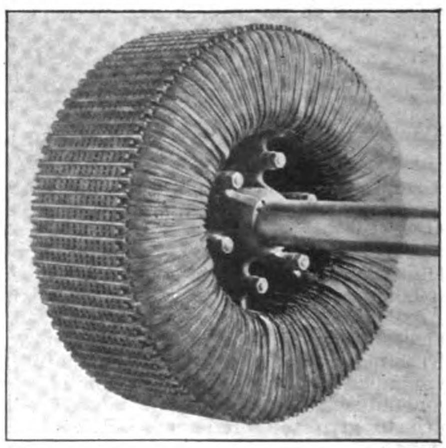

Fig. 4.—Armature Complete, Pulley End.

coil is insulated independently of the rest in a trough which completely protects it.

The mechanical superiority of the ironclad armature over the surface wound is most apparent when necessity requires it to be handled, either in placing it in the dynamo or moving it about the station. It may be rolled about the floor without injurious results, as it is absolutely puncture-proof.

The field coils are wound on paper spools 1/8 to 3-16 inch thick, which are built up and flanged over outside of the 1/2-inch wood veneering heads. The spools are held away from the iron core and the yoke and pole pieces by wooden wedges so that there is a large ventilating space all around the inside and at the ends of the spools. The construction of the spools is such that should this ventilating space become filled with dirt the coils are still effectually insulated.

On the yoke of the machine shown in Fig. 1 is mounted a pair of reducing switches which cut out part of the field winding. The lower switch is for the purpose of adjusting the spark at the brushes to the conditions under which the dynamo is running. When this switch is open the machine will run along without flashing under normal conditions, though the spark is in this way reduced practically to nothing. If there are sudden and great changes of load, it is desirable to have the machine run with a slightly longer spark so that it will not flash before the regulator has a chance to compensate for the change in the load; this can be accomplished by simply closing the switch.

The other reducing switch is for the purpose of reducing the current output of the dynamo so that if it is desired to run the machine part of the time at a lower current than 9.6 amperes this switch can be closed and the regulator adjusted to the lower current. In this way considerable fuel can be saved when it is not necessary to run the lights at full brilliancy.

The commutator, which is shown in detail in Fig. 2 and complete in Fig. 6, is built up on a very substantial disc of hardwood veneering which is mounted on a brass flange. This wooden disc is then faced with mica and each segment is screwed to it independently of the others. The segments are tapered slightly towards the inside, allowing slate wedges to be driven in between them, thereby protecting the mica facing from the action of any burning that might be caused by the flashing of the dynamos. The outside ends of the segments are held rigidly by a compound ring of mica and veneering and each segment is held in position on this ring by a machine screw and two dowel pins. The segments are insulated from each other by air spaces allowing both sides of each segment to be perfectly inspected and cleaned at any time when the machine is not running.

With an air insulated commutator the burning effect of flashing and short circuits is confined almost entirely to the brushes so that it is not necessary to turn down the commutator after bad flashing, as is the case with solid built commutators. The carbon brushes feed down and compensate for the burning as soon as it is over. All parts of the commutator which are connected with the circuit of the machine, are on the face of the wooden disc so that there are no parts behind the commutator which have to be cleaned to keep the insulation from

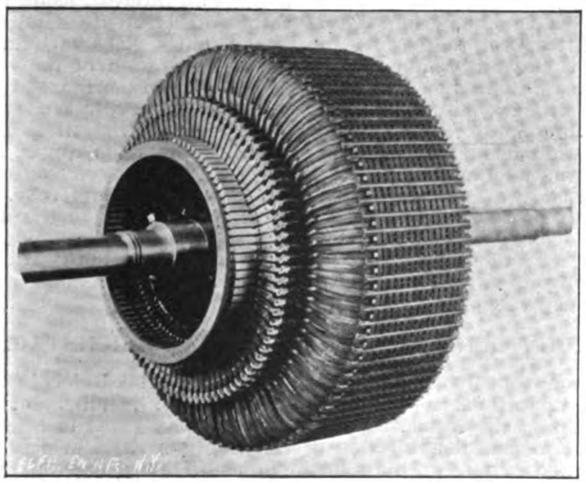

FIG. 5.—ARMATURE COMPLETE, COMMUTATOR END.

running down. Also all screws used in its construction are accessible from the front. The segments are increased in size at the working part so as to provide for a long life and also to hold the flashing as much as possible in the working part of the segments. This form of construction has the additional advantage that it is not dependent on slate or rubber or any other brittle material for its mechanical support and yet the mechanically substantial insulation is thoroughly protected by the slate wedges from the burning action of flashing.

The brushes are arranged to cover the commutator over the entire angle spanned by them, and whatever sparking occurs, is concentrated at the tip of the brush. At the brush tip is provided a small independent brush which is automatically fed down to compensate for the increased wear due to the spark-

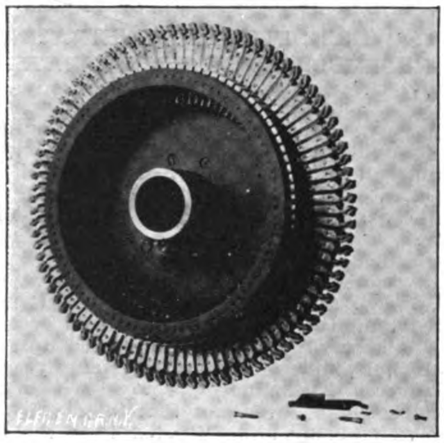

FIG. 6.—COMMUTATOR COMPLETE.

ing at this point. This independent brush is so narrow that the brush angle remains practically constant, no matter how fast the brush may be worn away by sparking. The tension of all brushes, there being four to each holder, is adjusted by vulcanite handles, carrying a worm screw, which slip down over ratchets; by turning the rubber handle carrying the worm screw the brush tension can be adjusted accurately, and when it is desired to replace a brush the handle and brush spring can be removed entirely from the brush holder and the carbon taken out and inspected or renewed.

In some of the older forms of carbon brush holders used on air insulated commutators, considerable annoyance was experienced from the noise caused by the chattering of the brushes. This has been almost entirely obviated by the construction adopted. In these brush holders the main brushes cover several segments at once and all the brushes are urged by springs in the direction in which the commutator rotates, so there is no chance for the brushes to vibrate. With these brushes it is not necessary to oil the commutator.

The connection board has a substantial slate base on which is the line switch and lightning arrester. The lightning arrester is shown at the top of the board in Fig. 1 and consists of two carbon pencils, one connected to each side of the line, which are held horizontally and in close proximity with a grounded carbon plate midway between them. As soon as the lightning jumps across, the arc is almost instantly blown out by the field from the pole piece of the dynamo. The arresters have been found to work very satisfactorily in long continued and severe storms.

The operation of the machines is fully equal to that of the old surface wound type. The lamps can be thrown off or on in groups equal to 10 per cent. of the capacity of the machine from full load down to short circuit or vice versa and the regulator will compensate for the changes without flashing the machine. Or the whole load may be thrown on or off instantly and the regulator will compensate for the change in a few seconds.

The machines withstand without injury the ordinary accidents of operation, such as open circuit and short circuit and either side of the circuit may be grounded to the frame and the circuit opened without injuring the insulation.

A test was recently made to ascertain the rise in potential at the terminals of an 80-light machine. A load of ninety lamps on a very short line was put on the machine and the line opened as nearly instantaneously as possible at the switchboard. The potential was taken at the terminals of the machine with a Weston voltmeter. With the machine running at 4,500 volts, the voltmeter swung up to 5,500 volts, when the circuit was opened; at a load of 3,300 volts, the needle swung to 4,400. This shows that there is no marked difference between the ironclad and surface wound machines in this respect. If the circuit had been opened in the middle of a long

line the rise in voltage and consequent strain on the insulation would have been so small as to be hardly worth figuring on.

The machines are all designed to run fourteen hours on any load from dead short circuit to full-rated capacity without heating in any part more than 70 degrees Fahrenheit above the surrounding air.

The Western Electric Company manufacture this type of dynamo for 50, 60, 80, 100 and 125-light capacity, and are also prepared to furnish these sizes for direct connection to the standard high speed engines.

LIGHT RAYS WHICH, IN THEIR PENETRATING POWER, RESEMBLE ROENTGEN'S X-RAYS.

BY N. D. C. HODGES.

The purpose of this note is to call attention to the properties in common of certain radiations which, while somewhat unusual in character, have been classed hitherto as light rays not essentially peculiar in their method of propagation, with those radiations which are now known as Röntgen's X-rays.

Fox Talbot, about 1840, first observed spectra in which the order of the colors was not as usual (red, orange, yellow, green, blue, indigo and violet), but in which the violet was less refracted than the red and other colors of great wave-lengths. This observation was not followed up at the time; in fact, it was not published for nearly twenty years. In 1860 Le Roux discovered that iodine vapor possessed not only a very remarkable absorbing power, but that the spectrum was abnormal, the violet being less refracted than the red. From that time till the present, anomalous dispersion has been frequently investigated by physicists and chemists; but the difficulties have been great, and comparable quantitative results have been few, as witness the labors of Le Roux, Christiansen, Kundt, Soret, Mach and Osnobischin, Wernicke, and others. However, the existence of the phenomenon is no longer denied, as it was by some soon after the announcement of its discovery; and fortunately it is possible very easily to get qualitative results, i. e., to break up a beam of white light into two parts, of which one, consisting of the rays ordinarily most refrangible, is less refracted by some substances than is the other, consisting of the rays of greater wave-lengths. In fact, De Klerker (Comptes Rendus, 1879) maintained that the anomalously dispersed rays were not refracted at all by the substance producing the dispersion. At any rate we have light rays not as subject to refraction as are ordinary rays, and in so far they approach Röntgen's X-rays in character. The question is, Have these two classes of radiations other properties in common?

To test the power of penetration which the anomalously dispersed rays might possess for substances usually opaque to light rays, I used a so-called "pocket kodak," carrying a strip of film sufficient for twelve exposures. This camera was placed in the closely-fitting pasteboard box in which it is sold, the shutter opened, the cover (lined with carbon paper) being immediately shut down. In this way sections 1, 3, 5 and 7 were exposed to pure sunlight (in so far as it could penetrate the pasteboard end of the box) for 5, 10, 15, and 30 minutes respectively. For sections 2, 4, 6, 9 (8 was accidentally allowed to pass unused) the exposure was not to pure sunlight, but upon the end of the box upon which the light fell was placed a prism formed of two microscope slides held together at an angle of only a few degrees, and in which a small quantity of a dilute alcoholic solution of fuchsine was held by capillarity. On development the film showed an increasing amount of fogging as the length of time the different sections had been exposed increased. But as section 8, which had not been exposed, showed a marked amount of fogging, it was evident that light had entered the camera in some way so as to reach the sections of the film which it had been assumed would be protected.

To avoid any overlapping effect and separate as completely as possible the parts of the film acted on by the pure sunlight from those acted upon by the anomalous rays, in the second experiment sections 1, 2, 3, 4 were, in succession, exposed to pure sunlight (so far as it could penetrate the end of the pasteboard box, as above) for 5, 10, 15, and 30 minutes, respectively; sections 5, 6, 7 were passed by without exposure, so as to furnish plenty of film to wrap about the first four sections and to separate the pure sunlight action from that which came later; sections 8, 9, 10, 11 were exposed for 5, 10, 15, and 30 minutes, respectively, to the anomalous rays, as before, the fuchsine prism being attached to the end of the box. On developing, the first four sections were found to be unfogged; a slight fogging appeared on section 6, and from there on the fogging increased with the length of exposure. Again, sections which would be amply protected from ordinary light showed a fogging which could have been produced only by rays which must have passed through the wooden sides of the camera and the paper of the box.

In order to increase any tendency to luminescence inside the camera, a strip of white blotting paper was inserted in the dark chamber of the camera and kept there through all the exposures. It will be understood that the pure sunlight had to pass through the side of the pasteboard box, and that it produced no fogging in the control exposures (which have since been repeated, but without the blotting paper), while the anomalous rays to produce the fogging must have passed through not only the pasteboard but also through the wooden sides of the dark chamber of the camera, and probably through the leather and wood covering of the camera.

It would appear, therefore, that the violet rays which result from anomalous dispersion of sunlight by refraction through a prism of fuchsine have a power of penetration for paper, leather, wood and black cloth—substances which are opaque to the whole light of the sun.

PROF. WOODWARD'S ALUMINUM VACUUM TUBE FOR GENERATING X-RAYS.

Prof. F. L. Woodward, of the Lawrence Scientific School at Harvard, has devised a new form of vacuum tube, by means of which excellent cathodographs have been obtained. As the sides of the lamp permit cathode rays to pass through them, the fact that with it cathodographs may be obtained contradicts the theory that a glass envelope plays an essential part in the generation of Röntgen rays.

This new form of vacuum tube is that of a cone, and its characteristic difference from the ordinary Crookes tube is that the walls of the lamp are of sheet aluminum, one-tenth of an inch in thickness. The base of the lamp is of solid glass, practically a plug fitted into the base of the aluminum cone with plaster of paris and made air tight. A metallic ring passes around the base of the cone and holds the sides of the cone firmly to the glass bottom. Through a point a little to the side of the center of the glass base passes the cathode terminal into the lamp, and at the end of this is fastened a platinum disc at such an angle as to be parallel with the side of the lamp. At the top of the lamp and directly connected to the metallic side is the anode terminal, and at the top of the cone is a glass tube with a stop cock, so that the air may be exhausted. This glass tube is also fastened in with plaster of paris, and bound by a metallic ring. A circular wooden disc is fastened inside the metallic cone, to prevent any collapse of the sides on exhaustion. By this construction it has been found that the difficulty from the absorptive power of the rays by the glass of the Crookes tube has been eliminated in a most marked degree.

As yet, Mr. Woodward has worked with this lamp with induced currents of between 25,000 and 30,000 volts, and with such power very clearly defined radiographs of the hand have been taken in five seconds. It seems from this that, with a higher current, say 50,000 volts, an instantaneous photograph may be taken and the heavier parts of the body readily photographed.

The new form of a vacuum tube has an interest, aside from its construction, from the fact that experiments conducted with it appear to disprove the theory that a glass vacuum envelope plays a significant part in the generation of the Röntgen rays. This theory was advanced by Röntgen himself, and was strongly supported by Poincaré. But Prof. Woodward has obtained excellent cathodographs from the radiations passing through the sides of the aluminum cone of his lamp. This supports another theory, to the effect that Röntgen and cathode rays are independently generated in a vacuum tube, but that the former alone have the power of traversing the glass envelope. The fact that clearly defined cathodographs of the hand were obtained in five seconds shows that Röntgen vibrations are greatly weakened in passing through the glass of the ordinary vacuum tube.

ROENTGEN RAYS IN THE GERMAN REICHSTAG.

Baron von Buol-Berenberg, president of the Reichstag, issued invitations recently to the Ministers, members of the Reichstag, the Bundesrath, and the German press to be present at a special exhibition of the Röntgen rays, which was given by Professor Spiess in the Session Hall of the Reichstag on Thursday, Jan. 30. The great hall was crowded and most of the Ministers were present. Professor Spiess, after making a number of experiments, delivered an explanatory address in which he suggested that science would soon be so developed that they would be able to photograph the contents of secret documents through the letter boxes. The only means of safety the Ministers had, he said, was to use letter boxes made of lead.

THE ELECTRICAL EQUIPMENT OF HAMMERSTEIN'S "OLYMPIA."

THE electric lighting of a large theater differs so essentially from that of ordinary buildings as to afford a vast opportunity for the ingenious arrangement of electrical devices and effects, and requires careful study in its design. Not only must the illumination be very great for the size of the building, but this illumination must be so arranged as to produce the proper aesthetic and scenic effects, and must be under instant and complete control, so that any or all the lights in the building may be dimmed or raised or thrown off or on at the will of the stage attendant, and above all things must be absolutely reliable. Crowds of people fill the building nightly, and if through the failure of some part of the apparatus the hall should be left in darkness a serious panic might arise. Only the best apparatus, therefore, should be used for theater lighting, and its installation must be carefully studied and thoroughly accomplished.

The lighting plant of Oscar Hammerstein's new "Olympia" affords a striking example of this class of electric engineering. The whole work was planned by and carried out under the supervision of Mr. John Thompson, Mr. Hammerstein's electrical engineer, and great credit is due him for the complete success of the plant.

The boiler room is located under the side walk at the north side of the building. It contains a battery of two boilers of the Campbell-Zell type, each of 500 horse power capacity at 80 pounds steam pressure. The grates are arranged for burning pea-coal, which travels on an incline from the bunkers without any labor of handling. An electrical tell-tale water level is being designed for the boiler room and will soon be in service.

Before reaching the engines, the steam passes through a Stratton separator, which effectually removes all moisture from it. The entire building is heated by exhaust steam from the engines, by direct and indirect radiation. The steam after leaving the engines passes through a Hine & Robertson grease extractor, where it is freed from its oil. It then passes to a Webster heater, and thence to the heating system, from which the water of condensation is returned and pumped into the boilers. All steam pipes are thoroughly covered, and of such a size and so well laid out that the whole heating system involves a back pressure of less than one pound per square inch.

There are two engines of the Corliss type, made by the Hewes & Phillips Iron Works. They have cylinders twenty inches in diameter, a 42-inch stroke and operate at a speed of 90 revolutions per minute. Each engine carries a 16-foot flywheel with a 38-inch double crowned face, driving by two belts a pair of generators. The belts are three ply, made by the Page Belting Company.

The four generators thus driven are of the ironclad multipolar type, manufactured by the Eddy Electric Manufacturing Company of Windsor, Conn. Each has a rated capacity of 100 kilowatts at 125 volts and 600 revolutions per minute, and in addition each machine will easily carry an overload of 25 per cent. for several hours. The frequent and sudden fluctuations in the load of the generators, due to the throwing on and off of a large number of lights, are very similar to the severe changes in load of street railway service. This point was considered by the manufacturers, and the machines were constructed to meet the same conditions as their street railway power generators. So free are the generators from any trouble from sparking that it is possible to throw the entire load off and on at the main switch without an indication of the machine that it is loaded or not, except in the tightening and slacking of the belt, and without any change in the "lead" of the brushes.

The sad accident that occurred at this building on the morning after its opening will be remembered by all. The steam pipe that caused so much sorrow and damage deluged the generators with a flood of steam and boiling water, and yet so thorough and perfect was the insulation that within a few hours, and in this soaked condition, each generator was operating at full load. This was certainly a most severe test of the reliability of the apparatus.

The generators are connected to the switchboard so that either one singly, or any number in parallel, may furnish current for the lighting system. Each generator is controlled by a three-pole main switch, located at the bottom of the marble switchboard. The switchboard also carries the field rheostats (which are arranged behind the board, the handle alone showing on the front), four 1,000 ampere ammeters, voltmeter and seven circuit switches; the last control feeders leading as follows: Theater front, music hall stage, music hall front, electric sign and lobby.

The electrical plant was installed by Messrs. H. B. Coho & Co., who deserve great credit for their arrangement and management of the matter.

The distribution of the electric power over the building is of great interest, alike from an engineering and from an aesthetic point of view. The conductors are everywhere carried in armored conduit. The control of light from the stage radically differs from that usually employed. An ingenious relay switch patented by Mr. John Thompson, the chief engineer, is the basis of the whole arrangement. The theater and music hall are both controlled by a bank of buttons, mounted on a single marble slab, 16 x 28 inches. The switches themselves are located in convenient parts of the building, and connected with the buttons. Aside from the cumbersome nature of the regular switchboard, which is thus avoided, the wiring to the relay switchboard involves a mere fraction of the copper that would otherwise be necessary. Further than this the construction of the switches is such that it is very easy to gang them; that is, to have all or any number operate by the pressure of a single button. This switchboard is very unassuming in appearance. The lights are controlled in brilliancy by rheostats. Each circuit has a handle swinging on a pivot, by means of which its light can be dimmed down to a faint glow. In addition, a handle swings a long bar carrying sectors, to which any or all of the rheostats' levers can be attached by a quarter turn of the handles, and thereby operate simultaneously. The great number of combinations that can be made to work in unison is at once apparent. For instance, assuming that the theater lamps are burning at full brilliancy, it is desirable to dim the side lights and the lights in the body of the theater, leaving the footlights and the lights in the flies burning, but not at full brilliancy. Locking all of the levers into the gang switch, the latter would be drawn forward until the footlights and the lights in the flies were dim enough. By a quarter turn of the handle controlling them they would then be left behind, and the dimming of the rest of the lights could be continued at pleasure. In like manner an almost indefinite number of combinations can be made, which will work harmoniously and with pleasing effect. The main lever has an adjustable extension which can instantly be brought into play to give a greater leverage. Two projector arc lamps light each stage. These lamps are very ingenious, the design of Mr. Thompson. The carbons are at right angles and the light of the positive crater is thrown directly forward without any reflector or lenses, though, of course, the use of these devices greatly increases the projecting power.

HAMMERSTEIN'S OLYMPIA, NEW YORK.

The decorations both in music hall and in the theater itself are strikingly beautiful. The chandeliers are hung with glass pendants, prisms and multifaced bulbs, and are probably the largest electric glass chandeliers in the country. The arms, and, in fact, all but the joints, are of glass, and are wired entirely from the inside. Both houses are lavishly decorated with papier mache work, painting and statuary, from the smallest cherub to the eight-foot heroic figure. The theater is finished in blue, while the opera house is in red. Besides the theater and opera house there is a concert hall, which is also elegantly appointed. Glass chandeliers and fitting decorations are everywhere and every arrangement is made for the comfort of patrons. Lundell fans set in holes just under the pitch of the roof keep the hall well ventilated.

The total number of lamps is 4,500 incandescent and 28 arcs. In addition, the stage projectors, the signs and the lights for the scenic effects constitute a variable portion of the equipment. On one scene alone in the opera "Marguerite" 984 lights were used for decorative purposes. These arrangements are largely designed and executed by Mr. Thompson, who has a very

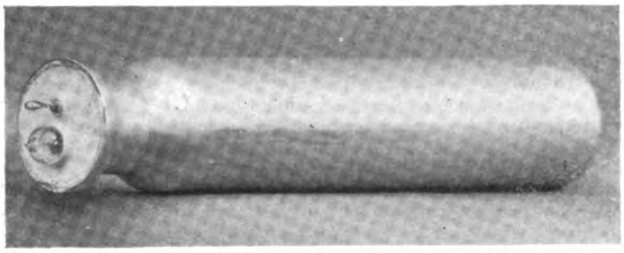
enviable record as a theater engineer. He was in charge of the first lighting plant in any theater—that of Booth at Baltimore. in 1877. Since then he has been continually employed at noted theaters at similar work, thus obtaining an experience which is very difficult to duplicate.

AN ALUMINUM VACUUM TUBE FOR X-RAY EXPERIMENTS.

BY WILLARD E. CASE.

In a former article, the author has shown that photographs could be taken of objects through solid plates by placing them between two condenser plates, or by making the object to be photographed, the anode; the cathode rays passing by it and casting the shadow of the anode upon the plate.

Heretofore sensitized covered photographic plates could be acted upon through solid bodies, with the use of the Crookes tube (which was made of glass and transparent, and through



THE CASE ALUMINUM VACUUM TUBE.

which the glow could be seen). The writer has constructed the tube here illustrated, which was made entirely of aluminum. being about 6 inches in length and 1 inch in diameter. The tube at one end is solid. Through the other end of the tube was inserted the cathode terminal and a very small miniature incandescent lamp bulb, which is used for the purpose of seeing whether or not there was a glow inside the tube when operated. The tube was then exhausted to the point of purple glow; perhaps not sufficiently high. The tube was connected up with an induction coil and the tube itself was made the anode.

For the first experiment, this tube was energized, was placed over an ordinary plate-holder, containing a sensitized plate and operated for some time in an absolutely dark room. No light could be seen from the outside of the tube, although some persons present insisted that they could locate the tube in the dark room. The sensitized plate was acted upon.

The shape of the tube and arrangement of the electrodes is not that which further experiment will probably determine to be the best, as it would appear that the rays were thrown in every direction in this particular form of tube. This is stated for the benefit of those who may wish to experiment further along these lines.

A MODEL RESIDENCE SWITCHBOARD.

BY WILLIAM C. HUBBARD.

In the plant recently installed in the residence of Mr. E. J. Berwind, New York, the idea that whatever beauty may exist in electrical installation should be concentrated at the switchboard, is carried out without sacrificing any desirable features; on the contrary many ideas leading to greater compactness and facility of operation have been embodied in the design.

The board, as shown in Fig. 1, is constructed of white Italian marble, with all the automatics enclosed in brass-bound separable bevel glass cases, set on marble shelves, giving the whole a handsome appearance.

The following services are controlled by means of this board: The street service, the current generated by a Siemens & Halske dynamo, driven by an Ideal engine, the storage battery charge and discharge currents; the water supply for both elevator and house use, the ventilating and heat regulating apparatus, the charging and ...scharging currents of the small storage cells used for operating the call bells, burglar and fire alarms and telephones. All the switches, measuring instruments and automatics being located on this board, the advantages of centralized control are obtained and the plant can be operated by one man, with the minimum of labor.

The house is wired with 3-wire mains and two-wire branches for outlets and lights, about 81 miles of tubing and wire having been used. The mains are brought down to the switchboard and connected to the three-wire busses on the back, Fig. 2, it having been found advisable under certain conditions of load distribution in order to secure more perfect equality of light, to operate on either the two-wire or three-wire systems, connecting the dynamo and batteries in multiple or series, as conditions might necessitate. These connections as well as the necessary crossing of the two outer bus bars are made by means of the double-throw switch shown at the lower right hand side of the board.

The charging or discharging of the batteries is accomplished by means of the double-throw switch, shown at the lower left side of board which also cuts in the proper automatics. The double-throw pivot switch in the lower center of the board

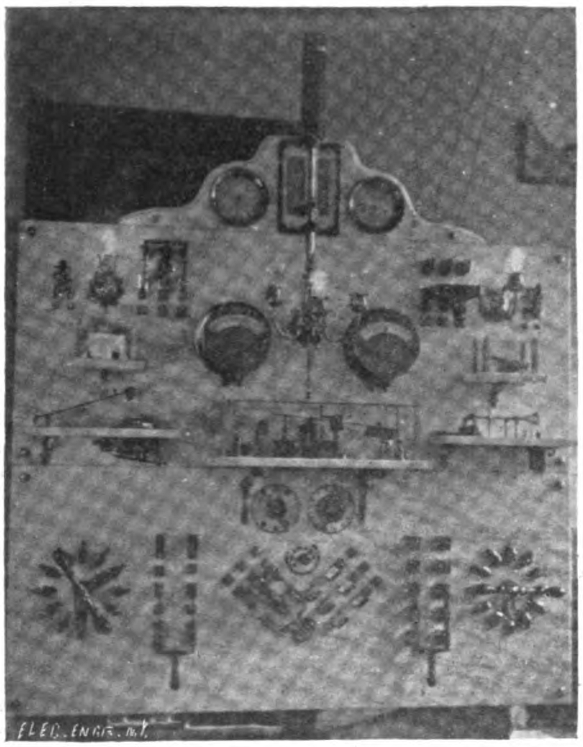


FIG. 1.—SWITCHBOARD, BERWIND RESIDENCE, NEW YORK.

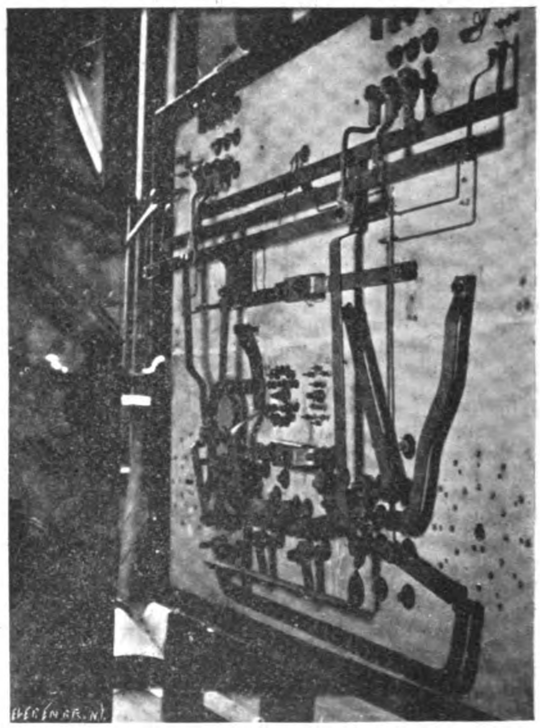

FIG. 2.—REAR VIEW OF SWITCHBOARD.

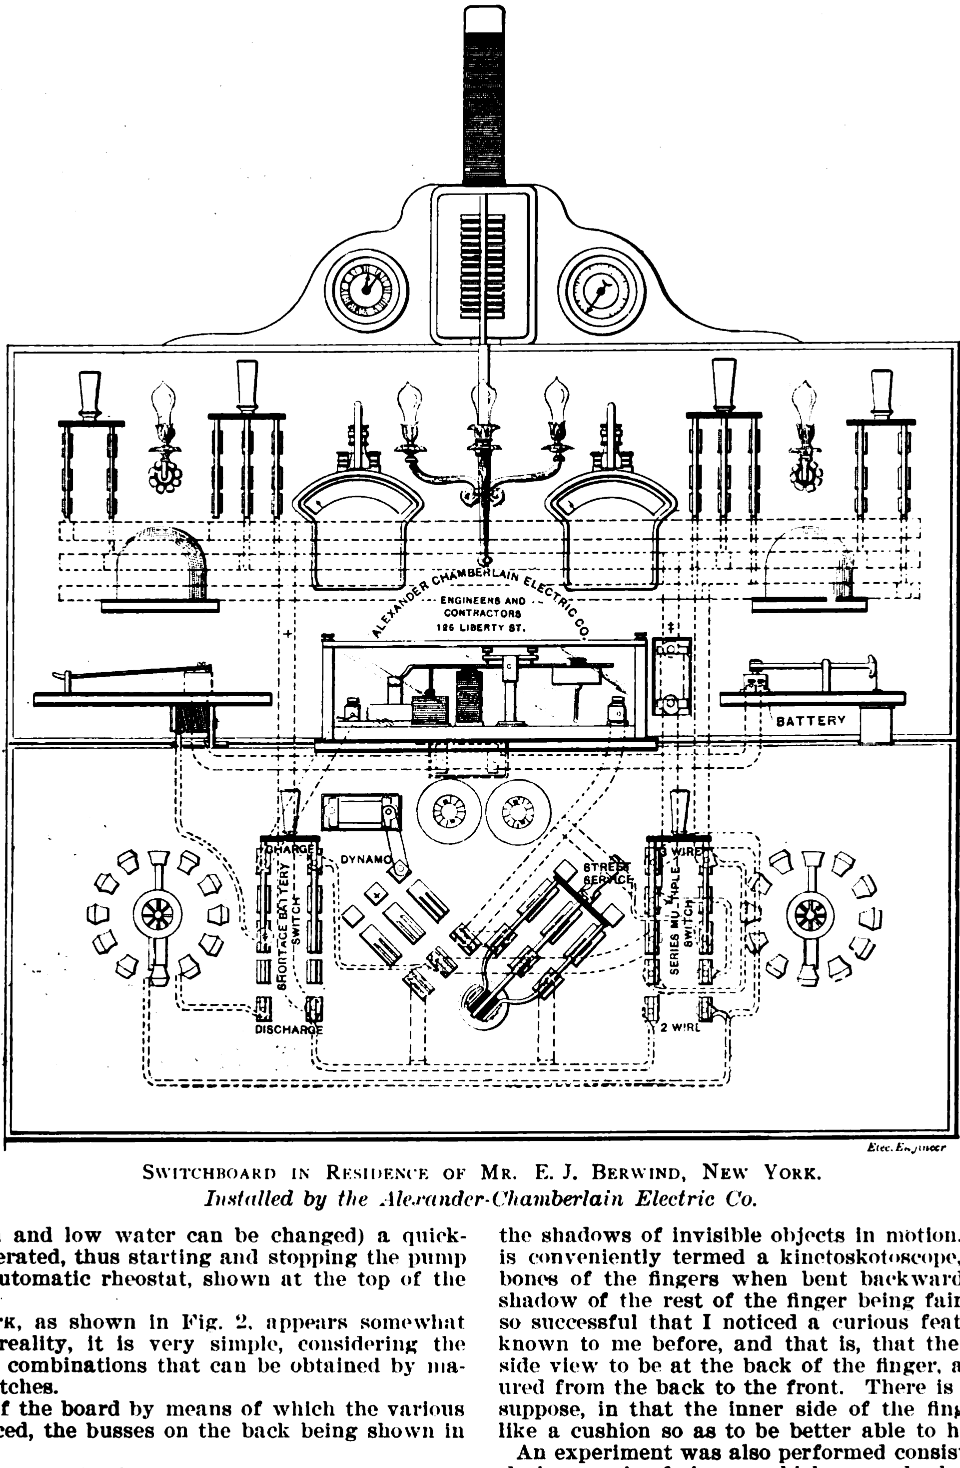
connects the house wiring with either the street service or the current from the plant.

In order to take current readings from different points a switch was designed and constructed which would connect the ammeter (a Weston detached shunt instrument) with any one shunt, and such are the construction and connections of this switch that there is practically no error in the readings. Readings of the E. M. F. are taken by means of a Weston voltmeter connected to the various points by the usual means.

All the water used in the house is supplied by an electric pump which forces the water into two tanks located in the attic, the water level in each being controlled by a cylindrical float having a rod rising from it and sliding in guides. By means of two adjustable collars (by shifting which the difference between high and low water can be changed) a quick-break switch is operated, thus starting and stopping the pump by means of the automatic rheostat, shown at the top of the board.

The bus bar work, as shown in Fig. 2, appears somewhat intricate, but, in reality, it is very simple, considering the many changes and combinations that can be obtained by manipulating the switches.

Fig. 3 is a plan of the board by means of which the various circuits can be traced, the busses on the back being shown in broken lines.



SWITCHBOARD IN RESIDENCE OF MR. E. J. BERWIND, NEW YORK.
Installed by the Alexander-Chamberlain Electric Co.

ELECTRIC LAMPS FOR TICKET COLLECTORS.

The ticket-collecting staff at Vauxhall have just had served out to them small electric lamps, which are fixed on their overcoats, the current being supplied from a miniature battery carried in the breast pocket. The experiment is to be tried for a month, and if it finds favor with the officials, electricity will supersede the old-fashioned and somewhat cumbersome hand-lamp. This arrangement has long been in use among the ticket inspectors on South London tramcars.—Westminster Gazette.

APPLICATION OF X-RAYS FOR MAKING VISIBLE OBJECTS IN MOTION.

BY EDWARD P. THOMPSON. M. E.

MR. M'KAY, of the Packer Institute of Brooklyn, has tested my idea mentioned in "The Electrical Engineer" of Feb. 19, as to the possibilities of exposing upon a fluorescent screen the shadows of invisible objects in motion. We saw in what is conveniently termed a kinetoskotoscope, the motion of the bones of the fingers when bent backward and forward, the shadow of the rest of the finger being faint. The result was so successful that I noticed a curious feature which was not known to me before, and that is, that the bones appear in a side view to be at the back of the finger, and very thin measured from the back to the front. There is a reason for this, I suppose, in that the inner side of the finger should be more like a cushion so as to be better able to handle objects.

An experiment was also performed consisting in opening and closing a pair of pincers which were absolutely invisible to the eye, but the shadow of the moving parts was clearly visible upon the screen. A chain was shaken back and forth, and the separate links moving relatively to each other were clearly visible. These experiments would prove that with the present condition of the X-rays the skeleton of a fish could be seen

to move backward and forward in the act of swimming, as well as the skeleton of all small objects while in motion, and performing the functions of life. I think that some of the best objects to be looked at while in motion would be, for instance, a bird, through which the rays would so easily pass except as to the skeleton. All youthful forms of life could be examined, very probably, by this means, and the motions exhibited.

My first experiment was an attempt to show that if a bone were broken in a living person's limb the fracture could be made visible by bending or stretching the limb. I began by taking a bamboo tube. Small iron rods were introduced from opposite ends until they met. These rods were invisible to the eye by ordinary light. When they were separated more or less, the gap between the rods within the tube became instantly visible on the fluorescent screen, and the rods could be seen to move away from each other through the opaque bamboo tube, while the latter appeared as if it were made of glass.

Another experiment produced the apparent effect of a solid passing through a solid. A large needle was driven through a block of wood, and the point of the needle could be seen to enter the wood. A somewhat similar experiment was performed with the hand. The needle was not driven through the flesh, but on the side of the hand opposite the eye, and the needle was clearly visible, and the moving point could be followed to different parts of the hand. This suggests a possibility in surgical operations, where it would be desirable to follow the point of the instrument through the flesh in vivisection. Another object seen was a fountain pen entering its opaque rubber cover.

I have for two or three weeks been trying different kinds of experiments, and I find that certain precautions are necessary in order to obtain the best results. In the first place, it is necessary, very probably, to show just how I made my fluorescent screen, because I find that others have tried to make it by crystallizing the chemical barium platino cyanide from a solution upon a sheet of paper. Others merely pressed the crystals upon a surface like filter paper. Such screens are of little value, especially as the substance then fluoresces blue which is nearly invisible, and only so in spots. By the following means, the results are so excellent and the screen is so luminous that the shadows are clearer than in the X-ray photographs. The cyanide should be powdered to the finest dust possible. Then some of the clearest colorless varnish should be put upon a piece of tracing cloth because the same is so strong, and so transparent to the fluorescent light which is produced. The powder may now be mixed very thoroughly and intimately with the varnish, so as to make a homogeneous mass, in quantity sufficient to spread over the cloth to a thickness of about one-eighth of an inch. This is mentioned because experimenters are likely to make the layer too thin. The reason for powdering the material is to produce a maximum amount of reflecting surface. The object of the varnish is to hold it together, and yet to permit the reflected rays of fluorescent light to become visible. The varnish should then be dried, but not necessarily perfectly dried. These directions should be followed very closely for good results.

The end of the tube which is directed towards the Crookes tube, and which contains the screen should be covered with photographers' black paper used for wrapping sensitive plates. Either side of the screen may be directed towards the Crookes tube. A very important precaution is to perform the experiments in a rather dark room. It may be light enough to be able to see objects, but if the room is very light, the eyes are not used to darkness, and therefore the experiments are not satisfactory, but if the room is quite dark, the screen in the closed tube appears immediately upon putting the eye to the hole in the tube, to be perfectly luminous. It will be more luminous under these precautions than luminous paint which has been held in the sunlight, and brought into a dark room, and yet if performed where the eyes are exposed to daylight the experiments are not so satisfactory. Another precaution is to have the electrical apparatus so arranged that the phosphorescent light from the Crookes tube is steady, which may be done, of course, by means of Leyden jars or other condensers. My idea of this new use of X-rays was conceived and attested Feb. 1, 1896.

SEEING WITHOUT LIGHT.—A CORRECTION.

In describing the device of Mr. E. P. Thompson, of seeing without light in our issue of Feb. 19, an error crept in. In the fourth paragraph, first column of page 191, instead of "The tube should contain a fluorescent light" read: "The tube should contain a lens."

PRESIDENT P. H. FLYNN, of the Nassau Electric Railroad Company, of Brooklyn, will, it is stated, resign during the next six months.

THE SOURCE OF THE X-RAYS.

BY

Elihu Thomson

To trace the rays to their actual source within the Crookes tube, there was placed within a pasteboard box, such as dry plates are packed in, two plates, one at the bottom, facing down, and another at the top, facing up. They were kept apart by wads of paper. One thickness of pasteboard covered each of them. This box was laid flat on the table and on its upper side was a small iron object of distinct outline, above which was suspended the Crookes tube. About 600 spark discharges through the tube (time, 8 minutes) effected an impression. The image on the top plate was found to be slightly larger than the object, while on the bottom plate, which was ⅞ of an inch below the first, a much larger image was impressed, showing a divergence of rays from some point above the object. Here, it may be remarked, the lower picture was produced through two thicknesses of glass, namely, that of the plates, which were relatively back to back.

On constructing a simple geometrical figure in the form of a triangle, using the longest dimension of the object image on the lower plate, for the base, and making the sides pass through the ends of a line ⅞ inch (distance of plates) from the base line and of a length equal to the longest dimension of the image on the upper plate; the apex of the triangle, is of course, the ray source. This was found to coincide with the cathode terminal of the Crookes tube, and, although, from the position of the terminal, the rays must have passed in large measure very obliquely through the glass, they were not in any way deflected from their straight course.

ON RADIANT MATTER.—III.

BY WILLIAM CROOKES, F.R.S.

RADIANT MATTER WHEN INTERCEPTED BY SOLID MATTER CASTS A SHADOW.—Radiant matter comes from the pole in straight lines, and does not merely permeate all parts of the tube and fill it with light, as would be the case were the exhaustion less good. Where there is nothing in the way the rays strike the screen and produce phosphorescence, and where solid matter intervenes they are obstructed by it, and a shadow is thrown on the screen. In this pear-shaped bulb (Fig. 9) the negative pole (a) is at the pointed end. In the middle is a cross (b) cut out of sheet-aluminium, so that the rays from the negative pole projected along the tube will be partly intercepted by the aluminium cross, and will project an image of it on the hemispherical end of the tube which is phosphorescent. I turn on the coil, and you will see the black

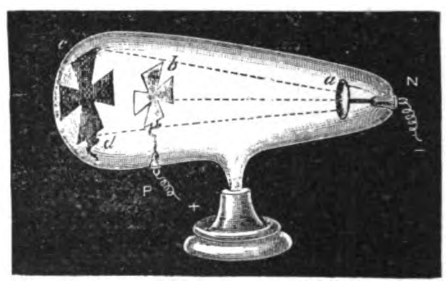


FIG. 9.

shadow of the cross on the luminous end of the bulb (c, d). Now, the radiant matter from the negative pole has been passing by the side of the aluminium cross to produce the shadow; the glass has been hammered and bombarded till it is appreciably warm, and at the same time another effect has been produced on the glass—its sensibility has been deadened. The glass has got tired, if I may use the expression, by the enforced phosphorescence. A change has been produced by this molecular bombardment which will prevent the glass from responding easily to additional excitement; but the part that the shadow has fallen on is not tired—it has not been phosphorescing at all and is perfectly fresh, therefore, if I throw down this cross—I can easily do so by giving the apparatus a slight jerk, for it has been most ingeniously constructed with a hinge by Mr. Gimingham—and so allow the rays from the negative pole to fall uninterruptedly on the end of the bulb, you will suddenly see the black cross (c, d, Fig. 10) change to a luminous one (e, f), because the background is now only capable of faintly phosphorescing, while the part which had

the black shadow on it retains its full phosphorescent power. The stenciled image of the luminous cross unfortunately soon dies out. After a period of rest the glass partly recovers its power of phosphorescing, but it is never so good as it was at first.

Here, therefore, is another important property of radiant

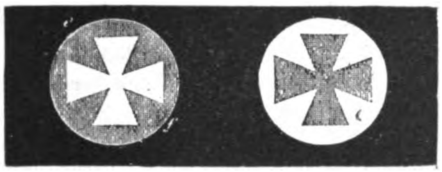

FIG. 10.

matter. It is projected with great velocity from the negative pole, and not only strikes the glass in such a way as to cause it to vibrate and become temporarily luminous while the discharge is going on, but the molecules hammer away with sufficient energy to produce a permanent impression upon the glass.

RADIANT MATTER EXERTS STRONG MECHANICAL ACTION WHERE IT STRIKES.—We have seen from the sharpness of the molecular shadows, that radiant matter is arrested by solid matter placed in its path. If this solid body is easily moved, the impact of the molecules will reveal its strong mechanical action. Fig. 11 repre-

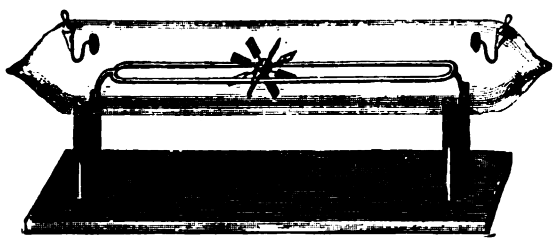

FIG. 11.

sents an ingenious piece of apparatus, constructed by Mr. Gimingham, which, when placed in the electric lantern, rendered this mechanical action very plainly visible. It consists of a highly-exhausted glass tube, having a little glass railway running along it from one end to the other. The axle of a small wheel revolves on the rails, the spokes of the wheel carrying wide mica paddles. At each end of the tube, and rather above the center, is an aluminum pole, so that, whichever pole is made negative, the stream of the radiant matter darts from it along the tube, and, striking the upper vanes of the little paddle-wheel, causes it to turn round and travel along the railway. By reversing the poles the wheel can be arrested and sent the reverse way; and if the tube be gently inclined, the force of impact is observed to be sufficient even to drive the wheel uphill.

This experiment therefore shows that the molecular stream from the negative pole is able to move any light object in front of it.

LETTERS TO THE EDITOR.

FUSE SHUNTS ON MAGNETIC CIRCUIT BREAKERS.

In the Feb. 26th issue of "The Electrical Engineer" is a letter from Mr. James H. Bates concerning automatic magnetic circuit breakers. Mr. Bates recommends the use of automatic magnetic circuit breakers on motor cars and urges the use of carbon final breaks to prevent arcing of the main switch jaws of circuit breakers.

While we agree with him that a carbon break is an excellent means for preventing blistering of the main contact jaws, still we cannot leave his letter go by without drawing attention to the advantage of the use of the fuse shunt protection to the jaws of the magnetic circuit breaker. There are several very important advantages in the use of the fuse shunt. First, the means of keeping tally on the motorman the number of times he opens his circuit breaker. Too much stress cannot be placed upon this feature, as one of the chief reasons railroad companies are adopting circuit breakers for their cars is to cut down the power station consumption, and if a record is not kept of those motormen who are continually opening the circuit breakers, the advantage sought for is thwarted.

Second. The use of fuse shunt protection permits the manufacture of a less complicated form of construction than would be by using carbon final break.

Third. In event of circuit breaker opening under conditions where the current rises just to the current flow necessary to move armature, thus tripping the catch, throwing main switch out, the fuse will not open immediately upon such switch movement. This enables a car to be brought to a standstill in event of an emergency reversal of a single motor equipment. Of course, in event of a "dead short circuit" or a heavy "ground" the "blowing" of the fuse is practically simultaneous with the opening of the main switch.

Fourth. It goes without question if "blistering" and "burning" of contacts can be entirely overcome, the types of circuit-breaker embodying such a feature, would be better adapted for the equipments of street railway work than one which would blister if certain parts were not kept in certain adjustment.

I am glad that Mr. Bates has taken the stand he has, as there is no question but a great saving can be effected by the use of automatic magnetic circuit-breakers on cars.

W. E. HARRINGTON.

Philadelphia, Feb. 27, 1896.

X-RAYS NOT IDENTICAL WITH CATHODE RAYS.

Why is it that nearly all your contributors insist on confounding the cathode rays, which have been known since the experiments of Crookes, with the new rays discovered by Röntgen, and which, for the want of an appropriate name, he has temporarily named "X-rays"? He has himself plainly shown in his presentation of the subject, and expressly states that the X-rays "are not identical with the cathode rays, but are produced from the cathode rays at the glass surface of the tube."

I must confess the confusion referred to led me considerably astray until I read the translation of Röntgen's paper in your issue of February 12. In order to be more specific, the X-rays are not deflected by a magnet (according to Professor Röntgen), nor do they proceed perpendicularly from the cathode plate, nor do they resemble cathode rays or any other kind that we know of except in their rectilinear propagation and chemical action on sensitive plates.

Another confusion which I note particularly in Mr. Robertson's paper of your current issue, ought not to pass without notice. This is a tendency to assimilate the new rays with magnetic lines of force. Those who do this have apparently forgotten that the lines of force are not the direction of propagation of energy or anything else. They are merely the direction of the attraction, and as such are static, so to speak, while anything in the nature of rays or waves is dynamic, nor can I see that there is any means by which one can be transformed into the other.

Perhaps with the confusions above mentioned the unscientific word "cathodograph," with the prima facie more ridiculous, but not more abortive, "raygraph," will disappear and give way to a better.

GEORGE W. COLLES, JR.

Boston, Mass., Feb. 26, 1896.

FACT AND FANCY IN CATHODOGRAPHY.

I wish to correct some of the worst errors made in the daily papers, which, however, perhaps have already been attributed to the reporters and printers by those who have had any experience in interviews. I did not perform any experiments at the Edison laboratory. It was at the Edison Lamp Factory. I there tested some tubes which Mr. John W. Howell was kind enough to have manufactured for me. I did not say that I could see the heart beat. I know nothing about future developments and possibilities. I did not invent the idea of seeing a bird during actual flight and thereby be able to solve the problem of flying machines. This was invented by some reporters, who became exceedingly enthusiastic upon my imparting to them the knowledge of my acual propositions and results. The most and very successful experiments were performed by me, by the cordial consent of Prof. McKay, at the Packer Institute, Brooklyn, N. Y. Some early and preliminary experiments were also made for me by Prof. Pupin, of Columbia, College, New York.

E. P. THOMPSON.

New York, Feb. 28, 1896.

LUCID AND EXHAUSTIVE.

Mr. Wetzler's article on "The Edison Electric Illuminating Company of New York," in the Jan. 8 number of "The Electrical Engineer," is one of the most lucid and exhaustive articles of the kind which it has ever been my pleasure to read. It should be studied by every one interested in central station work. Please accept my hearty congratulations.

CONTENTS.

SUPPLEMENT.

THE BALTIMORE TUNNEL ELECTRIC LOCOMOTIVE.

THE action of a number of steam roads in equipping some of their branches with electricity may be considered a sufficient argument as to the recognized superiority of electrical propulsion over steam direct on short lines. But to what extent electricity is applicable to the operation of general trunk line service is still an open question, though it has been the subject of quite active discussion. The series of papers on this subject by Mr. William Baxter, Jr., which are now appearing in "The Electrical Engineer," are probably the most exhaustive which have yet been written on the subject. We will not forestall the conclusion arrived at by Mr. Baxter as the result of his analysis of the conditions as they exist at the present time, but it is perhaps to be regretted that he did not have at his disposal the results of the tests of the General Electric Locomotive in the Baltimore tunnel, which we print elsewhere. These tests, made by the aid of the well-known dynagraph car of the Pennsylvania Railroad, are the first authentic records of an electric locomotive comparable in power with such as would be required for trunk line service, and hence deserve more than passing notice. These tests show, as was to be expected, that the electric locomotive exceeds in smoothness of operation the steam locomotive, and that broken couplings and other trouble caused by the varying crank positions of the drivers would be practically eliminated on roads equipped electrically. As to tractive power and the ability to pick up a load from dead rest, enough was shown to place the electric locomotive at least abreast of the steam. Another important feature brought out by these tests was the efficiency of the electrical system, which is shown to be higher than with steam direct. Altogether the results obtained are eminently encouraging, and they will undoubtedly have an important effect on future work of this character.

ELECTRIC LIGHTING IN MASSACHUSETTS.

FEW documents reach us that are more valuable as bearing upon the commercial conditions of electric lighting in this country than the annual reports of the Board of Gas and Electric Light Commissioners of the Commonwealth of Massachusetts, and we are glad to receive the eleventh in the series, just issued. The insight obtained from such reports into the nature and scope of the business can only be understood by those who actually handle and study these documents for themselves; and, while we think there are definite limits to be set to the powers of such bodies, we cannot believe that work of the kind here brought to notice can be other than beneficial to the interests whose relations with the public and with the stockholders are governed.

It would appear from this report now before us that the electric lighting companies have suffered in common with other industries of like nature, dealing directly with the public. The year 1895 was even worse than 1894, and we hope that the bettering conditions of 1896 will set the companies squarely on their feet again. As it is, we find a total revenue of $3,822,-196, and a total profit from all sources of $1,227,809. Against this there were charges of $234,444 for interest, $487,148 for dividends, $565,287 for depreciation and $123,177 for sundries. These actually show a deficit in the balance sheet for the year of $182,248, whereas in 1894 the companies pulled through with a surplus, after everything was paid, of $51,275. It would seem proper to reduce the dividend rate on such a showing, yet none of the companies are extravagant in that direction. One company pays 8½ per cent., three or four pay 8 and thence they straggle down to 2 per cent. Out of a total of 62 companies 33, or more than half, paid no dividends at all. The

gas companies in the State averaged much better, and their rates of dividend ran up in several cases to 10 and 12 per cent. At the same time, it is worthy of note as proo. o. the rapid growth of electric lighting that while the gas companies of the State, so long established, for the most part, paid out $1,086,878 in dividends, the electric companies paid out not far short of half as much. Many of the gas companies are also, as is well known, electrical current producers.

A noteworthy feature of lighting in Massachusetts has been the tendency there towards municipal ownership, and evidence of this condition of affairs is seen in the statistics of this report. It appears that official reports relative to action about such plants for gas or electric lighting—chiefly the latter—were received from no fewer than 238 towns and cities of a population over 1,500 each. It is lucky that precipitate action is not possible, or the increase in public debt would certainly be alarming. Out of these municipalities only 24, or a bare 10 per cent., took any action; the other 212 remaining as they were for the present. The number of such plants in actual operation is still limited to a dozen, of a total 2,330 horse power, and they appear to be fairly well run, although it is difficult to see any particular cause for jubilation over their economies of public money.

One of the functions of the board is to protect existing companies from unfair new competition if they are doing their work well, and another is to prevent them from an undue issue of securities based on insufficient assets. Both duties seem to be carefully and honestly discharged. Such work is of a delicate and difficult nature, yet when well performed it must go far towards enhancing the stability of the investments, and this is something that electric light companies can heartily apreciate and welcome.

THE ELECTRICAL EXPOSITION.

ALTHOUGH it is two months before the meeting of the National Electric Light Association and the holding of the Electrical Exposition in connection therewith in this city, there are already many indications that both will be a great success and go far towards marking a distinct revival in all the old electrical industries, as well as the springing into existence of many new ones. The association is taking vigorous measures to make its convention memorable for good, useful work, and we are glad to learn that it has, even thus early, secured the promise of a large number of valuable contributions, some of which, indeed, are of the highest degree of importance. This fact will in itself secure a large attendance from all parts of the country of those specifically interested in electric light and power; but it has a further value as marking the early return that the association is securing from its progressive action and its laudable desire to stimulate the electrical arts at this juncture.

The exposition is certainly destined to enjoy great success. The proofs of the interest of New Yorkers in it are already numerous. Electricity touches modern life on so many sides that there really seems to be no end to the variety of the exhibits and the miscellaneity of the people to whom they appeal. It is evident now that in some lines the exposition will far surpass any previous attempt of the kind, and that these lines will be peculiarly those that appeal to the public imagination and purse. Desperate as general financial conditions have been, electrical industries would have known no hard times had the public been made as well acquainted as it ought to be with the endless ways in which electrical appliances can minister to its comfort and happiness. When people are enabled to see what they can do and how cheaply they can secure all the new inventions, a stimulus will be derived which will not only do enormous good to electrical trade in New York, but send revivifying influences throughout the country.

Illustrative of the remarks we have just made are the plans of the local Edison company, which is going in with the determination to show how thoroughly a modern central station as an inexhaustible reservoir of current can supply well nigh innumerable needs for light, heat, power, ventilation, sanitation, amusement, medical treatment, etc. We venture to say that the average city public has absolutely no idea of the conveniences that lie literally at its door, waiting to be recognized and used, and we shall be very much surprised if the local company does not derive a handsome direct return from its enterprise in the inquiries that it sets on foot from new customers of all kinds, and the orders that it books for current, for lights, motors and other apparatus. We presume other local companies will follow suit along these lines, which are educational and helpful in the best sense.

ROENTGEN RAY PROGRESS.

IT was to be expected that so radical a demonstration as that of Prof. Röntgen would be followed up closely, and that it would lead to other, if not as startling, at least more important results. Viewed from the standpoint of theory, evidence is rapidly accumulating to establish the fact that there is a class of rays having actinic power, which pass through most organic matter with ease and which are absorbed in varying degree by the metals and other inorganic bodies, but which thus far have been found to be not subject to the general laws controlling vibrational energy. Analogous, if not identical, rays, it would seem, are present not only in ordinary sunlight, but in the arc and incandescent light as well, so that many of the experiments performed with Crookes tubes can be made with the sources of illumination just mentioned, though the time required makes longer exposures necessary. Just to what extent these rays exist in sunlight is attested by the experiments made by Mr. N. D. C. Hodges, which are given elsewhere, in which it is shown that fuchsine has the power of anomalous dispersion, so that the violet rays have the power of penetrating substances usually opaque to light. No doubt, other substances will be found to have the same effect. Prof. Elihu Thomson has also continued his experiments in this direction, and details some interesting results obtained by him.

Viewed from the practical standpoint, the influence of the X-rays on fluorescent substances has already been taken advantage of in the practical construction of apparatus for observing the motion of the bones in the living body and similar not less startling performances. Mr. E. P. Thompson, who has been vigorously prosecuting these experiments, shows what precautions are necessary to obtain the best results. No doubt, we shall soon find apparatus of this nature among the indispensable requisites of every surgical operating room. As to the forms of vacuum tubes designed to generate the Röntgen rays to the best advantage, we note this week two types. One of these, constructed by Mr. W. E. Case, takes the form of a cylinder, while Prof. Woodward, of Harvard, has adopted a conical form.

As we go to press a cablegram from London announces that a Mr. J. G. Vine has been able to photograph at one end of a wire objects exposed between two vacuum tubes at the other end of the wire. The same experimenter declares that he will soon be able to photograph objects at any distance by means of the X-rays. This news seems almost too good to be true, but, after the confirmation of Prof. Röntgen's experiments in every detail, one feels reluctant to reject as entirely improbable even the most doubtful story involving the use of the Röntgen rays. If this announcement shall be based on fact, it would seem to pave the way to the long sought for "seeing by electricity." Perhaps a seeing attachment to the telephone set may be the next inducement offered to subscribers.

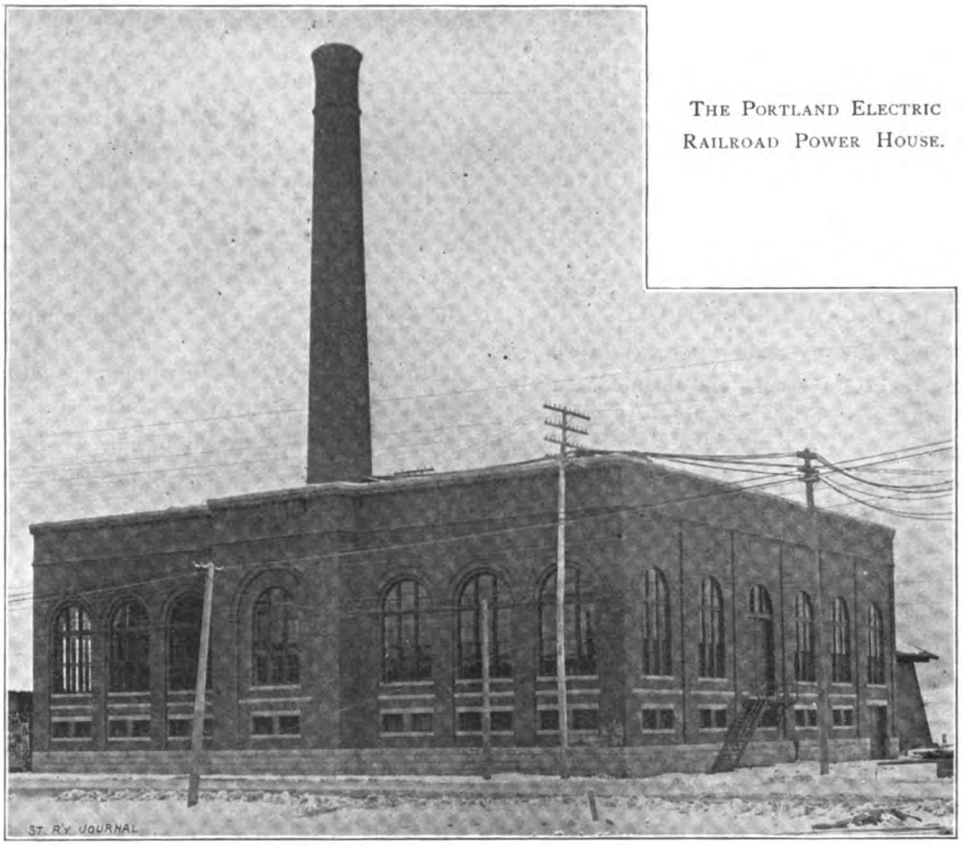
Electric Transportation.

THE PORTLAND, ME., ELECTRIC RAILROAD.

EARLY in the spring of 1895, the Portland Railroad Company, of Portland, Me., decided to change their motive power from horses to electricity, and in the beginning of April, ground was broken for the new power house, and the following month work began on track and line construction. The road, which is now completed, is in every respect a model, and railroad managers about to embark in a similar undertaking would find it to their interest and advantage to visit Portland and study the arrangements adopted.

POWER HOUSE.

The power house is located near Deering Bridge, on the water front, convenient to coal and water. Being built on reclaimed land, piles had to be driven, about 1,650 in all being employed for foundations. The piles were sawed off about one foot below mean high water line and concreted around with Portland cement concrete, one foot deep, flush, with the piles, then capped with granite blocks of such dimension that every capping stone rested firmly on at least three piles, and on top of this the foundation was built.



THE PORTLAND ELECTRIC RAILROAD POWER HOUSE.

The building itself is a substantial brick building with ornamental front. The inside dimensions of the engine room are 110x50 feet. The boiler room is 110x49 feet. Twelve feet of the boiler room is partitioned off by a wall and used for office, machine shop, oil room and storage room. The office and machine shop are on a level with the engine room floor and with entrance to the same from the engine room. Below the office is the oil room, which is built fire-proof throughout, and above the office is the storage room and lavatory.

Fronting on the street, in the engine room, a bay is built, 4 feet deep, in which the switchboard is located, flush with the inside line of the engine room wall. The feeders are brought from the switchboard inside of the bay, through the roof and from there over to the poles. No wires of any kind are visible inside of the building.

In the engine room there is also a traveling crane of 30 tons capacity, capable of handling the heaviest piece of machinery in the station. The traveling crane as well as iron trusses were furnished by Maguire & Jones, of Portland, Me.

CHIMNEY.

The chimney, which is located in the boiler room, is 16x16 feet square at the bottom and continues so about three feet above the roof of the building, where it commences as a round chimney, tapering to near the top, where it flares out in a neat design, giving it a very handsome appearance. The height of the machinery from the base is 145 feet. The inside diameter of the core is 6 feet 8 inches. The contractors for building and chimney were Messrs. Ridlon & Son, of Portland, Me.

ENGINE ROOM.

The present engine installation consists of three direct connected generators, room being provided for future extensions. Two of the generators are of 400 kilowatt and one of 200 kilowatt capacity. The 400 kilowatt generators run at a speed of 100 revolutions per minute; the 225 kilowatt at a speed of 120 revolutions per minute. The generators are the multi-polar ironclad type steel frame, built by the General Electric Company.

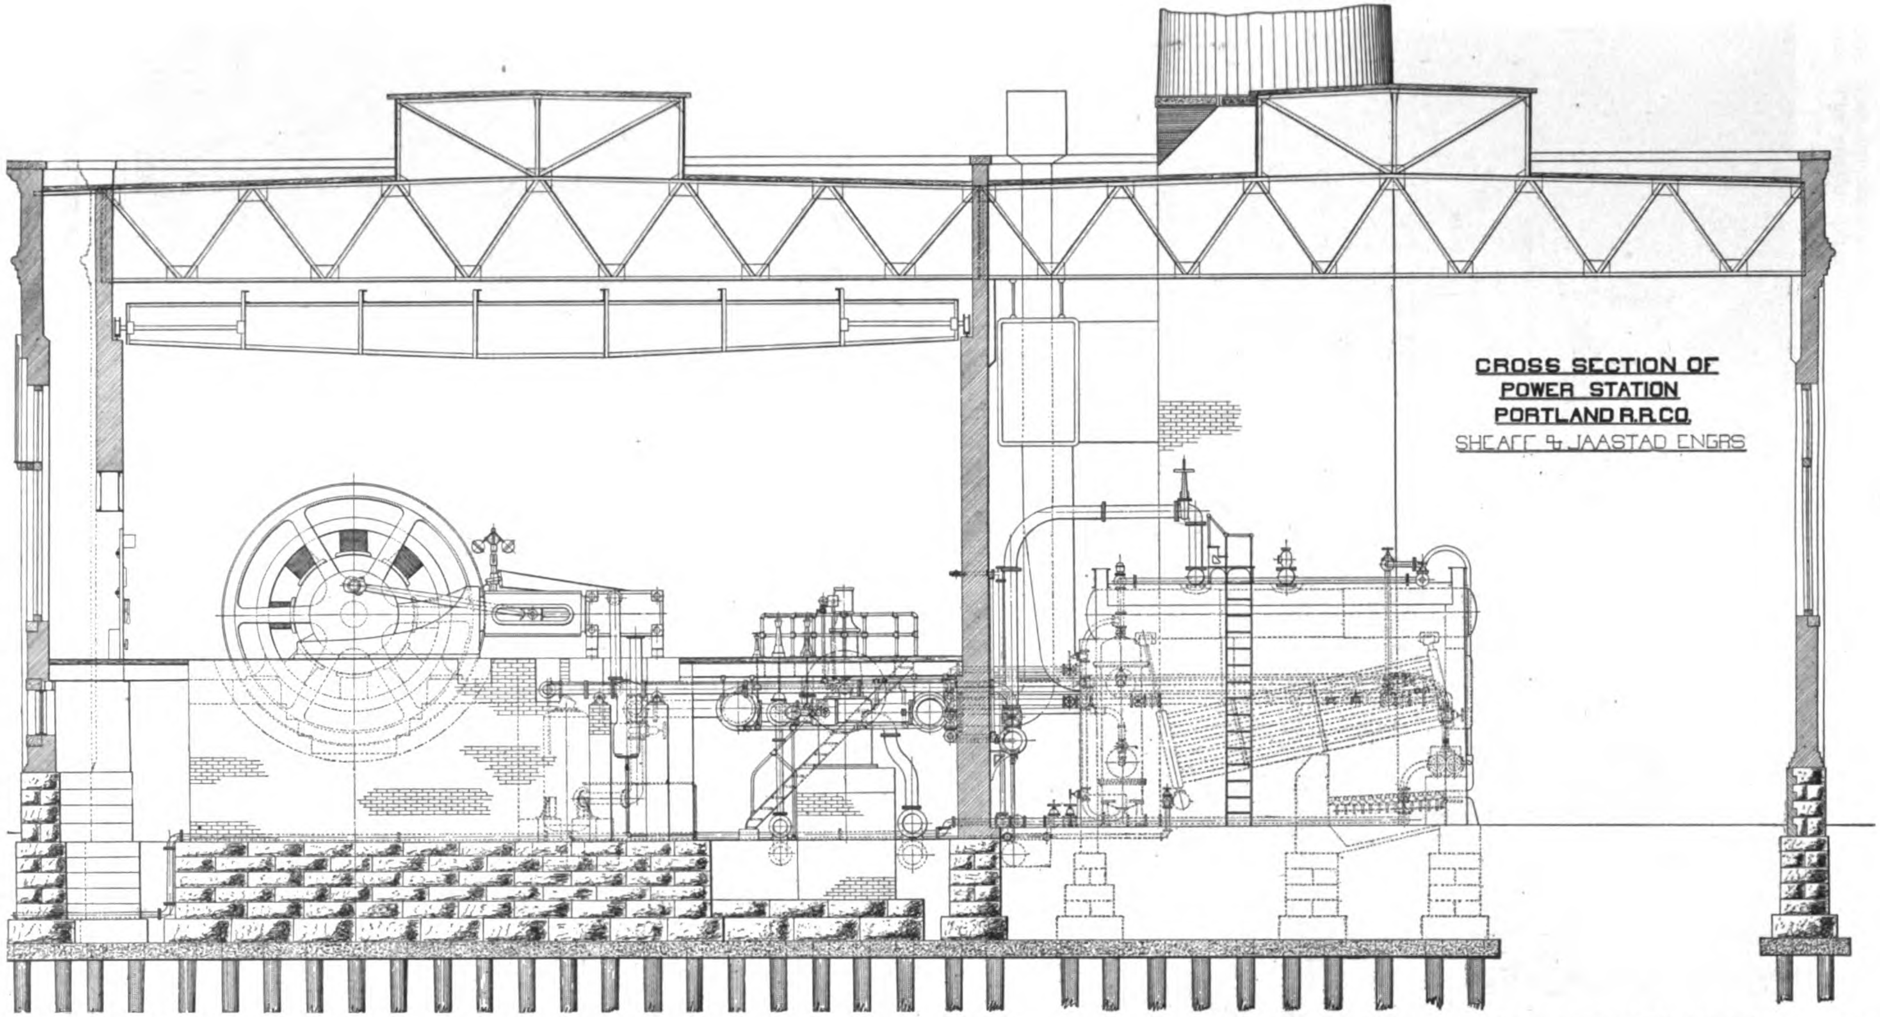
The engines are of the horizontal cross compound, condensing type, built by the E. P. Allis Company, of Milwaukee, with cylinders 14 inches by 26 inches by 36 inches for driving the 225 kilowatt and 18 inches by 34 inches by 42 inches for driving the 400 kilowatt generators These engines were built extra heavy throughout, so as to be able to withstand the excessive strain, due to the great variation of load that will necessarily arise on a road like this, where there are many very heavy grades. The engines are so arranged that either side, high or low, can be run independently, condensing or non-condensing if so desired.

There is one independent vertical flywheel condenser, of the E. P. Allis make, connected to each engine. These condensers are so arranged that their steam cylinders come up through the floor, making them easy of access, as shown in the sectional view on page 241.

BOILER ROOM.

In the boiler room there are at present two batteries of Babcock & Wilcox latest improved water tube boilers, each of a rated capacity of 500 horse-power. The boilers are all faced with white, glazed brick and present a very attractive and clean appearance.

In the boiler room there are two feed pumps 10 inches by 6



PORTLAND ELECTRIC RAILROAD POWER HOUSE.

SECTION OF ENGINE AND BOILER ROOM.

Sheaff & Jaastad, Consulting Engineers.

inches by 12 inches, built by the Blake Manufacturing Company, of Boston, Mass. Either pump is amply large to take care of the whole plant.

HEATERS.

There is one heater between each engine and condenser in the engine room, and one auxiliary heater in the boiler room, built by the Goubert Manufacturing Company, of New York.

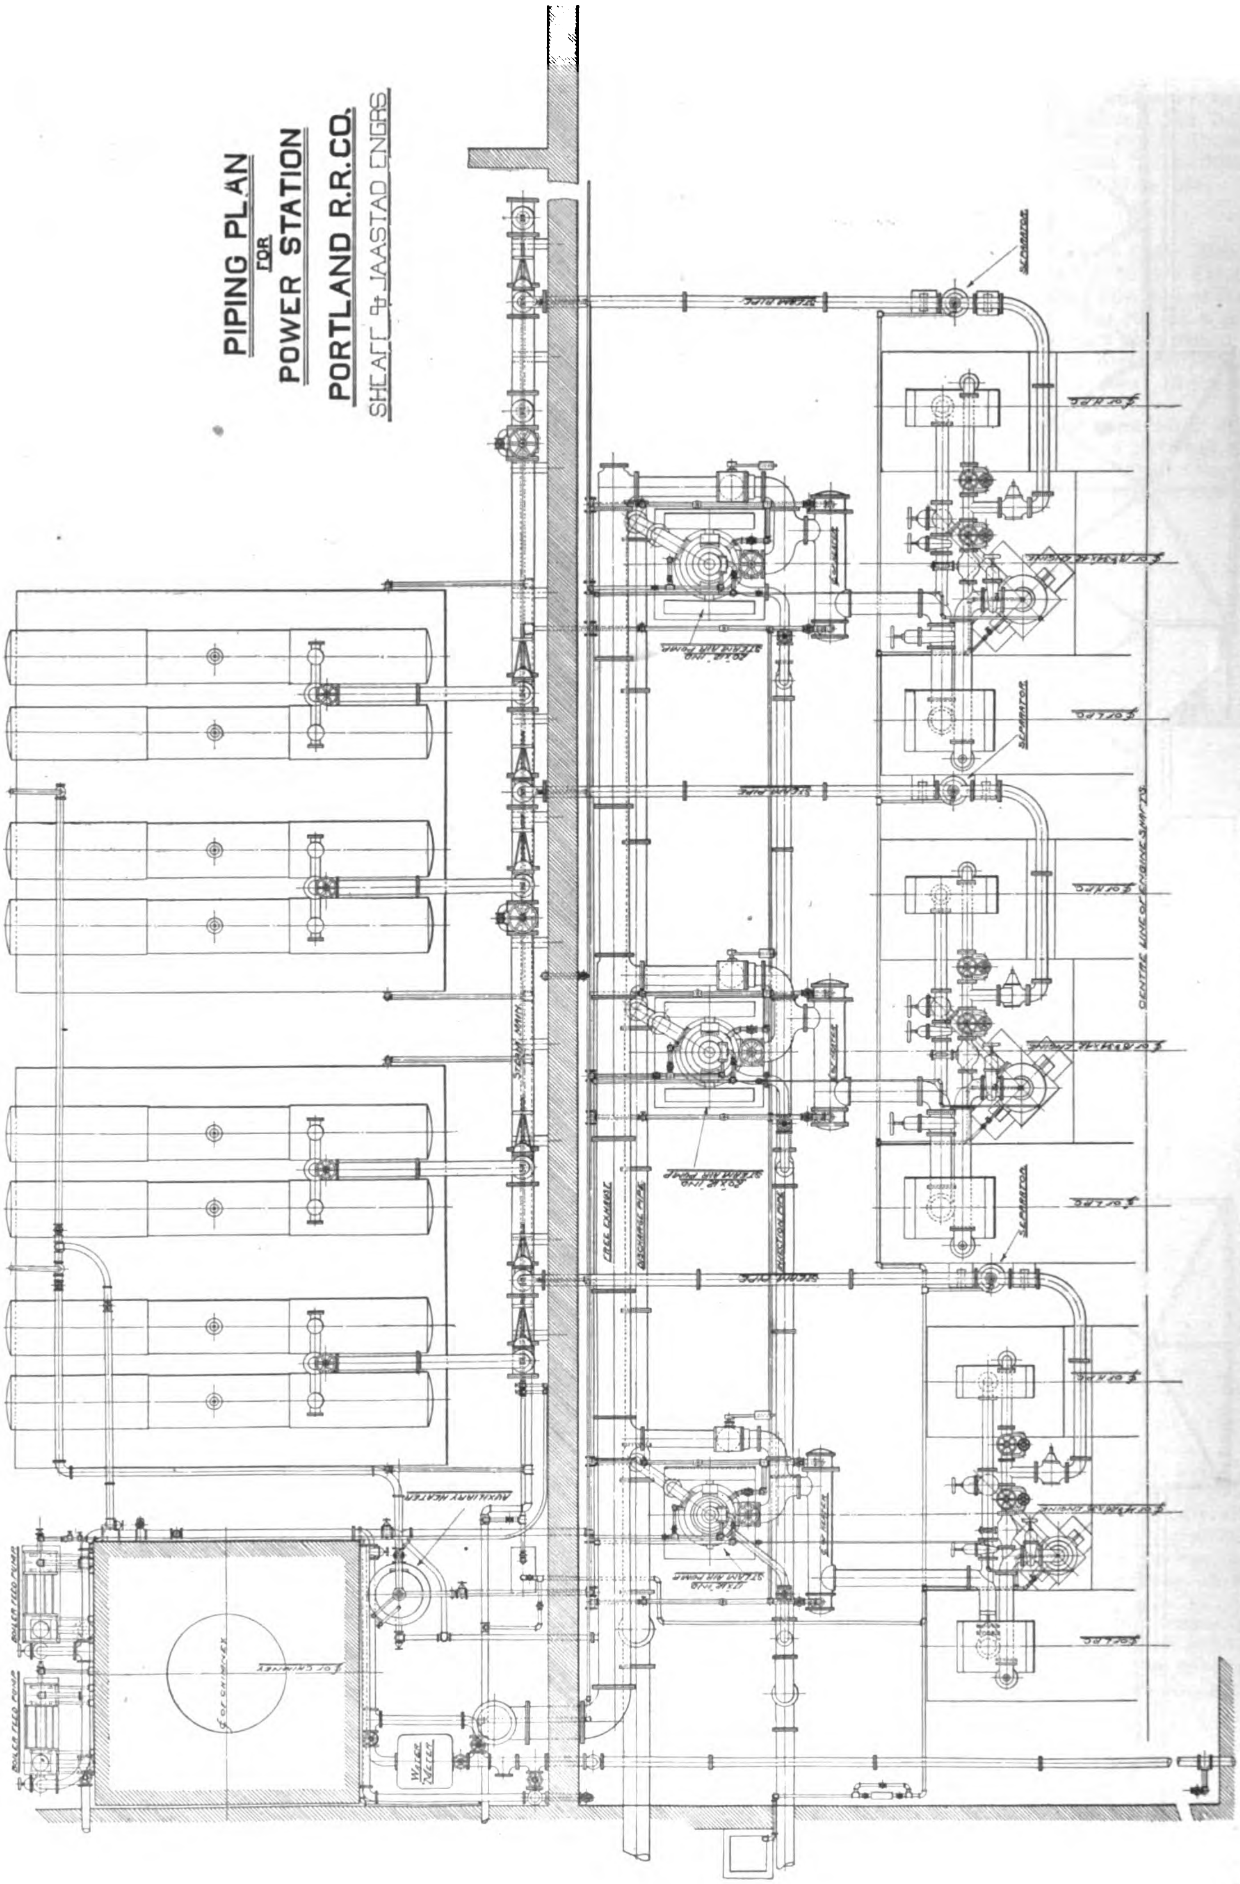
PIPING.

The steam main is carried on adjustable brackets bolted to the wall, back of the boilers in the boiler room, and in such proximity to the boiler room floor that the valves can be conveniently reached and operated from the floor by hand. The steam from the boilers enters this main through 8-inch pipes bolted to the nozzle of the boilers. This 8-inch pipe has a long bend so as to take care of the expansion and contraction.

The steam pipes to the engines from the main are carried through the partition wall, between engine and boiler room, as shown on the piping plan on page 242, under the engine floor to a Stratton separator, located near the throttle valve of each engine. As will be noted on the plan, these pipes are also provided with long easy bends so as to better take care of the expansion, and at the same time retard the speed of the steam as little as possible.

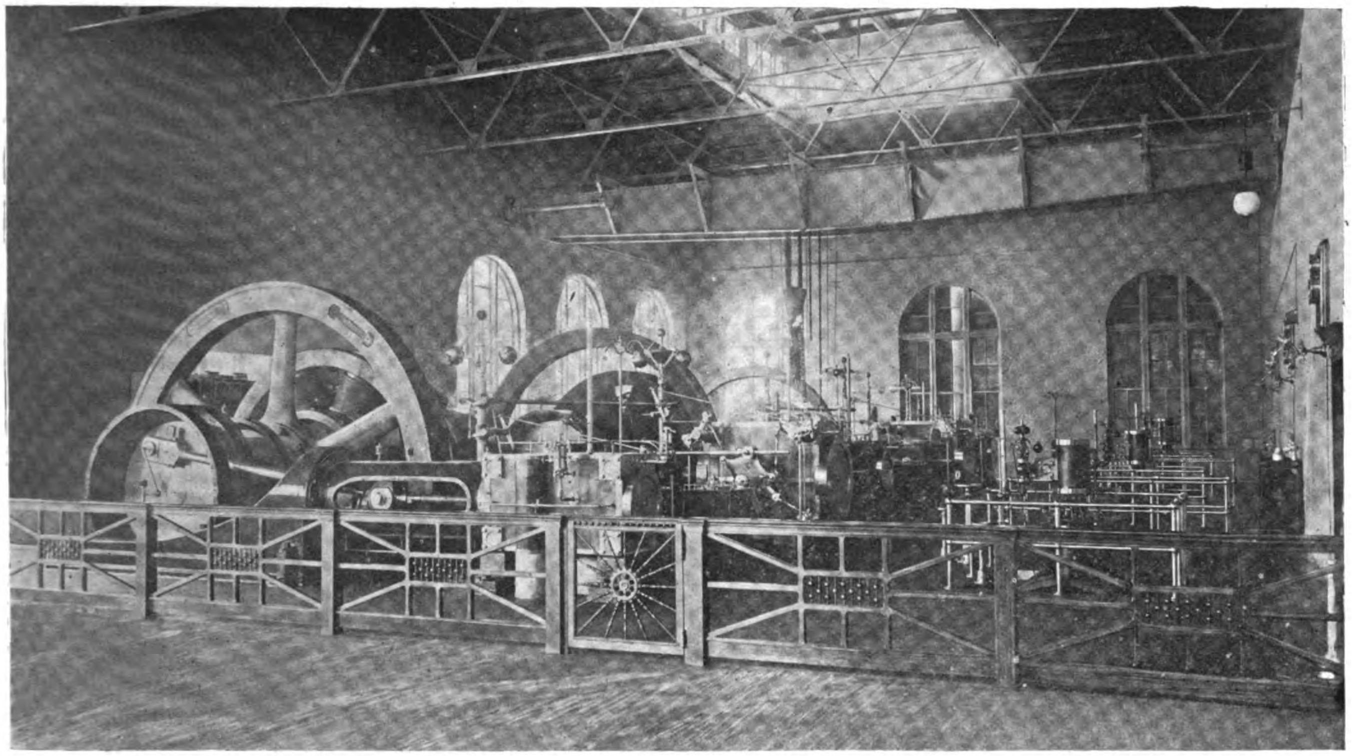
The exhaust steam, after leaving the engines, goes through a heater into the condenser, or it can go around the condenser out into the free atmosphere, as the case may be, dependent on whether the engine is running condensing or non-condensing.

The free atmosphere exhaust pipes from all the engines con-



THE PORTLAND ELECTRIC RAILROAD POWER STATION—PLAN OF STEAM PIPING.

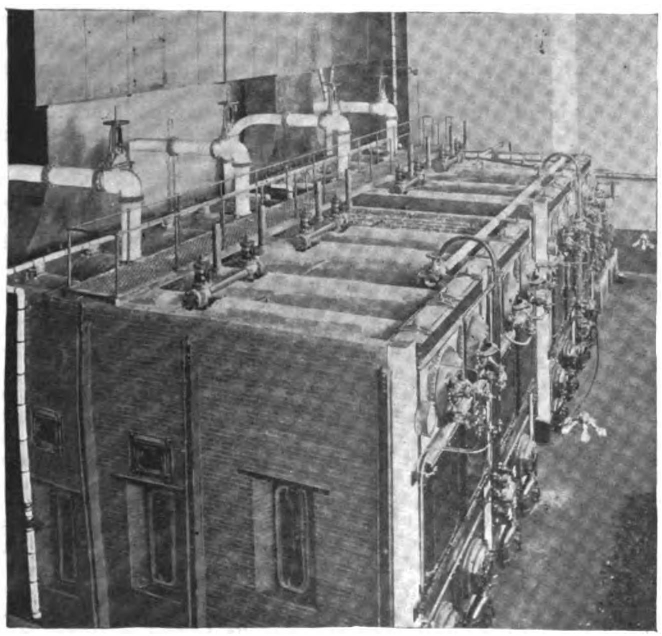
nect into one main exhaust pipe, which is carried to the boiler room, then up through the roof, ending in a Stein exhaust head. The suction pipe to the condensers is provided with a strainer placed in basement inside of building, by-passed, and so arranged that it can readily be gotten at and cleaned. The overflow pipe from the condensers discharge into the river.



The Portland Electric Railroad Power House.—View of Engine Room.

FEED WATER.

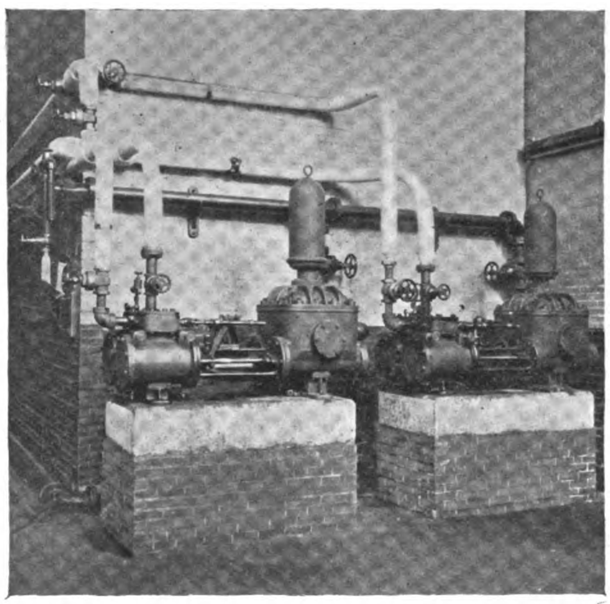
The feed water, which is city water, passes through a meter to the pumps in the boiler room, from where it is pumped first through the primary heater in the engine room, where it gets heated to from 125 to 130 degrees, then to the auxiliary heater in the boiler room, where the temperature rises to from 200 to 212 degrees, at which temperature it enters the boilers.



The Boiler Room.

The piping for this is so arranged that any or all of the promary heaters can be cut out and the water pass direct from the pumps through the auxiliary heater to the boilers, or the auxilary heater can be cut out, and it passes through the primary heaters direct to boilers, or all heaters, primary and auxiliary, can be cut out and the feed water can be pumped direct into boilers.

It is to be noted that the piping is so arranged that a complete break-down is impossible, as everything is in duplicate, with the exception of the steam main, which, however, by valves is divided into sections so that if anything should happen to one of the sections the remainder can be operated.



The Boiler Feed Pumps.

All drips from steam piping, separators and receivers are carried back to the boilers by the Holly return gravity system. It is also to be noted that all valves in the engine room base-

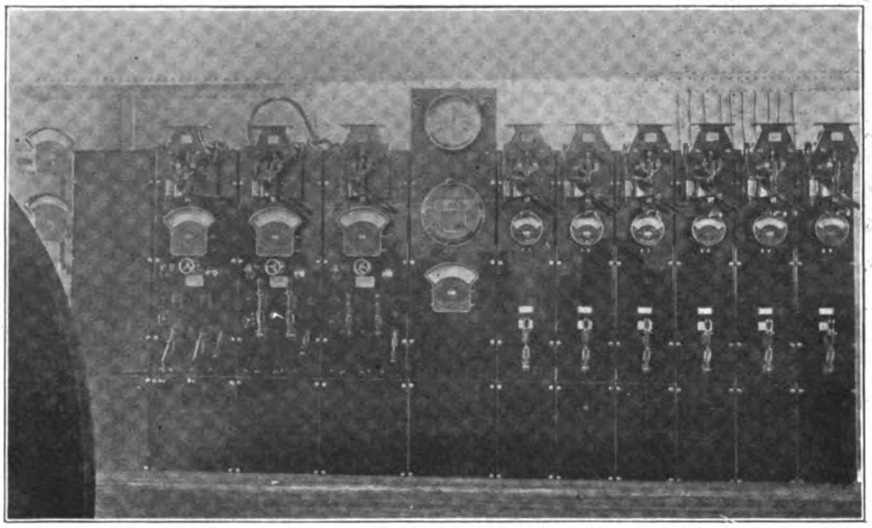
ment can be operated from engine room floor, they being provided with long stems and valve stands bolted on to the floor, shown in the view of the engine room on page 243.

TRACK CONSTRUCTION.

The tracks on the streets within the city limits are laid with 9-inch, 90-lb girder rails, on ties placed 2 feet 6 inches on centers. The track is thoroughly ballasted with clean, sharp gravel and paved with granite blocks. The rail connections are 38 inch, 12-bolt joint plates, double-bonded with No 0000 Chicago rail bonds. On the suburban lines 58-lb "T" rails are used, furnished by the Pennsylvania Steel Company. The special work was furnished by the Pennsylvania Steel Company and the Johnson Company. Messrs. Arthur Hodges & Co., of Boston, were the contractors for the track construction.

OVERHEAD WORK.

There are nine 500,000 circ. mils feeders leading out of the power house to the different lines, and in no place on the line is the maximum drop more than 10 per cent. The material used in the overhead construction was furnished by A. & J. M. Anderson, of Boston, Mass., and the contractors for the line work were M. K. Kendall & Co., of Boston, Mass.



THE SWITCHBOARD, PORTLAND ELECTRIC RAILROAD.

CARS.

The cars, open and closed, as well as snow-sweepers, plows, etc., were built by J. G. Brill & Co., of Philadelphia. The inside finish of the closed cars is in mahogany with plush covered seats. They are all artistically decorated and well lighted with incandescent lights, and heated by electric heaters.

The cars are equipped with the General Electric Company's "G. E. 800 motors and K.2 controllers.

That the railroad company is thoroughly alive to the ever-increasing demands on electric roads, as a means to outdoor enjoyment, is shown by the fact that they have purchased a large tract of land five miles out of Portland, converting it into parks and pleasure grounds. It is located on the Presumpscot River, and is one of the most delightful of the many picturesque spots in the State of Maine.

Great credit is due to the officers of the road and to their consulting engineers, Messrs. Sheaff & Jaastad, of Boston, who furnished all the plans and superintended the work of construction.

ELECTRIC SIGNALS ON THE PENNSYLVANIA R. R.

A new system of electrical signals for the starting of trains from Union Station at Pittsburg has been adopted by the Pennsylvania Railroad. It consists of long metal arms extending from the roof of the train shed to within a few feet of the top of the cars, one being directly over each track. On the end is affixed a lantern, covered on the side next the head of the train, with a red slide. When a train is ready to leave, the gateman will close the gate and push a button, which will cause the red slide to fall, showing a white light to the engineer. The latter cannot start his train until he "gets the block," and this places the starting of trains in the hands of the gateman. The system has been tried with success in the Broad Street Station, Philadelphia.

EXPERIENCE WITH THE ELECTRIC LOCOMOTIVE IN THE BALTIMORE TUNNEL.

AFTER a short period of experimental work, electric locomotive No. 1 on Aug. 4, 1895, took up the regular freight service through the Belt Line Tunnel of the Baltimore and Ohio Railroad in the City of Baltimore. The tunnel, which is the largest "soft dirt" tunnel ever built, extends from the present Camden passenger station of the Baltimore and Ohio Railroad, a distance of 7,350 feet north under the heart of the city.

Shortly after locomotive No. 1 had been put into service, and had given an exhibition of its ability to haul the heaviest freight trains, it became a matter of general interest as to how much it could pull and how fast it could go. The locomotive was therefore given a trial at hauling several of the passenger trains at high speeds, which it did satisfactorily to all concerned. As the conditions for operating the passenger trains entirely by the electric locomotive could not, on account of track facilities, be perfected until the new Mount Royal station, at the northern portal of the tunnel, was completed, it was decided to operate them in the meanwhile by coke burning steam locomotives. The new Mount Royal station will be ready in April or before, and preparations are now being made to then operate all trains, both freight and passenger, by the electric locomotives.

It was shown, from the few trials made with passenger trains, that not only could the guaranteed speed of thirty miles an hour be attained, but speeds of thirty-five and forty miles, with 500 ton trains, were possible. An exhibition of high speed was made with the locomotive running light up the 0.8 per cent. grade, and a speed of sixty-one miles per hour was attained for a short time, without the slightest trouble from trolley or motors. Several of the many exhibitions made by the locomotives in pulling heavy loads have been described in the newspapers. Probably the most striking was when two trains were coupled together and hauled through the tunnel. For some reason the freight trains had become "bunched" on the Washington division, and when they did get through they came so fast that it was decided to have the electric locomotive haul them two at a time. The first composite train, therefore, consisted of forty-four cars, loaded with coal and lumber, two regular steam freight engines and a steam "pusher" engine. The whole weight was approximately 1,900 tons, and was equivalent to about fifty-two loaded cars. The steam locomotives did no work to assist the electric locomotive. The start was made easily and gradually, but when the train was in the tunnel and entirely on the grade the steady, heavy pull was too severe on a defective coupling near the head of the train, and it parted. After coupling together again, the electric locomotive started the heavy train, with all drawbars stretched —no slack in the train—and accelerated it to a speed of twelve miles an hour, without slipping a wheel, and in every way with the greatest ease. It reminded one of the start of an ocean steamship, so noiseless was it and free from any manifestations other than those of mighty power. The current recorded on the ammeter was about 2,200 amperes during the acceleration period, and after the train was up to speed it settled down to about 1,800 amperes. The voltage on the line

was 625. By reading the amperes we were able to readily compute the drawbar pull, and found it to be about 63,000 pounds. All four motors were in series, and we were, therefore, getting the maximum pull for that current.

It may be of interest to steam railway engineers to know how

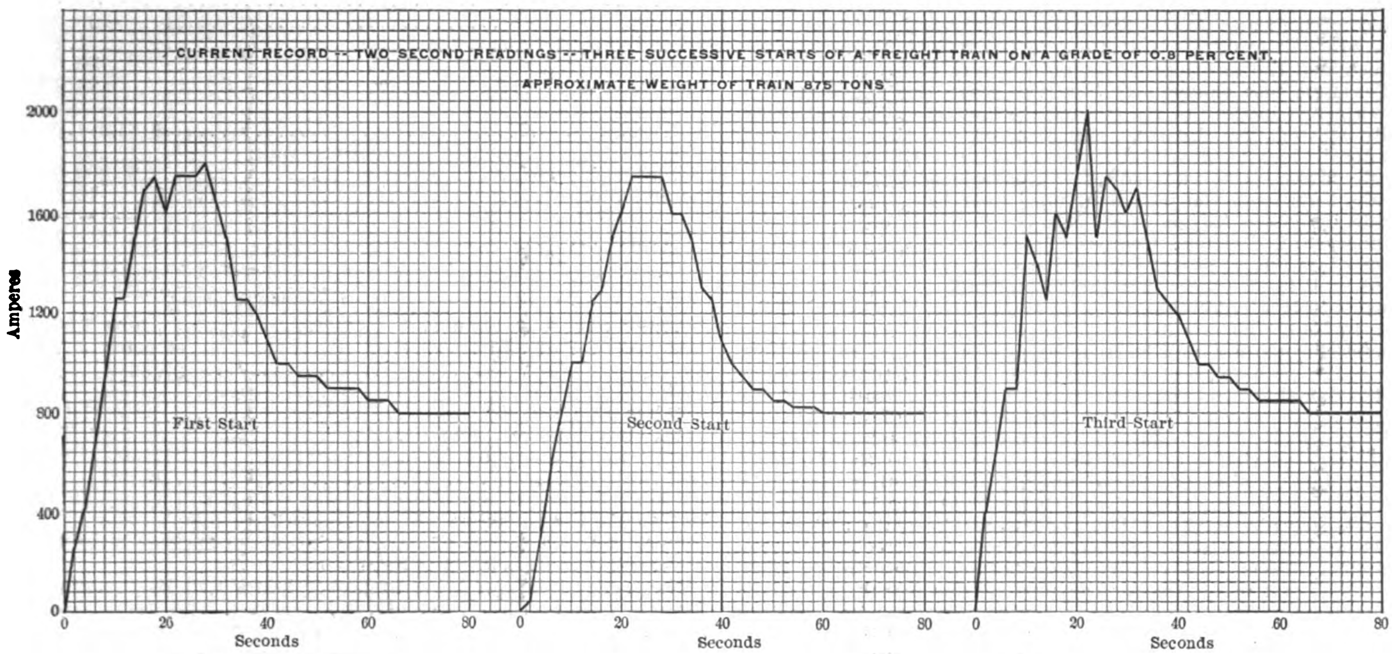


FIG. 1.

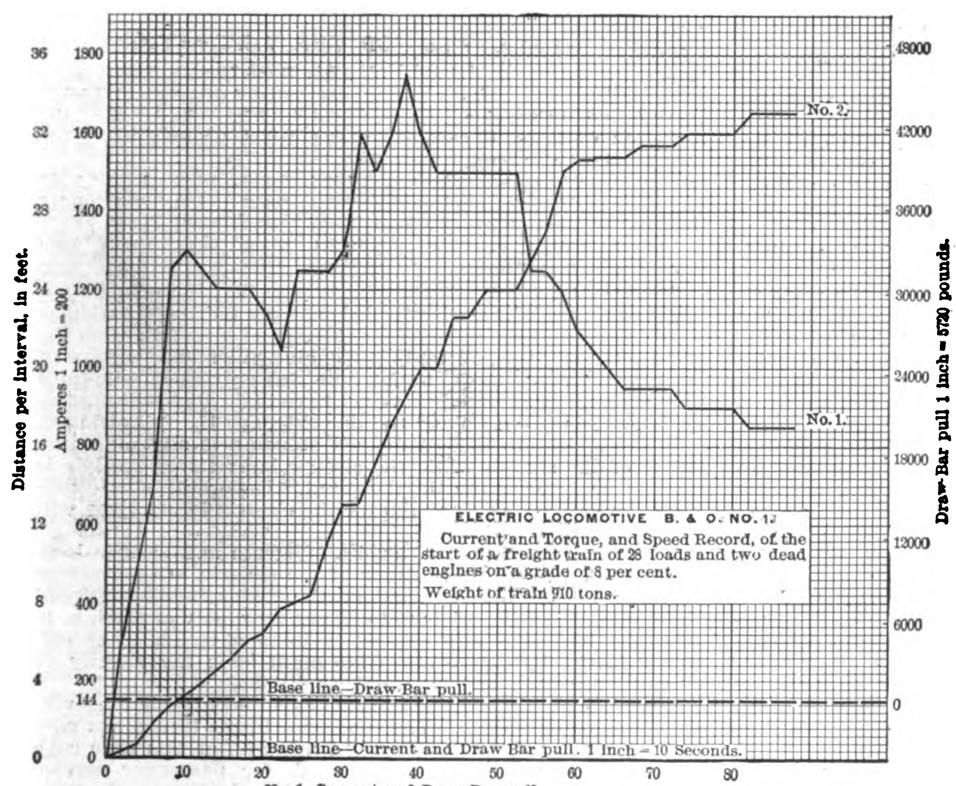
we determined the drawbar pull exerted for each ampere of current put into the locomotive. The Pennsylvania Railroad Company's dynamometer car was secured and coupled in between the electric locomotive and a train of known weight.

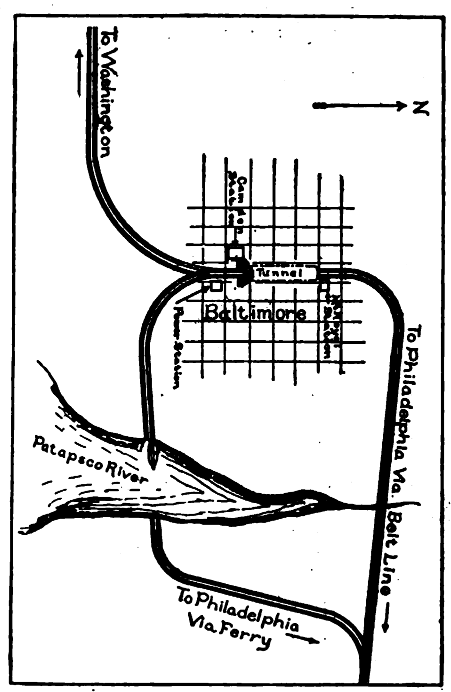


No. 1. Current and Draw-Bar pull.
No. 2. Acceleration—feet per interval of two seconds.

FIG. 2.

The weight of each car in pounds had been accurately determined beforehand. The regular two-mile haul up grade was then made. When the train was in the tunnel on the grade the pull was uniform, as was shown in the diagrams taken on the dynamometer car.

When no drawbar pull was recorded the pen rested on base line No. 1. The height or ordinate of the irregular curve at any point represented the drawbar pull at that instant. Measuring the same in inches and subtracting a constant and then multiplying by 4,000, gave the drawbar pull in pounds, i. e., every inch in height represented 4,000 pounds. The paper traveled under the pen at a rate proportional to that of the train. An irregular line marked No. 2, above the base line, was the planimeter record, from which was determined the



MAP OF BALTIMORE TUNNEL.

mean pull for any time. Having, then, the velocity, or the feet per minute and the mean pounds pull exerted during any period, we readily obtained the horse-power developed.

Another line on the diagram showed the chronograph record, each of the small offsets in the line occurring every five sec-

onds. For every hundred feet the train moved, the paper moved an inch. The distance in inches between any two of these offsets gave us readily the velocity of the train. Another line represented the time readings of current and voltage which were taken in the locomotive, a push-button in the locomotive being electrically connected with this recording apparatus. These readings were numbered, so it was easy to tell the current at any time and location. Still another line showed a record of the different stations in the tunnel. From this we determined the location of the train at any time.

The first test showed (a) how the start was made on the down grade leading to the tunnel; (b) how after the train was fully started, the drawbar pull dropped off; then (c) how it gradually increased as the train came on to the 0.8 per cent. grade in the tunnel; and (d) after the train was wholly on the grade, how even the pull was, until near the stop, when the grade increases 1.2 per cent. Mr. Dunbar, the official of the Pennsylvania Railroad Company in charge of the car, showed some diagrams of steam locomotive work under similar conditions, and it was seen that their amplitude of vibrations was considerably greater than those of the electric locomotive. This was undoubtedly due to the absence of the angle crank on the electric locomotive, and because its pull is uniform throughout the entire revolution of the armature. Most of the vibrations of the pen shown on these curves were due to vibrations of the dynamometer car which was mounted on a single truck.

From test No. 1 we obtained the total drawbar pull in pounds, and knowing the weight of the train, we found the drawbar pull to be 22. + lbs. per ton of weight. Subtracting the grade pull, which, in the case of an 0.8 per cent. grade, is sixteen pounds, we obtained 6. + lbs. per ton as the train resistance. This confirms the usual allowances made for freight train resistance. These observations were taken in September, 1895, on a very hot day. During the past winter months the train resistance has increased, due, no doubt, to greater journal friction, caused by thickened lubricants, and we find it to be from our records about 20 per cent. to 30 per cent. greater than in September.

Test No. 2 was made after we had switched off six cars. The run was made under similar conditions and the same character of observations was made. The difference in drawbar pull of the two trains would naturally be the drawbar pull necessary for the six cars switched off. We had their exact weight, and were thus again able to find what the drawbar pull per ton was. It was a check on our first figure and was very close to it, the slight difference we found being due to one brake on the six cars being partially set during the first run and unknown to any one.

We had the readings of current during the first run, also during the second. The difference of these should show the current required to haul six cars switched off. Dividing the difference in the drawbar pulls recorded in the two tests by the difference in current recorded, gives us directly the net drawbar pull in pounds per ampere of current. This was 28.6 lbs.

It will, of course, be noted that by this method we eliminated the current required to drive the locomotive. To determine how much this was, and to check our conclusions, we divided the drawbar pull in pounds recorded in the first by 28.6 and thus obtained the current that should exert that net drawbar pull. Subtracting this current from the current actually recorded on the locomotive would give the current required to drive the locomotive. We found it took 144 amperes. As a further check we figured similarly for the second test and obtained precisely the same, i. e., 144 amperes. So at any time now when hauling a train with the four motors in series if we take the current indicated on the amperemeter and subtract the 144 amperes needed for the locomotive, and multiply the remainder by 28.6, we have the total net drawbar pull in pounds, and if we divide this by the drawbar pull per ton we get the tons of load we are pulling.

From the results obtained above we were able to show the current and drawbar pull at any moment while accelerating a train. The curves (Figs. 1 and 2) explain themselves very fully.

The acceleration curve, (Fig. 2), was obtained by dropping doughballs every two seconds, and they were the markers used in determining the distances traveled in each interval, as shown on the curves in Fig. 2.

When it comes to a comparison of the economy of electric and steam locomotives it is readily seen that it is a difficult undertaking, knowing as we do the figures of only a single isolated electric plant operating under special conditions and for a comparatively short time. One great incidental advantage of electric locomotives in tunnel service is that they are smokeless. This is an important hygienic consideration, but one which can hardly be computed in dollars and cents. But it may be of general interest to know how the actual operating expenses per engine mile of the electric locomotives during October, 1895, compare with those of a prominent and large Eastern railway for the same month.

For the operation of the Baltimore and Ohio tunnel power house for the month of October, 1895, the itemized expenses were as follows:

Labor	$1,345.70
Coal ($1.35 per ton)	400.96
Oil and waste	151.26
Water	50.66
Maintenance	25.42
Total	$1,974.00

The expense of electric locomotives was:

Motor engineers	$ 200.00
Oil and waste	12.16
Total	$ 212.16
Total expense	$2,186.16

There were hauled through the tunnel 353 trains

Average weight of train	tons	1,095
Average time of trip	minutes	20
Average current	amperes	986
Distance of trip	miles	4
Total engine travel	miles	1,412
Total engine travel "idle"	miles	3,756
Actual time consumed for above service	hours	118
Idle time for month	hours	626

It is customary to consider an engine with steam up as equivalent to six engine miles for each hour it is idle, so that, for comparison, the actual mileage made by the engines must be increased $6 \times 626 = 3,756$ miles.

The large charge of labor at power house will be the same for one, two, or three locomotives in service. The items, coal, water, and maintenance, and the expense on locomotives, increase with the number of locomotives in service. If we assume this increase to be proportional, the total expense and cost per engine mile are as follows:

	Total Cost.	En. miles.	Cost per en. mile.
For one locomotive	$2,186.16	5,168	$.423
For two locomotives	2,875.36	10,336	.278
For three locomotives	3,564.56	15,504	.23

The steam railway records referred to above are for October, 1895, and may be briefly abstracted as follows:

Steam Locomotive Performance.

	East div.	West div.	Cen. div.	N.&W. div.	Entire Line.
Locomotives in service	74	57	33	28	192
Av. engine mileage in service	2,834	2,966	2,293	2,305	2,703
Average cost per engine mile—					
Passenger engines	.1926	.1666	.1629	.1552	.1765
Freight engines	.2472	.2656	.3428	.2303	.2615
Switching engines	.1489	.1659	.1828	.1425	.1577
Work engines	.2391	.2258	.2617	.2169	.2351
Total engines	.2080	.2183	.2121	.1797	.2095

From the figures given above it is seen that the actual operating expenses of the electric locomotives for that particular month are about the same as for the freight locomotives on the steam railroad, i. e., 23 cents per engine mile. The service of the electric locomotives at that time was only about one-third that which it is expected they will have to do when the passenger service is taken up and the line extended the full distance.

As originally intended, a method of using to advantage the power of the station while the electric locomotives are idle is soon to be incorporated in the plant. Under the new conditions the cost per engine mile for the electric locomotives will be far under that of steam.

A comparison of the efficiencies of steam and electric locomotives shows slightly in favor of the electric. Observations made on French railways and on the Pennsylvania Railroad show that about 45 per cent., to 55 per cent. only of the i. h. p. of steam locomotives is applied to hauling trains. The efficiency of the Baltimore and Ohio plant is in the vicinity of 60 to 65 per cent. under normal conditions.

A word may be added as to our experience with the overhead conductor system. The conductor in the tunnel has now been in position for nine months. During all of this time coke burning locomotives have been used, for passenger service with the consequent presence of a good deal of gas and vapor. For the first six months about half of the conductor was constantly wet from the drip due to leaks in the masonry. This occasioned a muddy, slimy deposit over the insulators and a considerable portion of the conductor. The porcelain insulators are almost entirely obscured in some places by this deposit and that of small particles of carbon given by the locomotives.

Current was first turned on the line about three months after the tunnel structure was erected. The leak to earth was at first twenty-one amperes, but in a day or two this dropped to about four amperes—the present leakage. The inside of the conductor was coated with a combined deposit of rust and muddy sediment. Heavy currents were taken from it by the contact shoe only with difficulty and the presence of much arcing, heating and showers of sparks. It was found impracticable to run on this surface. By applications of kerosene and frequent scraping with special shoes, a direct contact of the trolley shoe with the conductor was made possible. Although a single contact shoe then worked with little or no sparking, two shoes in tandem were adopted. Their operation through the conductor is smoother, and the contact over muddy portions of it is more nearly positive. At intervals of about three weeks the conductor is treated with kerosene, and brushing shoes are run through it, about one or two trips with these brushing shoes being all that is necessary. This serves to prevent the further accumulation of rust and to remove the sediment from the contact surfaces An inspection shows a smooth surface over which the shoes run. Contact with the metal is seen to be in high spots and thin lines which are slowly increasing in extent.

No considerable sparking now occurs, except at the wet places, where it is occasioned by the presence of water and sediment. With the exception of three places, about 200 feet long, each, the conductor is at present dry.

The bolts to the arch of the tunnel are both galvanized and painted. They show no signs of rusting. The painting has, in general, protected the surface of the conductor and channels. The sides and top of the inside of the conductor are coated with rust. Most of this is hard and close grained, some of it, however, flaky. In no case is there apparent a reduction of thickness of any of the ironwork, due to rusting. Outside the tunnels the conductor is in uniformly good condition. It adapts itself to changes of temperature without trouble. The inside of the conductor is coated with rust, but in no case has there been any trouble from it. The deposit appears to be very light. There was at no time any sparking between contact shoes and conductor outside of the tunnel.

SOCIETY AND CLUB NOTES.

PHILADELPHIA ELECTRICAL TRADES ASSOCIATION.

At a meeting of the Executive Committee of the Electrical Trades Association, a committee composed of Mr. C. E. Trump, of the Novelty Electric Company; Mr. C. M. Wilkins, of Partrick & Carter Company, and Mr. A. Bournonville, of Alfred F. Moore, was appointed to confer with some of the New York houses, with a view to interesting them on the subject of mutual protection against delinquent customers. It is proposed to hold such a meeting at the Astor House on March 4.

The object of the Electrical Trades Association is to give to the various members, timely notice of such current purchasers as are becoming delinquent. Incidentally the officers have already found that it is also an assistance as a moral force in collecting outstanding accounts from honest debtors, and at the same time it gives protection against dishonest debtors. The association is chartered and has acted under eminent legal advice throughout. It is based on an association which has been in existence in the plumbing trade for several years very successfully. Realizing the benefit it has been in Philadelphia the association is desirous of co-operation with New York, Boston, Chicago and other large centers. Its membership already comprises concerns in the states of New York, Pennsylvania, New Jersey and Maryland.

THE NEW YORK ELECTRICAL SOCIETY AT THE EDISON ELM STREET STATION..

A most interesting and successful meeting of the New York Electrical Society was held at the Elm street station of the Edison Electric Illuminating Company of New York on Feb. 27. The attendance was large and representative. The chair was taken by Dr. Laudy, vice president, and a paper was read from the president, Mr. John W. Lieb, who was unfortunately kept at home by sickness. The subject matter was, however, admirably presented by Mr. A. Williams, with the aid of numerous charts. Mr. R. R. Bowker also supplemented the paper by an address of beautiful clearness and simplicity on a number of technical and commercial points connected with the local Edison system and its management. After well-deserved votes of thanks, the visitors were escorted through the station by guides, in parties of about a dozen, and were then entertained with refreshments in Mr. Bowker's reception room. Altogether, the evening was one of the most delightful and instructive character imaginable.

NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION.

Mr. C. O. Baker, Jr., master of transportation, has issued the following notice:

The Trunk Line Association have granted a rate of a fare and one-third for the round trip from points in their territory to delegates attending the nineteenth convention of the National Electric Light Association, to be held in this city May 5, 6 and 7, 1896.

The convention will be held in a hall most admirably adapted for the purpose—in the Industrial Building, Forty-third street and Lexigton avenue, during the progress of the great electrical exposition.

NEW ENGLAND ELECTRICAL TRADE ASSOCIATION.

Representatives from a number of electrical firms met last week at Young's Hotel, Boston, and formed the New England Electrical Trade Association, for protection against bad debts and to establish a bureau of credit. These officers were chosen temporarily: President, Frank Ridlon; Vice-president, P. M. Reynolds; Treasurer, D. A. Andrews, Jr.; Executive Committee, D. A. Andrews, Jr., Chairman; P. M. Reynolds, Arthur Drew, H. B. Cram, and C. C. Allen.

The firms represented were the Pettingell-Andrews Company, Bibber, White & Co., Anchor Electric Company, Frank Ridlon Company, Boston Electric Company, Electric Gas Lighting Company, Wheeler Reflector Company, J. W. Poole, Bernstein Electric Company, and the New England Electric Supply Company.

The annual meeting for the election of officers will probably be held on the third Friday of March, at Young's Hotel.

THE ELECTRICAL ASSOCIATION OF BROOKLYN.

A meeting was held at 17 Whipple street, Brooklyn, Feb. 28, to complete the organization of the society of electricians, recently mentioned in these columns.

The meeting having been called to order, Mr. G. H. Wood was elected temporary chairman and M. R. Rodrigues acted as secretary.

The name decided upon was "The Electrical Association of Brooklyn."

The objects of the association will be the promotion and study of the arts and sciences connected with the electrical and allied industries and the welfare of those interested in the same, also the maintenance of rooms and procurement of apparatus and literature for their use.

The association will consist of associate and active members. Associate members will be those who are or have been connected with the electrical or allied industries; active members being those who possess a thorough knowledge of the electrical science.

The following were appointed to select rooms and also to act as a committee on membership: Messrs. G. H. Wood, of the Brooklyn Edison Illuminating Company; A Davidson, of the Commercial Cable Company; C. R. Underhill, of the Western Electric Company; H. Cramer, Brooklyn Edison Illuminating Company; H. E. Wadsworth, Tucker Construction Company.

Any further information regarding the association will be furnished by addressing the secretary, M. R. Rodrigues, 17 Whipple street, Brooklyn.

The next meeting of the association will be held at the Edison Building, Pearl street, Brooklyn, on Thursday evening, March 5. Practical men interested are invited to be present.

MARRIED.

CHAMBERLAIN—BRUERE.

Mr. Rufus Nutting Chamberlain, of this city, was married on Feb. 15 to Miss Marie Louise, daughter of Mr. Charles Meirs Bruere, of Cream Ridge, N. J. The happy pair, who are now on their wedding trip, have the congratulations of a host of friends. Mr. Chamberlain was recently in charge of the electric fleet at the Atlanta Exposition, and is well remembered for his successful work as electrical engineer of the big fleet at the Chicago World's Fair.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED FEB. 25, 1896.

Alarms and Signals:—

ELECTRIC ANNUNCIATOR. J. Kips, Yonkers, N. Y., 555,101. Filed Jan. 8, 1895.
Obviates the use of an electromagnet in the construction and operation of annunciators.

ELECTRICAL ANNUNCIATOR. F. Porath, Appleton, Wis., 555,120. Filed July 6, 1895.
An annunciator by means of which an alarm will be sounded when the water in a boiler rises above or falls below a certain level.

ELECTRIC CALL AND ALARM APPARATUS. J. P. Hartfuss, Merzig, and E. Herz, Saarbruck, Germany, 555,160. Filed Feb. 14, 1895.
Details of a system whereby an alarm may be sounded simultaneously in several stations, and means for answering the same.

ELECTRIC RAILWAY SIGNAL SYSTEM. J. Irwin, Omaha, Neb., 555,167. Filed Feb. 18, 1895.
Consists of two rotatory disks, with magnets for operating them.

FIRE AND BURGLAR ALARM. R. L. Levin, Menominee, Mich., 555,173. Filed May 25, 1895.
An electric switch arranged in proximal relation to a trip lever, and an arm attached to a pivoted switch arm and arranged in the path of the trip lever, so as to be operated thereby.

ELECTRIC SIGNALING DEVICE FOR RAILROADS. G. A. Lyncker, Munich, Germany, 555,217. Filed April 27, 1895.
Transmits a signal over the whole stretch up to the office of the next station when a train leaves a station and a signal is made at the same time at the station it started from.

Primary Batteries:—

PRIMARY BATTERY. W. A. Crowdus, Chicago, Ill., 555,303. Filed June 12, 1895.
Consists in the method of connecting the cells in series with one another.

PRIMARY BATTERY. W. A. Crowdus, Chicago, Ill., 555,304. Filed Oct. 4, 1895.
A negative element consisting of a reticulated supporting conducting plate, provided with a porous coating of baked copper oxide and a carbonized binder.

Distribution:—

ELECTRIC TRANSFORMER. W. Carter, Louisville, Ky., 555,074. Filed April 23, 1895.
Employs a primary and secondary coil and a core, the latter being of the open iron type, and consisting of a plurality of approximately horseshoe-shaped laminae of iron.

ELECTRIC LIGHTING SYSTEM. S. L. Trippe, New York, 555,192. Filed June 21, 1893.
A transferring device for changing the current from one circuit to another, and a series of shunts for neutralizing the induced current.

ELECTRIC DISTRIBUTION SYSTEM. E. C. Myrick, Providence, R. I., 555,326. Filed May 23, 1893.
Announces at any desired point when a fuse has burned out and indicates the location of the fuse box in which a fuse has thus burned out.

CONSTANT POTENTIAL ALTERNATING GENERATOR. W. K. Freeman, Fort Wayne, Ind., 555,152. Filed July 5, 1895.
The combination with a system of generator regulation embodying a pulsating current generator, a transformer having its primary in series with the working circuit of the generator, and its secondary controlling the energizing of the field of force, of a current regulator controlled by the speed of rotation of the main drive shaft interposed in said secondary circuit of the transformer, whereby the energy of the field of force is governed in accordance with both the rate of rotation of the drive shaft and the consumption of energy in the working circuit.

ALTERNATING MOTOR. N. Tesla, New York, 555,190. Filed May 15, 1888.
The combination of energizing circuits, one adapted to be connected with a source of alternating current, the other arranged in inductive relation to the said first circuit, whereby the motor will be operated by the resultant action of the two circuits.

ELECTRIC MOTOR. E. Thomson, Swampscott, Mass., 555,191. Filed Dec. 19, 1890.
The combination, in an electric motor, of a divided armature-core, two field magnets acting respectively upon the two parts of the divided armature, and means for varying or changing the relative effects of said field magnets, in proper manner to restore the speed to normal.

ARMATURE WINDING. W. H. Knight, Schenectady, N. Y., 555,216. Filed April 13, 1895.
An armature coil composed of a six-sided figure, the two halves of which lie in different but parallel planes, and are united by a portion approximately radial to the circumference of the armature-core.

BRUSH FOR DYNAMO ELECTRIC MACHINES AND MOTORS. F. W. Kreinberg, Elsey, Germany, 555,381. Filed Feb. 17, 1894.
A brush formed of a bundle of fine wires braided together and saturated with a lubricant, and a casing inclosing the wires and lubricant.

Lamps and Appurtenances:—

HANGER BOARD FOR ARC LAMPS. A. J. Oehring, Chicago, Ill., 555,112. Filed Sept. 18, 1894
An insulating non-inflammable hanger board that can not be readily broken, and an improved switch and improved binding posts for the hanger board.

ELECTRIC LAMP FOR VEHICLES. W. A. Crowdus, Chicago, Ill., 555,305. Filed Oct. 4, 1895.
Relates especially to the construction of the reflector portion and means for holding it in position.

HANGER FOR SIGNAL LANTERNS. E. R. Knowles, Middletown, Conn., 555,320. Filed Dec. 5, 1893.
Provides means enabling the lanterns to always hang vertically.

Measurement:—

ELECTRICAL MEASURING INSTRUMENT. F. von Hefner-Alteneck and H. Görges, Berlin, Germany, 555,286. Filed Nov. 25, 1895.
A solenoid instrument.

Miscellaneous:—

ELECTRIC VISUAL INDICATOR. F. W. Cole, Newton and W. M. Chapman, Needham, Mass., 555,076. Filed June 3, 1892.
The indicating surfaces or drums are actuated by springs or equivalents, and let-offs are provided for them which are operated simultaneously by an electromagnet.

SECONDARY ELECTRIC CLOCK. F. L. Gregory, Chicago, Ill., 555,090. Filed May 11, 1895.
An electro-mechanical clock system, embodying an electro-mechanical secondary clock, having actuating apparatus in circuit with the primary clock.

SCENIC THEATER APPARATUS FOR PRODUCING SUN EFFECTS. A. J. Oehring and A. L. Tucker, Chicago, Ill., 555,113. Filed May 13, 1895.
The combination, with a rotating pivoted arm, of the lamps carried on the end thereof, a screen, a traveling carriage, the lamps carried thereon, a pivoted arm, the lamps carried on the end thereof, and a screen.

CIRCUIT CONTROLLING APPARATUS FOR SCENIC THEATERS. A. J. Oehring and A. L. Tucker, Chicago, Ill., 555,114. Filed May 13, 1895.
Automatically actuated devices for controlling the circuits through the several series of translating devices employed in lighting and otherwise producing the scenic effects.

ELECTRIC WELDING INDICATOR. E. Thomson, Lynn, Mass., 555,130. Filed July 23, 1888.
An electric transformer, a counter secured to the secondary bar or circuit of such transformer, and means for actuating or controlling such counter by the current flowing in the bar.

ELECTRIC RIVETING. E. Thomson, Swampscott, Mass., 555,131. Filed Oct. 20, 1890.
Consists in making the rivet in two parts, which are placed in position in the rivet hole with their ends abutting, and are then subjected to end pressure.

TOY. J. F. Prentice, Brooklyn, N. Y., 555,181. Filed July 24, 1895.
Designed to illustrate the story of "Jonah and the Whale;" magnets are employed.

PROCESS OF MANUFACTURING WHITE LEAD BY ELECTROLYSIS. A. B. Browne, Cambridge, and E. D. Chaplin, Natick, Mass., 555,232. Filed July 2, 1894.

ELECTRICAL PROPULSION OF VESSELS. E. A. Le Sueur, Ottawa, Canada, 555,252. Filed March 26, 1894.
Consists in means by which an electrical conductor may be secured underneath the surface of the water.

ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 555,259. Filed May 31, 1895.
Constructed in such a manner that there shall be a circulating air space between the double walls.

ELECTRIC CLOCK. S. Fischer, Brooklyn, N. Y., 555,313. Filed May 10, 1895.
Consists of an electric clock, in which the pendulum is driven by electric impulses imparted to it, as from a primary battery, so as to operate a going train and a striking train.

ELECTRIC RECEPTACLE FOR FLASHING POWDER IN FLASH LIGHT BURNERS. H. E. Rathbun and F. Berby, Pawtucket, R. I., 555,332. Filed Jan. 7, 1895.
A blank cartridge for photographic purposes, provided in itself with an electric wire adapted to ignite a charge of flashing powder placed in the cartridge.

MACHINE FOR CONNECTING ELECTRIC CONDUCTORS. H. J. Savory, Somerville, Mass., 555,403. Filed April 17, 1893.
A machine for connecting a small electric conductor to a larger one, a frame, a clamping device to clamp and rigidly hold the smaller conductor and an upsetting device to upset the smaller conductor within a perforation in the large.

PROCESS OF AND APPARATUS FOR ELECTROLYTICALLY FORMING TUBULAR BODIES. I. Klein, Buda-Pesth, Austria-Hungary, 555,452. Filed Dec. 7, 1894.
Relates to the rolling of metallic deposits precipitated by galvanic process, its object being to compress and mold such metal.

Railways and Appliances:—

ELECTRIC CAR LIGHTING APPARATUS. W. Biddle, Brooklyn, N. Y., 555,068. Filed Dec. 24, 1894.
The combination with the field magnets and armature in a dynamo of a magnetic intercepter and means for moving the same endwise of the armature in proportion to the speed of the armature to intercept the lines of magnetism as the speed of the armature is increased or the reverse.

TROLLEY WHEEL SWITCH. P. A. Williams, Decatur, Ill., 555,145. Filed June 10, 1895.
Comprises a plate having grooves in its under surface extending from each side of the main wire to the corresponding side of each switch wire.

CONDUIT ELECTRIC RAILWAY. C. M. Bridges, Seattle, Wash., 555,208. Filed May 31, 1895.
Consists in the novel construction and arrangement of parts.

ELECTRIC RAILWAY. W. H. Jordan, Brooklyn, N. Y., 555,248. Filed Jan. 17, 1896.
Provides a simple system and apparatus for signaling on electric railways.

CONTACT DEVICE FOR ELECTRICALLY PROPELLED VEHICLES. E. B. W. Reichel, Gross-Lichterfelde, Germany, 555,263. Filed Aug. 15, 1895.
The combination with a horizontally extending fractional contact device, of a central revoluble contact.

UNDERGROUND CONDUCTOR SYSTEM FOR ELECTRIC RAILWAYS. C. T. H. Schwieger, Berlin, Germany, 555,266. Filed Nov. 15, 1895.
Relates to sectional conductor systems.

ELECTRIC MOTOR FOR STREET CARS. H. M. Neer, Springfield, O., 555,392. Filed April 25, 1895.
The combination with an outer casing and an inner supporting frame, track wheels having stub axles extending through said casing, and a motor supported on said frame, universal joints between said stub axles and motor shaft, and springs between said casing and axles.

ILLUMINATED SIGN FOR ELECTRICALLY DRIVEN STREET CARS. R. H. Engle, Garden Lake, N. J., 555,440. Filed March 8, 1895.
A casing having in one or more of its sides a transparent or translucent sign plate, an electric lamp projecting longitudinally into said casing from either end of the same.

SECTIONAL CONDUCTOR FOR ELECTRIC RAILWAYS. W. H. Baker, Pawtucket, R. I., 555,470. Filed March 21, 1895.
Consists in dividing the said conductor in sections, each normally disconnected from and auxiliary to the main conductor or feed-wire.

Regulation:—

ELECTRIC ELEVATOR CONTROLLER. E. P. Warner, Chicago, Ill., 555,136. Filed Oct. 29, 1892.
An arrangement of cams and cam guides for operating a reversing switch and a variable rheostat.

SYSTEM OF CONTROL FOR ELECTRIC MOTORS. E. A. Sperry, Cleveland, O., 555,291. Filed Feb. 16, 1895.
Consists in devices for automatically varying the magnetization of the field.

REGULATING ELECTRIC DISTRIBUTION SYSTEM. J. Burke, Schenectady, N. Y., 555,301. Filed Dec. 24, 1894.
Consists in supplying the circuit with current from main sources of supply of different potential and regulating the potential of the supplied current by intermediate variable sources of electro-motive force.

Telegraphs:—

TELEGRAPHIC REPEATER. L. Horton, Jr., Reading, Pa., 555,-165. Filed Dec. 14, 1895.
Certain modifications in the construction and mutual relations of the parts of the apparatus heretofore generally employed for this purpose.

Telephones:—

SHORT DISTANCE TELEPHONE COMMUNICATION. W. L. Bradshaw, Cincinnati, O., 555,073. Filed Sept. 28, 1895.
A novel means for short circuiting the receiver, whereby low resistance bell-circuit is made either way from said receiver.

TELEPHONE TRANSMITTER. A. Graham, London, England, 555,-154. Filed May 3, 1894.
A telephone transmitter of the Hunning type.

RAILWAY TELEPHONE SYSTEM. W. H. Nixon, Providence, R. I., 555,222. Filed Jan. 28, 1895.
Means for connecting a portable telephone with telephones at the ends of the line.

TELEPHONE. M. Garl, Akron, O., 555,239. Filed April 4, 1895.
The combination of a helical L-shaped spring, having attached to the free horizontal portion of said spring a diaphragm, said diaphragm being free to vibrate with the spring, an electrode and a receiver.

PATENTS ISSUED FEB. 18, 1896.

MEANS FOR SUPPORTING AND INSULATING ELECTRIC CONDUCTORS. T. T. Eckert, New York, 554,664. Filed Dec. 8, 1894.
The combination of a glass hood having an interior screw thread; an iron pin and a wooden thimble.

ELECTRIC DOOR OPERATING APPARATUS. O. H. Hicks, Chicago, Ill., 554,818. Filed Aug. 24, 1893.
Gives details of construction of mechanism actuated by electromagnets in circuit with primary batteries, for opening and closing doors.

ELECTRIC DOOR OPERATING APPARATUS. O. H. Hicks and R. F. Troy, Chicago, Ill., 554,819. Filed Aug. 8, 1895.
Similar to above.

ACTUATING MECHANISM FOR ADVERTISING DEVICES. M. M. Gillam, New York, 554,926. Filed Oct. 15, 1895.
A rotatable sign, a shaft carried by the sign, a disk secured to said shaft and electromagnet, an armature therefor, a circuit making and breaking device for energizing and de-energizing said magnet, consisting of a flexible contact strip and a lever arm traversing the same carried by the armature and mechanism controlled by said lever arm for rotating said disk.

SWITCH AND SIGNAL APPARATUS. E. H. Goodman and S. H. Stupakoff, Pittsburg, Pa., 554,927. Filed Oct. 17, 1895.
A disk provided with a notch and adapted to be operated by the signal mechanism, and two notched disks adapted to be operated, one by the switch mechanism and the other by the switch rails, the signal disk and the switch disks being so mounted as to intersect.

LEGAL NOTES.

A SUIT TO OPEN TELEPHONE LINES TO COMPETITOR.

NORWALK TELEPHONE CO. VS CENTRAL UNION AND OHIO TELEPHONE CO,

The Norwalk (Ohio) Telephone Company has just filed a petition to compel the opening of the lines of the Central Union Telephone Company by mandamus, under the common carrier law, which governs telegraph, telephone and kindred services. The Norwalk company is the new opposition local company, using the Harrison system, and desires to have the old exchange not only connect with the new, but transmit messages from its patrons to points on the Central lines outside Norwalk. The question thus raised is highly important. Mr. C. H. Gallup is the president of the Norwalk Telephone Company, which is represented by Messrs. C. P. and L. W. Wickham.

The Central Union Telephone people do not appear to have made any move yet in the matter.

ELECTRIC SWITCHES—VICTORY FOR THE BRYANT ELECTRIC CO.

Judge Townsend in the United States Circuit Court, at New Haven, Conn., has handed down a decision dismissing the bill in the suit for infringement of patent brought by O. S. Platt, against the Bryant Electric Company. The article in dispute was an electric switch which the company have been making in large quantities.

Several years ago Mr. Platt invented a switch for use on electric lights. He secured a patent on it, but it was not manufactured to any great extent at that time. In the meantime the Bryant Company obtained a switch which was somewhat similar. Mr. Platt afterwards learned that they were manufacturing what he believed was his invention and he instituted proceedings to test their right.

The Bryant Company denied that there was any infringement. They claimed that it was merely another application of old ideas. This view of the patent, it would seem, has been sustained by the Circuit Court, although the full text of the decision is not yet at hand.

The amount of royalty which Mr. Platt might have obtained had he won his case would no doubt have been very large, as the Bryant Company manufactured the switch in large numbers. It is possible that an appeal may be taken to the United States Supreme Court.

STREET CAR HEADLIGHT NOT NECESSARY.

In the Superior Court at Grand Rapids, Mich., Judge Burlingame instructed the jury to render a verdict of no cause of action in the case of Terrence McGee against the Consolidated Street Railway Company.

The plaintiff was crossing a street in 1892 when he was struck by an electric car and his left leg cut off. He sued for damages; showed that there was no headlight on the car and the jury rendered a verdict of $6,000 damages. The Supreme Court reversed the case and a carefully prepared opinion was handed down declaring that the plaintiff according to the facts shown was guilty of contributory negligence. No headlight was necessary, as the car was brilliantly lighted and carried colored lights according to the provisions of the city ordinance.

SUITS INVOLVING THE VAN DEPOELE TROLLEY SWITCH PATENT AND UNDERRUNNING TROLLEY.

The Thomson-Houston Electric Company (General Electric Company) has brought suit in the United States Court at New Haven, Conn., and applied for an injunction against the Kelsey Electric Specialty Company, of New Haven, and the Billings & Spencer Company, of Hartford. The complainant alleges infringement of the Van Depoele underrunning trolley patent and the suit is the outcome of the recent decision in favor of that patent.

Suits have also been brought by the Thomson-Houston Company against the Nuttall Manufacturing Company, the Simonds Manufacturing Company and the Westinghouse Company, on the Van Depoele patent, No. 424,695, Suspended Switch and Traveling Contacts for Electric Railways, and on patent No. 495,443, Suspended Switch and Traveling Contact for Electric Railways.

OBITUARY.

SAMUEL EDISON.

Samuel Edison, father of Thomas A. Edison, died on Feb. 26 at the home of his granddaughter, Mrs. W. A. Poyer, Norwalk, O., after an illness of several weeks. Mr. Edison was born in Nova Scotia ninety-one years ago last August, and in early manhood moved to Milan, Erie County, Ohio, going from that place to Fort Gratiot, now Port Huron, Mich., where he lived for more than forty years. He came to Norwalk just before the holidays, stopping there on his way to visit his famous son in New Jersey, intending later to go to the latter's winter home at Fort Myer, Fla.

Mr. Edison's parents came to the United States from Holland long before the Revolution, settling in New Jersey. Members of the family became prominent bankers during the Revolution. Some of their names appear on the Continental money of that time. Some members of the family were Tories, and after the war of independence emigrated to Canada.

When quite young Samuel Edison's father sent him to school at Hamilton, O. Then he learned the tailor's trade. He subsequently sailed for three years on Lake Erie. He was married in 1828. In 1838 he moved to Milan, Erie County, four miles from Norwalk, where Thomas A. Edison was born in 1847, the youngest of seven. Mr. Edison was over six feet tall and strong. His wife, who died several years ago, was buried at Port Huron. Mr. Edison's body will be taken there for burial. The house where Thomas was born is still standing in Milan, in good preservation.

PERSONAL.

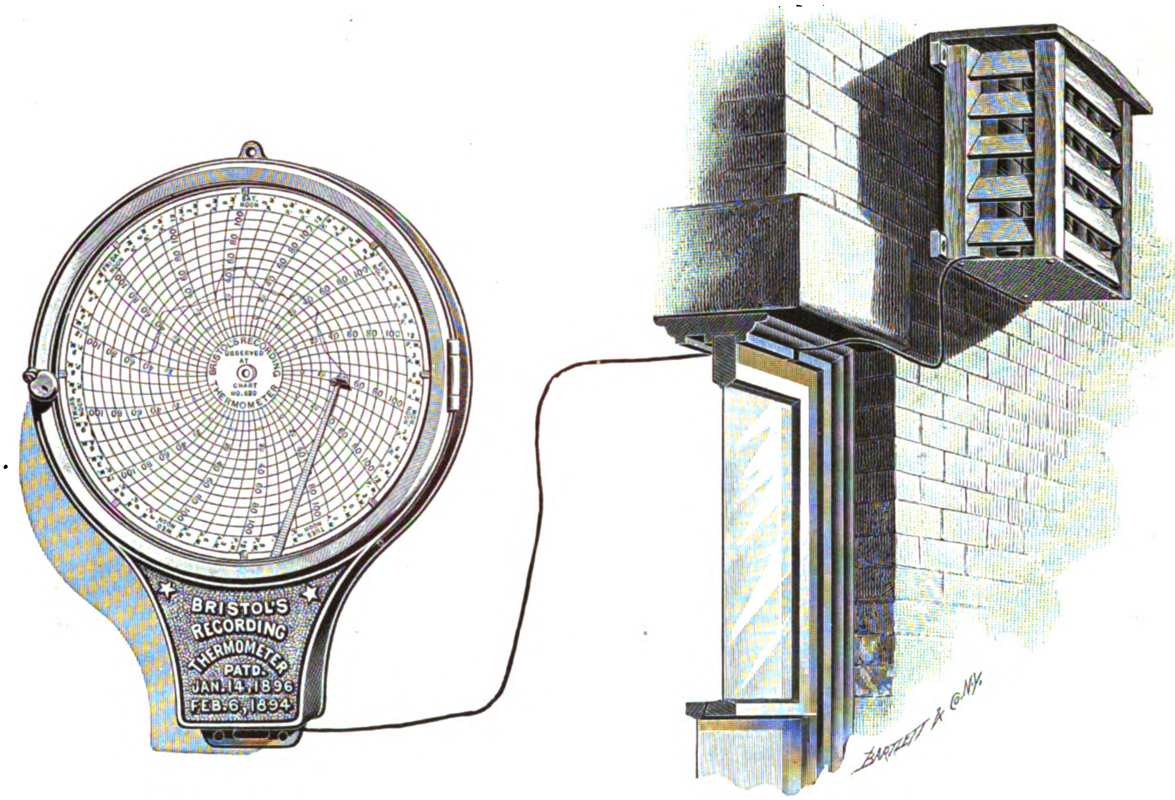
MR. F. A. LaROCHE has gone to Palm Beach, Fla., for the remainder of the winter.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE BRISTOL RECORDING THERMOMETER FOR ATMOSPHERIC RANGES OF TEMPERATURE.

The novel and especially valuable feature of the recording thermometer, illustrated in the accompanying engravings, is that the recording portion may be located at a distance of twenty-five or thirty feet from the point at which the temperature is to be measured. This makes it possible to obtain a continuous record of the outside temperature while the recorder is located at a convenient point within doors, where it may be readily observed, and its mechanism is not exposed to the detrimental influences of inclement weather. For cold storage plants, where closed rooms are to be maintained at a constant temperature for the preservation of meats, fruits and vegetables, an instrument of this kind is of great value, as the temperature may be observed without opening the doors.



FIGS. 1 AND 2.—THE BRISTOL RECORDING THERMOMETER.

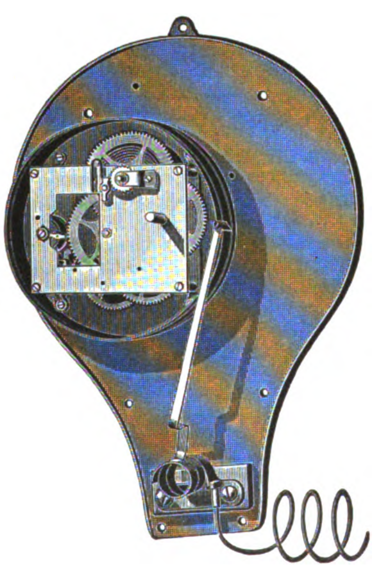


FIG 3.—THE BRISTOL RECORDING THERMOMETER.

The recording part, Fig. 1, is an application of one of Bristol's recording pressure gauges. Fig. 3 shows an interior view of the recorder, which consists of a pen arm directly attached to the free end of a tube of flattened cross-section bent into helical form. The bulb portion, Fig. 2, is placed at the point where temperature is to be measured. It consists of a series of helical tubes constructed on the same principle as that in the recorder. The helical coils are suspended in a vertical position with their lower ends free, the upper ends opening into the capillary tube connecting them with the recorder.

The system of helical tubes forming the bulb portion, the pressure tube of the recorder and the capillary connecting tube are completely filled with alcohol under pressure and permanently sealed. As the temperature rises and falls where the bulb is located, there is a corresponding expansion or contraction of the alcohol which is communicated to the recorder and registered on a seven-day chart graduated to read in degrees Fahr. Excessive pressures due to increased volume of the non-compressible liquid are provided against by the expansible form of the system of helical tubes of which the bulb is constructed.

The total volume of the bulb portion is very large, as compared with that in the pressure recorder, thus avoiding the necessity of compensating for ordinary changes of temperature in the room where the recorder is located. No correction is required for barometric changes, as only high ranges of pressure are employed.

This thermometer is being manufactured and placed on the market by the Bristol Company, of Waterbury, Conn. At 121 Liberty street, the New York branch of the company, one of the instruments may be seen in operation recording the outside temperature. The recorder is placed in the show window where it may be observed from the street.

DARLING, BROWN & SHARPES' RULES.

Under the title of "Rules," Darling, Brown & Sharpe, Providence, R. I., have published a description of their varieties of steel rules. The firm, which was originated in 1850, by Joseph R. Brown, has since that time made a specialty of the manufacture of steel rules and other instruments of precision. Since 1866 the business has been carried on under its present title. The catalogue now published treats of rules only, and embraces all forms of both standard or soft rules, and tempered rules.

BIMETALLIC WIRE.

For nearly all outdoor purposes electrical conductors are required to possess two properties, and upon these depends largely the usefulness of the conductor. These properties are conductivity and tensile strength, and whether it be in the field of telegraphy and telephony or in current transmission for light or power the same rule holds. The high conductivity of copper has made this the metal sine qua non for heavy current transmission, while the telegraph and telephone services have long since adopted and are constantly increasing their use of copper. But, unfortunately, the high conductivity of copper is accompanied by low tensile strength as compared with iron or steel, and the latter, on the other hand, are of low conductivity.

Iron or steel wire, for example, possesses about one-fifth the conductivity of copper wire. To obtain the required conductivity for ordinary uses an increased diameter is necessary. Again, iron is not durable as a conductor. On or near the seacoast its life is about three years; inland, about five years. Iron commences to deteriorate shortly after put into service. As the points of oxidation increase, so does the electrical resistance increase, and although an iron wire may be complete throughout its entire length for a considerable time after being put into use, yet its electrical resistance increases more and more as each day passes. Large poles are required for heavy iron wires, which, owing to the weight carried, must be placed close together, well braced and guyed. With the short life of iron wire it will be seen that the economy in an iron wire pole line is only in the first cost of the wire; in the end it may be found that iron is really more costly than copper.

Copper wires of large diameters are frequently employed to secure increased tensile strength, and even then the results sought are not obtained. As is well known, copper stretches under its own weight, and unless the slack is taken up at once, innumerable line troubles appear. Having wires of large diameters to carry, it follows that large poles are required, and as copper will not permit of great spans, the poles must be placed close together. The tension on the poles is very great, bracing and guying an absolute necessity, all of which adds to the cost of the line. Copper will not corrode like iron; it is a splendid conductor of electricity, but is lacking in mechanical strength.

To combine both electrical conductivity and mechanical strength it was some time since proposed to construct a compound wire, consisting of a steel core with copper shell. Wires of this type have been made, and a notable example of their use are a pair of lines of the Postal Telegraph Company between New York and Chicago. These lines were erected over ten years ago, and are still in use, with excellent results. These wires were made by depositing copper electrolytically on the steel core, but the cost involved was such that the product was too high-priced for general use.

We are glad to know, however, that the subject has been taken up again and is being vigorously pushed by the Bi-Metallic Transmission Company, who are placing on the market compound or bimetallic steel and copper wire of all sizes and for all classes of work.

Bimetallic wire partakes of the good qualities of both steel and copper—the tensile strength of the former and the conductivity of the latter. Bimetallic wire, like copper, will not corrode, and the steel core being protected by the copper sheathing, it will not oxidize like iron. The two metals of the wire are closely joined, or welded, together, forming a homogeneous mass, which permits of bends and twists in the same manner as wire of one metal.

Bimetallic wire has a greater tensile strength than wire of hard-drawn copper, and hence permits of longer spans. Having a greater tensile strength, it will be seen that wire of smaller diameter may be used, which, in turn, permits of lighter poles, fixtures, etc., and, by reason of great spans, the poles may be placed further apart. Having less exposed surface on wire, poles, etc., there is less resistance to storms of wind, rain and sleet, and consequently less liability to interruption of service.

Bimetallic wire is especially adapted for telephonic uses, owing to certain peculiar properties which it possesses, and which have been demonstrated by actual tests. Thus it is claimed that with a battery transmitter a single bimetallic wire, with an earth return, accomplishes practically the same result as is secured from a copper metallic circuit. The magneto telephone, commonly used as a receiver, is also claimed to act as a commercial long-distance telephone when used in connection with bimetallic wire in metallic circuit. Bimetallic wire is also said to require less insulation than wire of one metal, and, as less of the insulating material is needed between conductors of a cable, it follows that a greater number of conductors may be placed and operated therein. This, in turn, increases the capacity of ducts, reducing the expense of placing wires underground. It is not claimed that a bimetallic wire wholly obviates the induction so frequently heard on telephone lines, but it is claimed that when such wire is used the induction does not prevent nor interfere with conversation; that it will give a far more satisfactory service than can be obtained from a one-metal wire.

In the operation of certain systems of rapid telegraphy, especially those systems using both the alternating and direct currents, quick action of apparatus is essential for the successful operation thereof. The peculiar electrical effect in bimetallic wire produces the quick action needed, and, as a result, an improved service is said to be obtained.

The claims above cited are based on actual experiments, among them the following:

Eight miles of No. 22 B. & S. bimetallic wire was strung on the cross arms of the Western Union line along the Central Railroad of New Jersey from the Jersey City terminus of that road. This wire was not insulated at all, being fastened to the end of crossarms, mostly by mutual staples. The line was grounded at each end, was tested with telephone and found to work well. There was more or less induction, as this line of poles carries some of the hardest worked lines, leading from New York, including Wheatstone, and quadruplex; yet conversation could be carried on.

After the telephone tests, the line was tried for telegraphing, with 150 ohm relays at each end and six cells of ordinary gravity battery. The results were perfect. Then the number of cells was cut down until only one cell remained, and still the line worked perfectly, not as strong, of course, but with closer adjustment the work was first class. Wet weather did not affect the working of the line adversely; in fact, for telephoning it seemed to improve it if anything.

This wire withstood the wind and storms as well or better than the large copper wires on these same poles, and no storm has yet been able to bring it down, after several years.

The great drawback to the introduction of the wire has been its manufacture in this country. All these early experiments were made with foreign wire, but the John A. Roebling's Sons Company, of Trenton, N. J., took the matter up, and after an expenditure of considerable time and money have succeeded in making a wire absolutely perfect in every respect.

A bimetallic line of fifty-eight miles of No. 12 B. & S. has been erected between Jersey City and Trenton. This wire is put up in the same way as other telegraph wires, and is strung on the Western Union poles along the track of the Central Railroad of New Jersey to Elizabeth, and there is run over on to the largest pole line along the Pennsylvania Railroad to Trenton. This bimetallic wire is strung in this way to give it as severe a test for induction as possible. While there is a good deal of induction, still conversation can be carried on telephonically over this line with ease and comfort, while telegraphic messages have been sent between Jersey City and Trenton with 150 ohm relays at each end, with a single cell of dry battery, and not a dot was lost, nor was there any indication of lag.

The great conductivity, combined with strength, makes the bimetallic wire specially adapted for light and power distribution, and particularly for trolley wires, where a wire with little stretch is so desirable.

The bimetallic wire is patented to Mr. W. H. Eckert, the president of the Bi-Metallic Transmission Company, whose offices are in the Havemeyer Building, New York.

NEW METROPOLITAN TELEPHONE FACILITIES.

Owing to the large increase in the number of subscribers brought about by the adoption of the message rate system, by the Metropolitan Telephone Company, the establishment of an up-town office for the contract department has been decided on. This branch has been located at the Thirty-eighth street exchange of the company, No. 113 West, on that street. A large proportion of the new subscribers taken on lately by the company reside or do business in the upper part of the city, and it is believed that present, as well as prospective customers will welcome the new facilities, enabling them to carry on speedily and conveniently all negotiations regarding telephone service. It is worthy of note that during 1895, the Metropolitan Company, despite the terrible dullness in general business, enjoyed an increase of no less than 35 per cent. in the number of its subscribers, a growth attributable primarily, of course, to the message rate system, but due in no small degree to the intelligent and progressive work of the contract department of the company, under the management of Mr. Thomas H. Mack.

THE WESTERN ELECTRIC COMPANY are advertising the P. & S. china sockets. This is a new departure in this line, being composed entirely of china, which removes all danger of short circuiting in shell or base.

TIN SHADE FOR INCANDESCENT LAMPS.

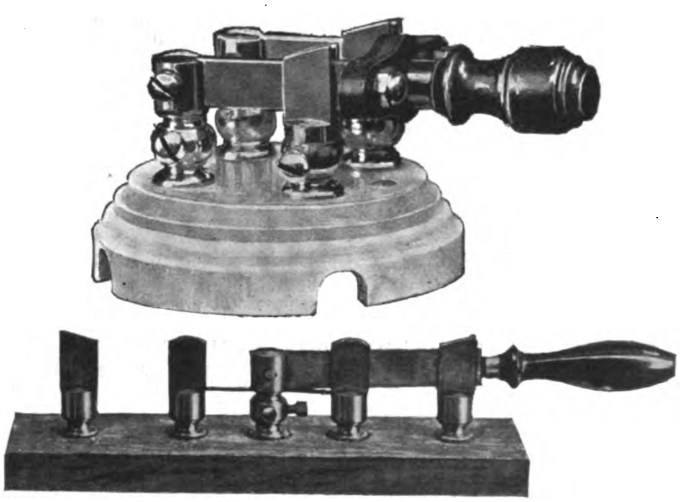
WE illustrate in the accompanying engraving the tin lamp shade manufactured by Messrs. Vallee Bros. & Co., of Philadelphia. These shades are made in two styles. Style No. 1

VALLEE BROS. & CO'S. TIN LAMP SHADE.

has an outside finish of imitation brass and the inside a bright polish. Style No. 2 has an outside finish of green paint and white enamel on the inside.

DAVIS KNIFE SWITCHES.

The Electric Railway Switch and Supply Company, of Springfield, Mass., have recently got out a very complete line of knife switches, single, double and triple pole, and single and double throw, which are meeting with favor, owing to the excellence of the workmanship, and the high grade quality of the material used. They are made in sizes from 15 amperes to



DAVIS KNIFE SWITCHES.

1,000 amperes, and are made with hard rolled copper blades, best spring copper clips, and are mounted on black polished slate or porcelain, as may be desired. This company are making a specialty at present of their "Infant" switch, as shown in the accompanying illustration, and have had a large demade for it. We show also another type.

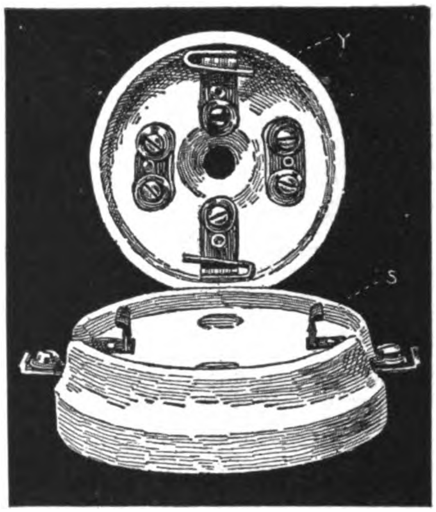
"A FEW BUILDINGS."

Under the above title the Simplex Electrical Company, of Boston, have issued a very handsome pamphlet, illustrating their work. It contains a large number of fine cuts, showing various edifices in which their wires and cables have been installed in all parts of the country. It is a very striking demonstration. Supplementary to this are a number of strong testimonials on the subect of the Simplex insulation, as well as an imposing list of buildings with the number of lights wired for. This book of good deeds was compiled by Mr. Hixson, the Western selling agent for Simplex, who has his headquarters in the Monadnock, Chicago.

THE C. D. ROSETTE.

This new rosette is manufactured by the Chapin Douglas Electric Company, 136 Liberty street, New York. Care has been taken in the general design to produce a rosette that can be quickly put up and wired, resulting in economy for the contractor.

It will be noticed that there is a yielding arm Y in the cap, and this contacts on the projecting piece in the base under the shoulder S. The open end of the arm presses against the face of the projecting piece insuring a firm contact. The cap is



THE C. & D. CEILING ROSETTE.

supported by the top of the yielding arm, resting on the shoulder S of the projecting piece, so that the rosette is not held by the contact face.

A stop pin stops the yielding arms at the right place and as they are adjustable it makes a rosette with adjustable contacts. The caps are interchangeable.

Space has been given in the location of the binding screws for the fuse links and on the base the porcelain covers the joint to protect the inside from dust and moisture. The "C. D." rosette is made in round and square base patterns.

ADVERTISERS' HINTS.

BOWERS BROS. are the headquarters in the West for Mica in its various forms. They are also agents for the Billings & Spencer drop-forge copper segments. They carry a large stock and make prompt shipments.

ANOTHER LARGE INSTALLATION of the Goubert feedwater heaters and Stratton separators has lately been made in the plant of the Portland (Me.) Electric Railways. Comment is unnecessary, as experience has shown them to be above criticism.

THE CALCULAGRAPH COMPANY have something to say about the manufacturer and the small boy, and more especially the latter's possibilities with a calculagraph. They explain how much time is saved and errors avoided.

THE ELECTRIC APPLIANCE COMPANY remind users of lamps that it is "never too early" to learn that the Packard is the best.

SEVENTY-FIVE TO 80 PER CENT. EFFICIENCY is the claim made for the Hogan boiler by its manufacturers, the Hogan Boiler Company of Middletown, N. Y. They say they are ready to substantiate this at any time.

EXPERIMENTERS WITH X-RAYS will be glad to know they may obtain Crookes tubes of any size from the Orient Electric Company, Chicago.

BRUNT & THOMPSON, East Liverpool, Ohio, are introducing a white porcelain wiring tube. It is made in lengths from two and one-half inches to three feet, affording great convenience in laying.

ELECTRIC CIVIL SERVICE EXAMINATION.

On March 6, at 10 a. m., an examination will be held for inspectors of electrical wires and appliances in the Fire Department. Persons desiring to enter this examination should apply for application blanks to the secretary of the Civil Service Board, Mr. William Briscoe, new Criminal Court Building, White and Centre streets, this city.

Department News Items will be found in advertising pages.

Electrical Engineer.

Vol. XXI. MARCH 11, 1896. No. 410.

Electric Lighting.

SCIAGRAPHIC EXPERIMENTS.

BY

W. M. Stine

IN common with many experimenters, the writer tested his collection of Crookes tube and found himself the fortunate possessor of one of the most efficient pieces of apparatus for prosecuting the new photography that is just now engaging the attention of the scientific world. It was not until February 17 that other duties permitted giving marked attention to such experiments. Believing that the more sensational features were being developed elsewhere, the investigations in the laboratories of Armour Institute of Technology were directed rather towards the character of the new radiant.

At the outset, feeling the need of some expressive term descriptive of such phenomena, the writer ventured to coin the word "sciagraphy" from two well-known Greek words. This term was first proposed in a communication to the "Western Electrician," under date of February 15, and subsequently employed in interviews given the daily press. With such explanation the term will be used in the following article.

The Crookes tube was one of the variety showing a Maltese cross on the bulb. It was excited off a Carpentier induction coil, capable of yielding an 8-inch spark, the current being obtained from a large bank of storage batteries.

Among the first points investigated was the influence of the interrupter. The coil was provided with the familiar mercury make-and-break and also a rapid interrupter. The mercurial make-and-break gave very good results, but the small interrupter was found the more reliable and seemed to shorten the time of exposure. A contact-maker, giving two interruptions to the current per revolution was also tested. This was driven by a motor and a condenser capacity of fourteen microfarads connected across the brushes. Owing to the large capacity of the condenser, a heavy current could be broken without marked sparking. The circuit breaker was tested at speeds ranging from 500 to 4,000 per minute, to note the influence on the time of exposure. The best results were obtained at the lowest speed mentioned. At high speed the admittance of the coil was too low, owing to its large time-constant. As no especial advantage could be noted when using the circuit breaker, it was abandoned for the vibrating interrupter. This point is noted in detail, since so many experimenters seem to prefer such cumbersome devices, but they are, in reality, unnecessary.

At first, many physicists seemed inclined to attribute the production of the sciagraph to the influence of ultra-violet rays, but some unpublished investigations of the writer's seem to so strongly confirm Röntgen's longitudinal vibration theory that the present tests were especially directed toward the proof or disproof of the existence of ultraviolet waves as the active agent. To this end the relative speed of dry plates towards light and the X-rays was compared. In common with other investigators, the most rapid dry plates were at first used. An exposure was then made on a slow plate, indicating no perceptible difference in the density of the negative and length of exposure. To examine the matter more critically, two plates, a rapid Seeds 27 X and a slow Carbutt B 16 plate were exposed side by side for 45 minutes. The development was completed within a few minutes, both negatives coming out with equal speed and density. The negatives were as dense and sharp as if fully exposed in bright sunlight. The test was repeated under the same conditions and with the same results. In short, we could not then, and have not since, been able to detect that the light speed of dry plates has any influence on the time of exposure to the X-rays.

These experiments were made on Feb. 18 and promptly reported, and we believe we were the first to clearly point out such facts. Since then we have preferred the use of slow plates, as they are less liable to chemical fog and give clearer shadows and sharper contrasts. This experiment of itself would seem to indicate that ultraviolet rays had nothing directly to do with the phenomena in question, since the light speed of a plate is determined by its special reference to the actinic or ultraviolet rays.

Singularly enough, the experiment also contradicts an observation made by Röntgen in his original paper. He there states the effect on the dry plate may be due to fluorescence on the plate itself established by the action of the X-rays. Were this the case, since fluorescence is of the character of transverse light waves, the sensibility of the dry plate would be the same towards the Crookes tube as light itself.

The influence of external electrodes has come in for a large share of attention in such connection. While experimenting with these, a curious phenomenon was noticed. It has been universally held that in the action of the Crookes tubes the streams of electrified particles proceed outward from the cathode alone. Mr. Perrin, in a recent communication to "Nature,"[1] has proven that both cathode and anode streams exist simultaneously. If a tube contain an object in the path of the streams, a shadow always shows opposite the cathode when the internal electrodes are connected to the coil. We found this was still the case when two external electrodes were employed. We discovered, however, that when one external and one internal electrode were connected to the coil, the shadow remained constant in position opposite the internal electrode, whether this was the positive or negative pole. Under such circumstances, the anode and cathode streams seem to be identical. The fact, if ever noted at all, has not been generally stated in the literature of the Crookes tube.

So much has been stated pro and con concerning incandescent lamp bulbs as a source of the X-rays that our results may be of interest. Many lamps of the same and of different makes were tested, and only one produced a true sciagraph, though the negative was a weak one. In this case the filament was the cathode, the anode being a piece of tinfoil pasted on the outside of the bulb. As a conclusion it may be stated that the vacuum of the ordinary incandescent lamp is too low for satisfactory sciagraphy.

A further crucial test was planned to show the character of the vibrations. The behavior of tourmaline plates towards light waves is well known. When placed in coincidence, light polarized in one plane passes freely through them, but if they be turned so that their axes are in quadrature, they practically stop out all light. It was first necessary to test the transparency of tourmaline towards the new radiant. An exposure of 45 minutes showed the plates were sufficiently transparent for the purpose. The tourmalines were clamped in position for maximum light transmission, and exposed over a plate for 90 minutes. They were then crossed to opaque position and submitted to a like exposure. Two excellent negatives were then obtained, which, upon comparison, showed the X-rays had passed through the tourmaline with equal freedom in each case. Though such a test may not be regarded as finally settling this disputed point, when taken in connection with the effect on dry plates of various sensitiveness, it reasonably proves that whatever the X-rays may be, they are not transverse in character. In fact, the ultraviolet wave theory cannot be longer entertained by any one who has given these phenomena experimental attention.

Though sciagraphs of a sensational character have grown somewhat commonplace, we may be pardoned for presenting another ghostly hand to the public. Two rather successful prior attempts indicated the necessary details for procedure. The result of a third attempt is shown in Fig. 1. An 8 x 10 slow Carbutt plate was carefully folded in cloth, and the subject's hand bandaged over it. The exposure lasted two hours, but

[1] Republished in "The Electrical Engineer," Feb. 26, 1895.

the interrupter breaking down soon after the exposure began, the tube was poorly excited, else the exposure might have been materially shortened. The remarkable clearness of the negative may justfy its use in the present article. The negative from which Fig. 2 is reproduced was the sharpest one we

FIG. 1.

have been able to make. As a negative it is perfect in every respect, the density, sharpness of detail and the clear shadows rivaling the best results obtained by sunlight. This, too, was taken on a slow Carbutt plate. The larger rule was an ordinary boxwood brass-bound one. In the cut the rivets passing through the wood show with singular clearness. The peculi-

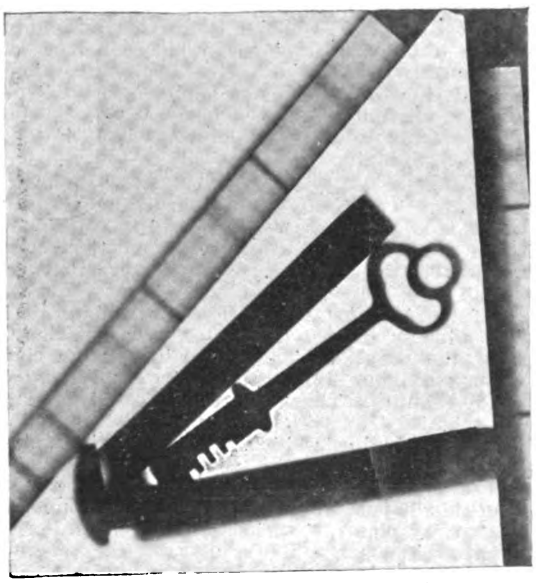

FIG. 2.

arity is that even the graduations were reproduced. Such markings are usually filled with black paint, whose opacity is here clearly indicated. An ivory caliper rule also lay on the plate. For the length of exposure, about one hour, the ivory and metal seem equally opaque. In Fig. 3 two nails and a wood screw driven into the sides of a half-inch oak strip are shown, as well as the grain of the wood. A generalization may be safely made to the effect that animal and vegetable tissues are relatively quite transparent, while mineral and metallic substances are opaque.

Naturally, various light sources were examined for the presence of X-rays. Sunlight gave a negative result, and the arc light as well. So many have fallen into error at this point that it may not be amiss to particularize. It was reported by an English periodical that a sciagraph had been made by burning magnesium ribbon over a covered plate, by a number in this country that sciagraphs had been obtained with the arc light, etc. All our tests of this nature were very carefully made, and yielded clearly negative results, the arc lamp being tested with

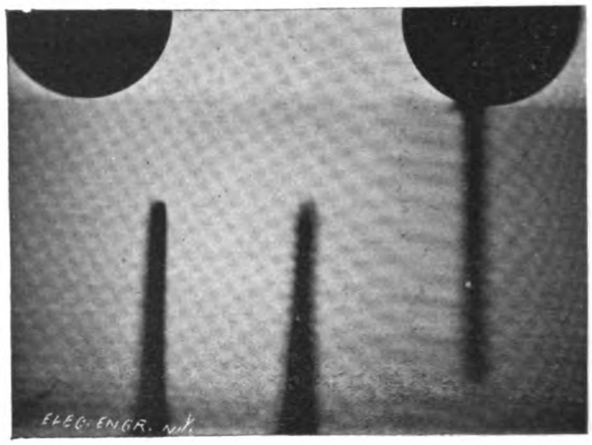

FIG. 3.

especial diligence. The error is readily explained. A plate insufficiently protected is fogged chemically when exposed to stray light, and a light opaque object lying on the plate would impress a distinct shadow. The results already noted have doubtless been of this character. Those experienced in photography well know how difficult it is to keep dry plates from fogging. The so-called magnetic sciagraphs are to be accounted for in the same way. The true test in such cases is to employ an object containing parts opaque and transparent to X-rays, though the object as a whole is opaque to light; for example, a lead pencil or nails in a strip of wood.

A more fruitful source of error has been the use of metallic plates in air. It is safe to state, that in spite of all the reputed results, that not one true sciagraph has been thus obtained; they have been of the character of electrographs. The effect

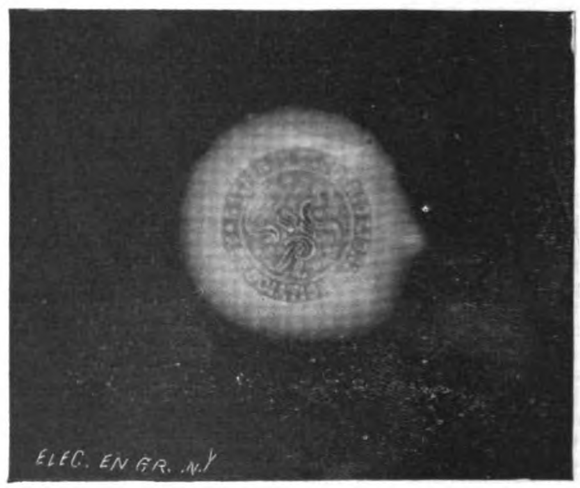

FIG. 4.

of static charges on a dry plate has been fully known for years. Static charges from plates attached to induction coils, Leyden jars, dynamo belts, etc., can be readily made to yield marked effects on photographic plates, even when these are thoroughly covered with cloth, wood, or pasteboard. As in the case of negatives made through fogging, very deceptive outlines are produced, but the experienced eye can readily detect the electrograph from the true sciagraph. The electrograph usually shows a dark object on a clear background; the scia-

graph always shows a more or less clear shadow on a dark background. In some cases the electrograph may closely simulate the sciagraph. In Fig. 4, which is an electrograph of a metallic button, these characteristics are strongly marked, especially if the cut be contrasted with Figs. 2 and 3. So far, true sciagraphs have only been obtained by the use of some modification of the Crookes tube. It is interesting in this connection to note that the electrograph is the result of an electrolytic action on the silver salts in the film of the dry plate. This fact may have a possible bearing on the explanation of the Röntgen phenomena.

The results with aluminum-stopped tubes undoubtedly show the cathode to be the prime source of the X-rays. The penumbra shadows when the object is a little distant from the dry plate, indicate, if such penumbra are plotted back, that the fluorescent bulb is at least a secondary source of the rays. This is in confirmation of Röntgen's original observations. What part does the fluorescence play in such cases? The yellowish-green fluorescence of German glass is due to the uranium it contains. Thinking the particular vibration period of luminescent uranium might have something to do with the phenomenon, the following experiments were tried: A pair of carbons were soaked in a solution of uranium nitrate and a plate exposed to the arc produced between them. A flash powder containing uranium nitrate was fired in considerable quantities near a protected plate. A large cube of brilliantly fluorescent glass was excited with the focused light from the arc lamp, and a plate placed near it. Then another test was made under the same conditions, the cube in this case being constantly charged by a static machine. In no case could the slightest trace of the X-rays be detected. Many other lines of investigation have been examined, and, in passing, we may mention that both the luminous and non-luminous gas flames are practically transparent to X-rays.

It would be rash indeed, at the present stage of experimental evidence, to make strong assertions concerning the production of sciagraphs or the ultimate character of the X-rays; yet our experiments seem to justify us in making some observations. A Crookes tube, to produce sciagraphs, must have an extremely high vacuum, so high that none but the faintest trace of purple light is seen around the anode. The successful tube also shows a decided green fluorescence, while those that fail have a strongly marked yellow cast. A tube improves greatly with use; at the same time the purple light grows less and less perceptible. A tube becomes more active after several hours' constant excitation, provided the current is not reversed. If a tube is allowed to remain idle for several days, it is less active, and the purple light is more marked. These facts may probably be explained by the occlusion in the anode of a portion of the gas present in the tube, thus enhancing the vacuum.

The effect of the X-rays on the dry plate differs radically from that of light. If true ether longitudinal vibrations exist, they must be present in Geissler tubes and all light sources. But the sciagraph does not seem to be the result alone of molecular bombardment by longitudinal vibrations, but rather partakes of the nature of electrolysis. The seat of the effect may be in the molecules containing a charge of static electricity and vibrating with, say, the frequency of green fluorescent or ultraviolet light waves. But would not the Faraday induction tubes concentrate to some extent, at least, on conducting substances, such as metals placed on the dry plate? In the absence of longitudinal ether waves this may be granted. It has been recently stated by a European authority that longitudinal vibrations would follow such induction stress lines. However, sciagraphic negatives disprove such conclusions, for the X-rays seem to travel radially. It more nearly corresponds with the facts to state that should we be here dealing with a species of electrolysis, the induction stress will rather follow and coincide with the longitudinal waves. It will not do to implicitly follow the solution of a particular differential equation before the elements on which such an equation can be based are more clearly established. J. J. Thomson and others have already shown that the X-rays neutralize either positive or negative static charges. But it more fully accords with observed effects to suppose the electric energy is immediately transformed into molecular heat energy. A Geissler tube thus as truly produces the X-rays as the Crookes, but owing to the presence of a great number of charged molecules they are absorbed within the tube itself. The efficient tube is then one in which the free molecular path extends from the cathode to the walls of the bulb, and, further, is not heavily coated on the interior with a static charge.

MANIFOLDING BY CATHODE RAYS.

BY

Elihu Thomson

In order to test the effect of Röntgen rays in producing simultaneously a number of impressions of the shadow of the same object, the experiment described below was made. It

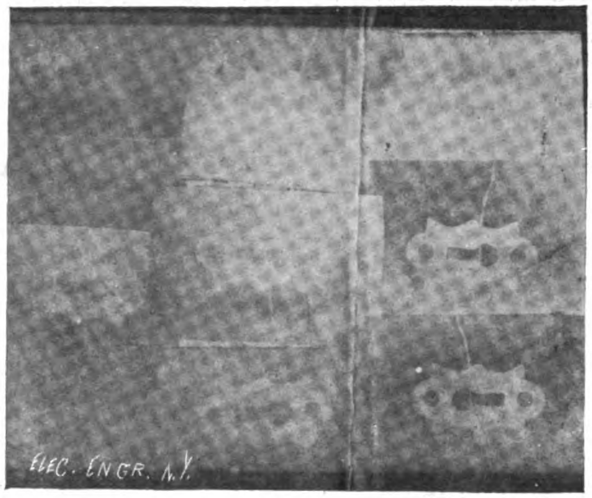

FIG. 1—MULTIPLE CATHODOGRAPHS.

had been found in a preliminary trial that a sensitive plate enclosed in its plate holder folded together with several thicknesses of bromide of silver paper (Eastman's) was strongly impressed through the several thicknesses and at the same time each of the layers received a more feeble impression. In the experiment now to be noted there existed below the Crookes tube the following in regular succession: 1. The object, a keyhole escutcheon of iron. 2. One thickness of heavy yellow paper. 3. One thickness of pasteboard (of box enclosing plate) and within the box. 4. One layer black paper. 5. Two layers of albumen print sensitized paper. 6. Two of célerité printing paper. 7. Two of platinum printing paper. 8. One of célerité printing paper. 9. One sheet thin celluloid. 10. Six layers of sensitive bromide paper. 11. Four layers of sensitive

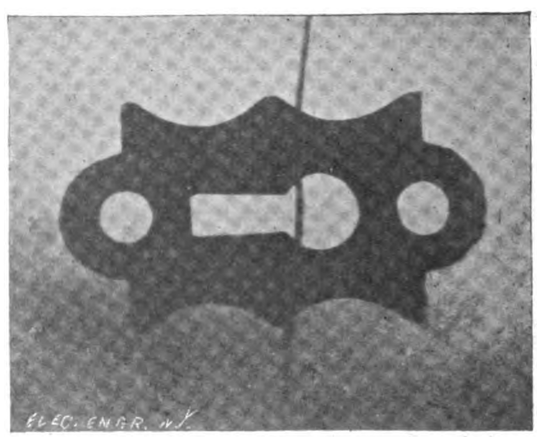

FIG. 2.

bromide paper (heavy). 12. Three layers of black paper. 13. A sensitive glass plate (dry gelatine) with its face up.

Here, then, were twenty-four layers above the plate, including the pasteboard.

The result of the exposure to cathode rays developed in the Crookes tube by about 1,200 discharges of the condenser jars of a small Wimshurst machine gave as a result a strong impression on the glass plate and weaker but perfectly distinct impressions on each of the bromide paper layers. Neither the albumen nor the célerité, nor the platinum papers, which were merely printing papers, were impressed to any discoverable

degree. Had they been bromide they would all have been affected.

The experiment shows that plates for use with cathode rays should have with the ordinary materials, dense thick films, rich in sensitive substances, such as bromide of silver, or that the proportion of material in a plate highly sensitive to cathode rays is not great. The fact that the impressions on the bromide paper were weak, although it was much more favorably situated for a strong impression than the glass plate, is easily accounted for when the relatively thin film ordinarily carried by paper is borne in mind. Could all the sensitive material of the many layers of paper which could easily be impressed at one time, be collected together in one film a dense picture would be obtained at once and from very short exposures.

I think that I have found indications of its being a fact that in cathode pictures, however thin, there is complete detail present, and that an intensifying process which would build up a very thin weak impression need not, as is often the case in ordinary photography, fail to bring out detail. Indeed, by applying the ordinary intensifying processes, details which have been absolutely undiscoverable have shown out distinctly.

STEREOSCOPIC ROENTGEN PICTURES.

BY ELIHU THOMSON.

WHILE experimenting with the making of shadow pictures, it occurred to the writer that it would be desirable to secure some indication of the position in space of various embedded solid objects, or, in other words, to obtain a pair of pictures which, when placed in a stereoscope would show solidity. This would manifestly be useful in surgical examinations, as the true relations in space of the parts of a bone, or of a foreign body and the bone would become evident. The ordinary Röntgen pictures are simple shadows on a plane surface. It is impossible to tell from such a shadow whether one object or part of an object is front or back of another. There is, however, no difficulty in determining the real positions when resort is had to the production of stereoscopic shadow pictures.

The first trial made by the author was completely successful, objects appearing in high relief. The process consists simply in exposing a covered plate in the ordinary way and repeating this with the objects and Crookes tube relatively displaced somewhat from the first position. The rays thus pass through the objects in two somewhat different directions, a record of the shadows being made for each direction. Prints from the negatives so produced are mounted for use in the stereoscope. The effect is very curious. A cork or block or wood having nails or screws driven into it in various directions is clearly shown and the screws or nails in their proper positions. When two heavily insulated wires twisted together constitute the object, the metal wires alone are seen, but standing apart in space, one around the other.

The bones of two superposed figures are to be seen in their correct positions. The complete skeleton of a mouse or other small animal may thus be recorded so as to be seen in relief, each bone in its proper space relation to the others.

It may be possible as a development of the use of Röntgen rays stereoscopically to arrange two fluorescent screens, or even a single screen, to be viewed by the eyes and receive the image or shadow in such manner as to produce the stereoscopic effect; thus, if the Crookes tube have two cathodes a distance apart, which are connected to the electric source alternately, and with considerable rapidity, while small shutters are synchronously opened and closed before each eye, respectively, one of the eyes would at all times receive the impression given by the rays from one of the cathodes, while the other eye would always receive the impression produced by the rays from the other cathode, and thus stereoscopic observations would be the result.

This method of producing the stereoscopic effect is similar to one which has been tried and used successfully in stereopticon work, two lanterns being arranged to throw upon the same screen in nearly superimposed positions two slides, which are stereoscopic in their relation to each other. A set of diaphragms were arranged, passing in front of the lantern tubes synchronously with similar diaphragms, passing before the eyes of the spectators, whereby each eye always received its appropriate image on the screen, the result being to give solidity to the scene depicted.

FLUSHING, L. I.—The Flushing Electric Light and Power Company has placed an order with the Ames Manufacturing Company, of Oswego, N. Y., for an engine of 190-horse-power to be delivered at once.

SHADOW PICTURES FROM THE ARC AND SUNLIGHT.

BY W. H. FREEDMAN, E. E.

AS a result of the most wonderful scientific discovery by Professor Röntgen and the widespread attention it has received, the thought occurred to the writer whether the same or similar effects could not be obtained from other sources of light instead of being produced only by the peculiar conditions set up by an electric discharge in a Crookes tube.

Together with Mr. C. T. Rittenhouse, Fellow in Electricity at Columbia College, an investigation was begun (since continued single-handed) obtaining several interesting results, entirely at variance, however, with those claimed by Mr. J. Hart Robertson in the issue of "The Electrical Engineer" of Feb. 19, 1896.

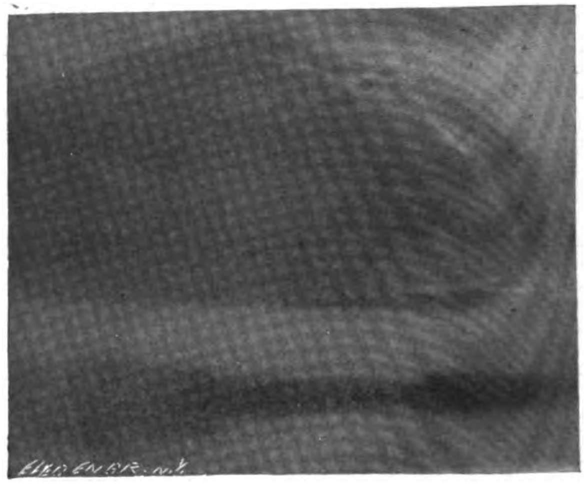

FIG. 1.—AN ARC LIGHT SHADOW PICTURE.

On Feb. 6, a plate holder, containing an ordinary sensitive photographic plate and having a slide of hard rubber, 0.025 of an inch thick, was placed eight inches from an arc light. In front of the plate holder were fastened a screwdriver and a leather case containing a pair of eyeglasses. About midway between the arc and the holder a piece of cardboard, .031 of an inch thick, was placed to act as a screen to shield the plate from the intense heat. After an exposure of five hours the plate was developed, giving Fig. 1.

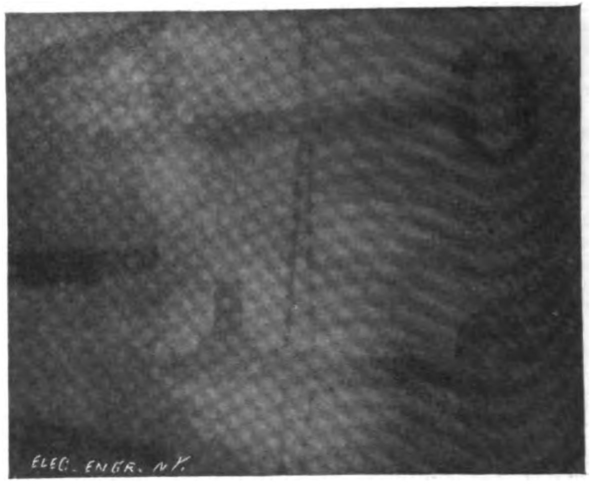

FIG. 2.—A SUNLIGHT SHADOW PICTURE.

This plate of itself is sufficient proof that there are no Röntgen rays emanating from the arc or at least so few that they cannot be detected. For if the impression on the plate were due to Röntgen rays the iron of the screwdriver should show inside of the wooden handle and the eyeglasses should show inside of the leather case.

It was somewhat of a surprise that ordinary light should penetrate cardboard and hard rubber so easily. To satisfy himself the writer determined to expose a plate holder to the

action of the sun, since the spectra of the arc and the sun are very similar.

On Feb. 7, after an exposure of 4½ hours, a fair shadow picture of an ink eraser, penholder and pens was obtained. A second holder on which were fastened two keys (tied with string) and several pens gave, after 6½ hours' exposure, a rather fine plate (Fig. 2). The string casting a heavy shadow again shows the effect to be due to ordinary light.

As additional proofs that these shadow pictures obtained from the arc and the sun are due solely to the filtration of ordinary light, I have the following results of further tests to offer:

1. Glass which casts a heavy shadow to Röntgen rays casts none whatever in any of these instances.
2. When the plate holder used was closed by means of an aluminum slide instead of hard rubber, no shadow picture was obtained. The aluminum slide used was only .01 of an inch thick and is rather transparent to Röntgen rays as proved by many skotographs obtained by Dr. Pupin through slides cut from the same sheet of metal.
3. Plate holders were placed so that the rays of light struck them at an acute angle. In no case was a shadow picture obtained, showing that reflection took place and proving the absence of Röntgen rays.

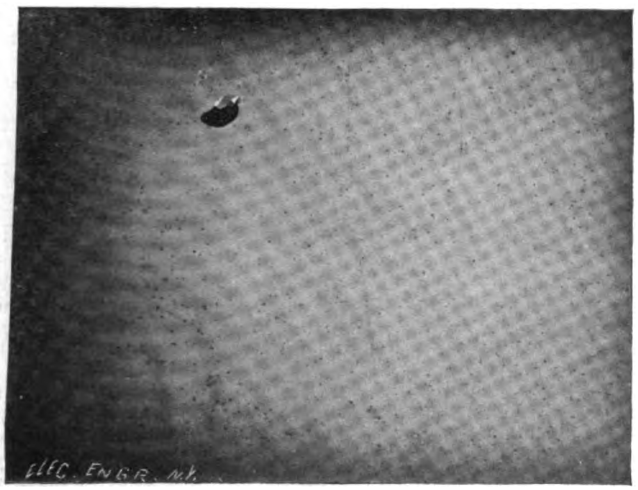
The writer has other results at his disposal, but reserves them till the entire investigation will be completed.

A MAGNET CATHODOGRAPH.

BY E. B. FROST.

AMONG the numerous photographs obtained with the X-rays in the Dartmouth Laboratory, the one illustrated is of perhaps especial interest to electricians. It was secured about February 15 by Mr. F. E. Austin, graduate scholar in physics, under conditions about as follows: A small horseshoe permanent magnet was laid flat upon one end of the plateholder, with its poles pointing toward a small bar magnet placed on the opposite end of the plateholder. Our most efficient tube, No. 1,147, in the catalogue of the maker, Dr. Stöhrer, of Leipzig, was used as the source, being placed horizontally, about 15 cms. above the plate.

A glance at the plate at once suggests that we have here



A SUPPOSED MAGNET CATHODOGRAPH.

magnetic lines of force, depicted without the intervention of iron filings or other substances. But we by no means assert that they are really lines of force. Unfortunately, the exact data of the experiment were not recorded, so that we are not absolutely sure that we have precisely repeated the conditions of the exposure in our subsequent attempts. In no case have we obtained any plate like this one, but we have become rather superstitious that the presence of a magnet near a plate renders it liable to fog. Ordinarily, the magnets exhibit the usual metallic obstruction without any such markings as above. However, if the result depends upon having the magnets separated by a distance which must be accurate within a millimetre and having both at a certain precise distance from the source, then it is not likely that we have yet exactly repeated the conditions of the original experiment. Other plates from the same lot exposed under other conditions, but similarly developed, show no markings, so that it seems difficult to believe that the impression was originally on the plate or arose during development. The spots scattered over the plate are due to holes in the film, but we know of no cause for them.

We have endeavored to account for the appearance of the plate on the assumption of mechanical vibrations of the plate from the neighboring interrupter of the induction coil, but this seems hardly a sufficient cause. The result, however, is entirely objective, and we present it in the hope that it may be confirmed by other experimenters, or that suggestions as to the cause may be given from the experience of others. Meanwhile the experiments of Professor Emerson and myself will be continued with a view to a repetition of the result.

ELECTRIC IMAGES WITHOUT CROOKES TUBES.

BY R. K. DUNCAN.

THE writer has obtained a fine positive impression of a silver dollar on a sensitive plate, showing plainly the head of Liberty and the date by passing a current of 52 volts and 15 amperes into a large induction coil to the terminals of

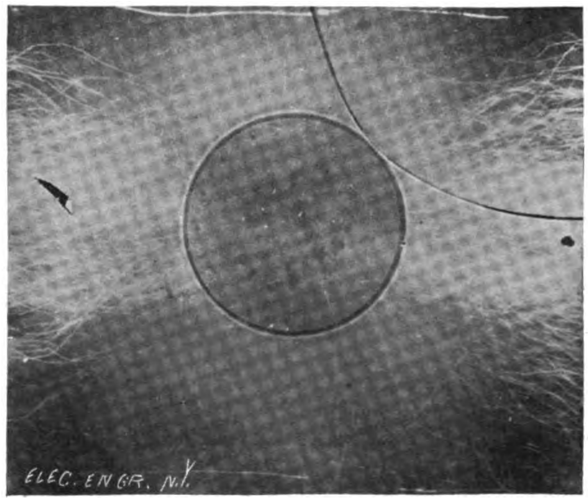


FIG. 1

which were connected two brass plates. The plate holder with the plate and coin in position, both being covered carefully by the ebonite slide, were placed between the two brass plates and the current passed for twenty-five minutes. From each side of the picture of the coin so produced a great brush of fine lines radiates out (Fig. 1). These brushes apear to me to show that the positive of the coin is due simply to electrolytic

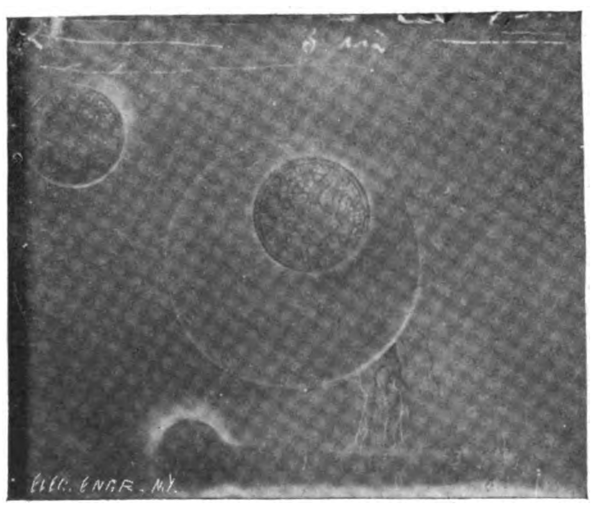

FIG. 2.

action and not to the impact of X-rays, as stated by Morton and others.

Under the impression that the interposition of glass between the terminal and plate holder might interfere with the formation of the image ,the writer then connected one ter-

minal of the induction coil to an ordinary incandescent light bulb with a broken filament and the other to a plate of tinfoil. A silver quarter was placed on the sensitive plate in the plate holder and a watch glass placed carefully over it. Both glass and coin were then covered by the slide and the plate holder was placed on the tinfoil plate. The bulb containing the negative terminal was moved over the surface of the slide. At first the bulb was filled with cathode rays, but a spark soon perforated the glass and destroyed the vacuum. The character of the discharge then resembled that between the two brass plates with the exception that the sparks were now confined to the glass bulb and that the coin was protected by a watch glass. On development there was to be seen not only a very fine picture of the coin, but, curiously enough, a picture of the watch glass in addition. (See Fig. 2.) There is also an absence of the radiating brushes in the brass plates experiment.

ULTRA VIOLET RAYS AND LAMPS ADAPTED TO PRODUCE THEM.

BY HERBERT COTTRELL.

In the year 1852 Professor Stokes communicated to the Royal Society his discovery of what is now called fluorescence. He described the "long spectrum of the electric light," and referred to the "invisible rays outside of the blue end of the spectrum" as being capable of being "rendered visible."

In order to get this invisible light in better condition for testing, he tried the transparency of various substances through which this light would pass, and observed that these rays passed through glass with extreme difficulty. He found, however, that "quartz allowed these invisible rays to pass" with great freedom.

Continuing his observations, he found "in the case of a spark discharge between the poles of an induction coil, that the visible spectrum which was revealed and rendered visible by means of fluorescence, was no less than six or eight times longer than the whole of the (ordinarily) visible part of the spectrum."

Later Professor William Crookes experimented with high potential electric discharges, in tubes exhausted to the highest possible degree, and accomplished what had before been supposed impossible, by showing that such electrical discharge acted across an almost perfectly vacuous space. This electric action rendered the whole interior of such tubes luminous. He discovered also that "these rays proceed in direct lines from the surface of the cathode," and he tried their effect upon many incandescing and phosphorescing substances, obtaining very beautiful luminous effects.

Now Professor Röntgen, employing the discoveries of Professors Stokes and Crookes, shows that he can print the shadow which some of the substances least transparent to the cathode rays cast upon a sensitive photograph plate.

Is this discovery of any practical value? Many think it is, and are most energetic in experimental work on that line. In order to proceed, a proper lamp is the most important requirement. The experience of several years in this branch of electrical work leads the writer to conclude that, whether the line of research is to make shadow prints, or whether it is to produce luminous effects, practically the same condition applies, which is this: that the lamp must be constructed on the principle of an electric condenser; the subjecting to the action of a varying electromagnetic or electrostatic field; of one condenser surface exposed to the vacuum of an exhausted receptacle, and another condenser surface exterior to such receptacle and exposed to air.

An old incandescent lamp (if the state of exhaustion is still of the most perfect character), will do by applying tinfoil to a portion of the outer surface, and then connecting the terminals, from a proper source of electricity, respectively to the filament and the tinfoil. But the best results should not be expected with such a lamp, for one reason, that the filament is not the best form of inner terminal, and also because the incandescent lamp cannot be depended upon to have a sufficiently perfect vacuum for this purpose; besides, the usual form of the incandescent lamp is not well adapted to the application of the foil for use as a reflector.

Those who have facilities to make and exhaust a bulb, will find a spherical one made very thin, to be preferred to the ordinary pear-shaped bulbs. For the inside electrode, carbon in the form of a ball, is good, or, if a metal is preferred, it will be found that aluminum is better that platinum, because platinum disintegrates, by a sort of electrolytic process, and deposits on the interior surface of the bulb and blackens it. A good cement for the carbon electrode consists of 100 grs. carburet of iron, 10 grs. lump sugar, 40 grs. gold bronze. Grind to powder, mix with water to a thick paste, apply and let stand about 20 minutes, then burn to a cherry red in alcohol or gas flame.

Tinfoil is a very good coating for the outside electrode, and may be applied with any suitable adhesive material, or with mercury, as in the mirror-making process.

The exhaustion should be carried to the greatest possible degree. Lamps with "shutters," which are liable to leak, should be constructed so as to be again put on the pump, as they may have to be exhausted repeatedly.

A non-conductive "shutter" should be better than a conductive one, if some material other than aluminum can be used, for securing the difference of potential between the inside and the outside of the bulb.

ON RADIANT MATTER.—IV.

BY WILLIAM CROOKES, F. R. S.

The molecules being driven violently from the pole, there should be a recoil of the pole from the molecules, and by arranging an apparatus so as to have the negative pole movable and the body receiving the impact of the radiant matter fixed, this recoil can be rendered sensible. Fig. 12 represents an apparatus whose appearance is not unlike an ordinary radiometer, with aluminum discs for vanes, each disc coated on one

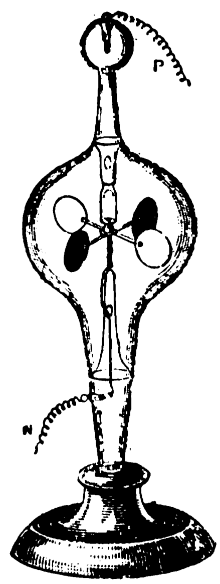

FIG. 12.

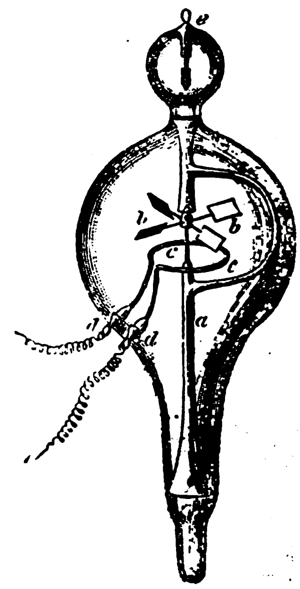

FIG. 13.

side with a film of mica. The fly is supported by a hard steel instead of glass cup, and the needle point on which it works is connected by means of a wire with a platinum terminal sealed into the glass. At the top of the radiometer bulb a second terminal is sealed in. The radiometer therefore can be connected with an induction-coil, the movable fly being made the negative pole.

For these mechanical effects the exhaustion need not be so high as when phosphorescence is produced. The best pressure for this electrical radiometer is a little beyond that at which the dark space round the negative pole extends to the sides of the glass bulb. When the pressure is only a few millims. of mercury, on passing the induction current a halo of velvety violet light forms on the metallic side of the vanes, the mica side remaining dark. As the pressure diminishes, a dark space is seen to separate the violet halo from the metal. At a pressure of half a millim. this dark space extends to the glass, and rotation commences. On continuing the exhaustion the dark space further widens out and appears to flatten itself against the glass when the rotation becomes very rapid.

Fig. 13 represents another piece of apparatus which illustrates the mechanical force of the radiant matter from the negative pole. A stem (a) carries a needle-point in which revolves a light mica fly (b b). The fly consists of four square vanes of thin clear mica, supported on light aluminum arms, and in the center is a small glass cap which rests on the needle-point. The vanes are inclined at an angle of 45 degress to the horizontal plane. Below the fly is a ring of fine platinum wire (c c), the ends of which pass through the glass at d d. An aluminum terminal (e) is sealed in at the top of the tube, and the whole is exhausted to a very high point.

By means of the electric lantern an image of the vanes was

projected on the screen. Wires from the induction-coil were attached, so that the platinum ring was made the negative pole, the aluminum wire (e) being positive. Instantly, owing to the projection of radiant matter from the platinum ring, the vanes rotated with extreme velocity. Thus far the apparatus had shown nothing more than the previous experiments had prepared us to expect; but another phenomenon was then exhibited. The induction-coil was disconnected altogether, and the two ends of the platinum wire connected with a small galvanic battery; this made the ring c c red-hot, and

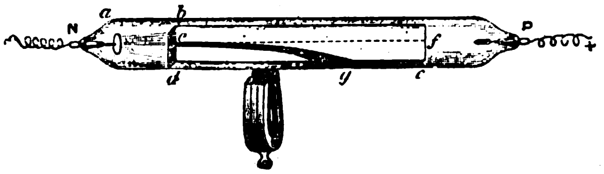

FIG. 14.

under this influence it was seen that the vanes spun as fast as they did when the induction-coil was at work.

Here, then, is another most important fact. Radiant-matter in these high vacua is not only excited by the negative pole of an induction-coil, but a hot wire will set it in motion with force sufficient to drive round the sloping vanes.

We now pass to another property of radiant matter. The long glass tube, shown in Fig. 14, is very highly exhausted; it has a negative pole at one end (a) and a long phosphorescent light (e, f) was projected along the whole length of the tube. A powerful horse-shoe magnet was now placed beneath the tube, and the line of light (e, g) became curved under the magnetic influence, waving about like a flexible wand as the magnet was moved to and fro.

This action of the magnet is very curious, and, if carefully followed up, will elucidate other properties of radiant matter. Fig. 15 represents a tube exactly similar, but having at one end a small potash tube, which, if heated, will slightly injure the vacuum. When the induction current is turned on, the ray of radiant matter is seen tracing its trajectory in a curved line along the screen, under the influence of the horse-shoe magnet beneath. Let us observe the shape of the curve. The molecules shot from the negative pole may be likened to a discharge of iron bullets from a mitrailleuse, and the magnet beneath will represent the earth curving the trajectory of the shot by gravitation. The curved trajectory of the shot is accurately traced on the luminous screen. Now suppose the deflecting force to remain constant, the curve traced by the projectile varies with the velocity. If more powder be put in the gun, the velocity will be greater and the trajectory flatter; and if a denser resisting medium be interposed between the gun and the target,

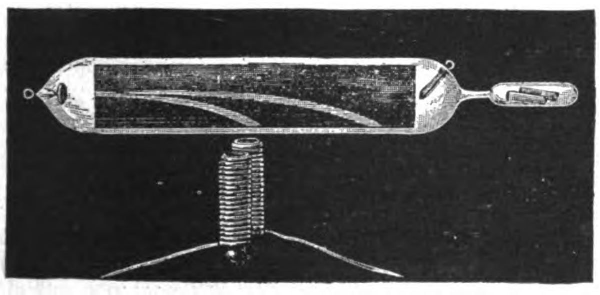

FIG. 15.

the velocity of the shot will be diminished, and it will move in a greater curve and come to the ground sooner. The velocity of this stream of radiant molecules cannot well be increased by strengthening the battery, but they can be made to suffer greater resistance in their flight from one end of the tube to the other. In the experiment shown, the caustic potash was heated with a spirit-lamp, and so a trace more gas was thrown in. Instantly the stream of radiant matter responded. Its velocity was impeded, the magnetism had longer time on which to act to get the molecules, the trajectory became more and more curved, until, instead of shooting nearly to the end of the tube, the "molecular bullets" fell to the bottom before they had got more than half way.

ST. JOSEPH, MO., has had enough of municipal plant lighting, and it is now proposed to sell the plant because it cannot be run on a paying basis.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—III.

BY

Wm Baxter Jr

As already stated, the saving in coal consumption is not the only way in which electricity can reduce the cost of operating steam roads, nor can the saving in this item alone be expected to amount to anything very formidable, certainly not enough so as to determine the superiority of the system over steam. Nevertheless, the gain in this direction is one of the important factors that will contribute toward making electricity the most economical of the two. It will be well, therefore, to look into this matter and see how much we can reasonably expect the gain in this direction to be. This we can easily do by taking the coal consumption and total operating expenses on several roads, and making the proper deduction therefrom.

From the report of the New York Central Railroad we find that the number of locomotives is 1,197, and if we assume the saving per locomotive per year to be $1,300, as already deduced, the total yearly saving would be $1,556,100, which is about 5 per cent. of the entire operating expenses. If we assume that the saving in coal per unit of energy delivered on the track is 55.6 per cent., as already shown, and take this proportion of the coal bill as the saving, we will then have $1,685,652.87, and this amounts to about 5½ per cent. of the total operating expenses.

Taking the percentage that the coal bill constitutes of the total operating expenses of the roads already considered, and estimating the saving in each on a basis of 55.6 per cent., we obtain the following tabulated results:

Table 2.

Table Showing Percentage of Operating Expenses Saved by Reduced Coal Consumption on the Roads Named.

	Per Cent.
New York Central	5.5
Boston and Albany	5.8
Albany and Susquehanna	10.0
New York, Lake Erie and Western	5.27
New York, New Haven and Hartford	5.0
Boston and Maine	5.5
Pennsylvania Railroad	5.0
Philadelphia and Reading	4.5
Lake Shore and Michigan Southern	5.8
Pittsburg, Cincinnati, Chicago and St. Louis	3.4
Total	55.77
Average	5.57

We see from these figures that the greatest saving in any one case is 10 per cent. of the total expenses of operating the road, while the lowest is 3.4 per cent., the average being about 5½ per cent. It may be claimed by the advocates of steam that these results cannot be realized in practice. Whether they can or not depends upon the accuracy of the assumptions upon which the estimated saving of 55.6 per cent. is based. If the claims that have been made in favor of locomotives were strictly true these results could not be obtained; but these claims are not in accordance with actual facts. The assumption that the coal consumption of locomotives is about sixty pounds per mile only holds good for high speed passenger engines. The report of the Commissioner of Railroads of the State of Ohio for the year 1894 shows that the average coal consumption of all the locomotives in the State was at the rate of 83.48 pounds per mile. The lowest figure given is 46 pounds per train mile, and the highest 256.65 pounds. The report of the State of Illinois gives the figures more in detail, and shows that the coal consumption per train mile is as follows:

Table 3.

Coal Consumption Per Train Mile on Roads in State of Illinois.

	Pounds.
Coal per passenger train mile, average	64.52
Coal per freight train mile, average	104.84
Lowest consumption per passenger train mile	39
Lowest consumption per freight train mile	66.66
Highest consumption per passenger train mile	115.55
Highest consumption per freight train mile	150.76

These figures, together with those given in the report of the State of Ohio, represent the actual performance on about two hundred roads. It will therefore be seen that the claim that has so often been made that locomotives only consume from fifty to sixty pounds of coal per train mile is very far from being true. The average consumption for Ohio is over 83 pounds. The average for the State of Illinois is 84.68 pounds, which is still higher. The estimated saving of electricity over steam by which the results given in Table 2 are obtained, is based on the assumption that the average coal consumption of locomotives is 80 pounds per train mile, and this, it will be seen, is within the actual results obtained in practice.

In so far as the electrical efficiency is concerned, the assumed saving is based on the supposition that the coal consumption in the station would be at the rate of two pounds per hour per horse-power, and that 60 per cent. of the energy of the steam engines could be delivered on the track. Both these assumptions are realized in practice every day.

Table 4.

Passenger Traffic in State of Illinois for 1894.

Miles run by trains	29,235,262
Passengers per train	54
Number of cars	6,915
Number of locomotives	2,083
Average weight of locomotive and tender ...... lb	175,000
Average weight of cars ...... lb	68,000
Average number of cars per train	4
Average weight of train ...... lb	450,000
Average speed of train ...... miles	35
Average coal consumption per train mile ...... lb	64.52
Average coal consumption per hour ...... lb	22.58
Average horse-power required	252
Average coal consumption per hour ...... lb	9
Number cars per locomotive	3.3

I do not pretend to say that the efficiency of locomotives is not as high as it is claimed to be. There can be no doubt about the fact that while in motion the coal consumed per horse power is somewhere in the neighborhood of 3½ or 4 pounds in passenger engines running at a high speed, and perhaps not more than six pounds in heavy freight locomotives, but the total consumption per day, divided by the actual energy developed will show results far below these figures. Every minute that an engine stands still on the track coal is wasted. This does not amount to a serious loss in express passenger engines, because the stops are at long intervals and not of great duration, but in local passenger traffic it amounts to considerable, because of the greater frequency of the stops. In freight trains it assumes a decided importance because it is a very common occurrence for a train to be side-tracked for periods of time ranging from ten or fifteen minutes to an hour or more.

It may be claimed that the fact that the average coal consumption per hour is high is no proof that the efficiency is low, or, in other words, that the pounds per horse-power hour are high; as this large consumption of coal may be interpreted to mean that the average weight of trains is very high and therefore that the energy developed may be enough to bring down the consumption per horse-power hour to a low figure. The only way by which this point could be accurately determined would be by knowing the actual weight and speed of trains. If railroad reports were gotten up with the special view of obtaining such information it would be possible to furnish positive data on the point. But these reports are not made for that purpose; therefore it is only by taking information from several different sources that any data sufficiently reliable to be used as the basis of calculations can be obtained. By such data Tables 4, 5, 6 and 7 have been made out.

Table 5.

Total Movement in State of Illinois for 1894.

Tons carried one mile	6,050,197,710
Miles run by trains	37,801,675
Tons per train	160
Number freight cars	249,537
Number freight locomotives	4,797
Number of cars per locomotive	52
Average weight of locomotive and tender ...... lb	150,000
Average weight of car ...... lb	24,000
Average number of cars per train	20
Average number tons freight per train	160
Average weight of train ...... tons	475
Average speed per hour ...... miles	15
Average coal consumption per hour ...... lb	1,575
Average coal consumption per train mile ...... lb	105
Average horse-power required	151
Average coal consumption per hour ...... lb	10.4

In Table 4 the average number of passengers carried in a train has been obtained by dividing the total number of passengers carried one mile by the number of miles run by the trains. The number of cars, divided by the number of locomotives used in the passenger service, gives the average number of cars for each locomotive. This, as will be seen, is 3.3. The number of cars per train has therefore been assumed to be 4, which is certainly not under the actual number. The weight of cars and locomotives is not given in the reports of the State of Illinois; neither is the speed of trains. This data which is presented in Tables 6, 7 and 8, has been obtained from the report of the New York Central Railroad, the Pennsylvania Railroad, and also through the courtesy of Mr. Theo. N. Ely, Chief of Motive Power of the Pennsylvania Railroad. The speed of trains is the average of the Pennsylvania Road. It must therefore be conceded that the number of cars per train is at least up to the average, while the weight is the average of the maximum weight of cars used on the New York Central Road, and certainly is not below the average weight of all passenger cars in the State of Illinois.

Table 6.

Weight of Cars, Taken from Report of New York Central Railroad. Weight of Freight Cars—Maximum.

	Pounds.
Box	33,000
Stock freight cars	30,000
Coal freight cars	30,000
Flat freight cars	21,000
Caboose, 4 wheels	10,000
Caboose, 8 wheels	30,000
Service cars	18,000
Average maximum weight	24,000
Weight of Passenger Cars—Maximum.	
First-class passenger car	82,000
Second-class passenger car	48,000
Baggage, mail and express cars	75,000

The weight of train, which is taken at 450,000 pounds, is certainly much higher than the average, and so is the speed, but with these figures, we find that the coal consumption per hour is 35 (miles) × 64.52 (lb) = 2,258 lb, and the power required to move the train at 35 miles per hour is:

$$\frac{35 \times 5{,}280 \times 225 \text{ (tons)} \times 12}{60 \times 33{,}000.} = 252 \text{ H. P.}$$

In the above fraction 12 is the number of pounds pull required to draw one ton. Further

$$\frac{2{,}258 \text{ (lbs coal)}}{252 \text{ (H. P.)}} = 9 \text{ lb coal (approx.) per horse power hour.}$$

From this we see that even by making the most liberal calculation in favor of the locomotive, we cannot show that the average performance exceeds an efficiency of 9 pounds per horse-power hour.

Table 7.

Freight Train Data—From Pennsylvania Railroad.

Number of tons carried one mile	6,471,866,950
Number of freight trains	445,052
Number of mixed trains	25,195
Miles run by freight trains	20,400,355
Miles run by switching trains	10,298,317
Miles run by construction and other trains	953,064
Average number of freight cars in a train	30.14
Average number loaded cars in a train	18.84
Average number of empty cars in a train	11.30
Average number of tons of freight in a train	317.25
Average number of tons of freight in each loaded car	16.84
Average speed of freight trains, Pennsylvania Railroad Division, miles per hour	15
New Jersey Division, miles per hour	18
Pennsylvania and Essex Division, miles per hour	12

In respect to the freight traffic, the calculation for determining the coal consumption per horse-power has been made in the same liberal manner, but for all that the amount runs up to 10.4 pounds per hour. By dividing the tons of freight moved one mile by the miles run by trains, as given in Table 3, we find the average number of tons per train is 160. In Table 6 it will be seen that the average number of tons of freight for a train of thirty cars is 317, or at the rate of about ten tons per car.

Now as the average tons of freight train in Table 5 is 160, the average number of cars should be sixteen; but it has been taken at twenty, in the calculation of horse-power, so that the result obtained is certainly better than the actual practical performance, and this is on the assumption that freight trains in Illinois carry as much load on an average as they do on the Pennsylvania Road. This calculation of the power required to move the average freight train is made on the basis of 8 pounds tractive force per ton, which is a liberal figure for a speed of fifteen miles per hour.

These calculations of coal consumption which are based on

Table 8.

Passenger Train Data, Pennsylvania Railroad.

Number of miles run by passenger trains.........	14,908,880
Number of passenger trains......................	389,965
Number of passengers carried one mile	748,872,408
Average number of passengers per train........	100
Speed of Passenger Trains.	
Average speed of ordinary passenger trains, miles per hour, Pennsylvania Railroad Division....	38
New Jersey Division	30
Pennsylvania and Essex Railroad Division......	25

New Jersey Division...........................	40

the actual every-day work of about 100 roads, show that the claim that has so often been made that the margin for improvement in the performance of locomotives is so small that any gain that can be made would not be sufficient to materially reduce the operating expenses of a road, is not sustained by the facts. It is very true that the coal bill does not constitute a very large portion of the total expenditures, but it may safely be taken as amounting to 10 per cent., on an average, of the whole expenses of operating a road.

UNSUCCESSFUL TROLLEY FREIGHT SERVICE IN CALIFORNIA.

One experiment in an electric railroad express business has, it is said, failed. For over a year a street railroad company has been doing about all the express business between Haywards, San Leandro, Oakland, and San Francisco. It commenced by buying out all the smaller companies and by inaugurating a regular electric express service. The loaded wagons were placed on electric cars, and during the quiet portions of the day were attached to the regular passenger cars. The first opposition met with was from the Railroad Commissioners, who claimed that as the road was doing a railroad freight business it came under the same tariff regulations as other railroads. That matter might have been adjusted, but the service has been abandoned because it was not profitable, although the rates charged were only about one-half what the smaller companies had charged. The service was not acceptable to the people, the Secretary of the railroad company explains.

News and Notes.

JACQUES' METHOD OF OBTAINING ELECTRICITY DIRECT FROM CARBON.

THE conversion of the energy of carbon directly into electrical energy, without the medium of the steam engine and dynamo, has long since become the goal for which electricians are striving. The most recent attempt at the solution of this problem is that embodied in a patent just issued to Dr. W. W. Jacques, of Newton, Mass, well known in connection with telephone work.

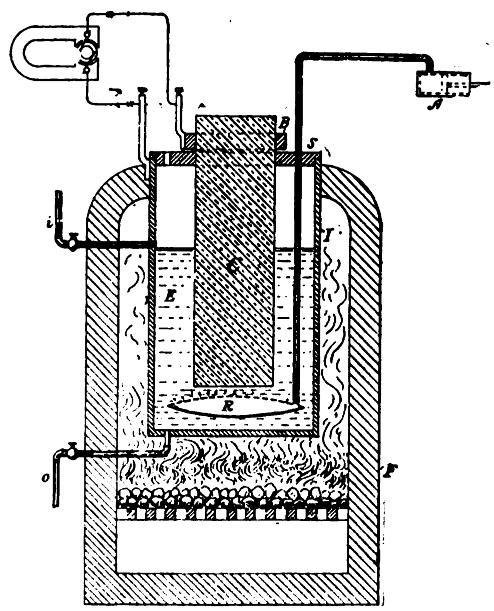
Dr. Jacques has discovered that if oxygen, whether pure or diluted, as in air, be caused to combine with carbon or carbonaceous materials, not directly, as in the case of combustion, but through an intervening electrolyte, the potential energy of the carbon may be converted directly into electrical energy instead of into heat.

A practical way of carrying out this method is to immerse a cylinder of carbon in molten sodium hydrate and to force a current or blast of air into the molten sodium hydrate in such manner that it becomes impregnated with oxygen in excess over that which sodium hydrate normally contains. A circuit being completed from the sodium hydrate, which is the electrolyte, by means of a collecting-electrode not chemically acted upon by the electrolyte and an extraneous conductor to the carbon, an electric current flows continuously from the sodium hydrate through the collecting-electrode and the exterior conductor to the carbon, the strength of the current depending primarily upon the rapidity with which the air is blown into the sodium hydrate, and the oxygen of the air caused to combine with the carbon.

The arrangement for carrying out the process is shown in the accompanying illustration. The carbon C, is immersed in the caustic soda solution E. A pump A, forces air into the rose R, which distributes it evenly into the electrolyte. The solution is contained in the Norway iron pot I, which forms the positive terminal, the negative B being clamped to the carbon C, which is supported by the insulating cover S. The caustic soda solution is admitted and removed by the pipes i and o. The whole is surrounded by a furnace F, which maintains the active cell at a temperature of 400 to 500 degrees Centigrade.

In this process the carbon is gradually converted into carbonic acid, which mostly bubbles up through the electrolyte and escapes. The resultant composition of the sodium hydrate remains unchanged, except as shown below, and oxygen of the air is consumed. The nitrogen with which the oxygen of the air is diluted, having no chemical affinity for any other substance present, simply bubbles through the electrolyte and escapes.

Dr. Jacques' conception of the function of the electrolyte is that it carries oxygen electrolytically from the air to the carbon, or that the phenomenon of electrolytic action causes the



JACQUES' CARBON CONSUMING ELECTRIC GENERATOR.

conversion of the potential energy of the carbon into electrical energy instead of into heat, as is the case when oxygen combines with carbon without the intervention of an electrolyte.

Although the greater part of the carbonic acid, whether resulting from the union of carbon and oxygen already existing in the air supply, bubbles up through the electrolyte and escapes, a portion of the carbonic acid combines with a portion of the caustic soda to form carbonate of soda, and this, together with the ash from the carbon, slowly contaminates the electrolyte, and in the course of time lessens its efficiency. The efficiency may be maintained by drawing off from time to time a portion of the contaminated electrolyte and admitting a fresh portion to take its place.

The contamination of the caustic soda by its union with carbonic acid may be reduced, and its life prolonged, by adding a small percentage of oxide of magnesium. According to Dr. Jacques, the action of the oxide of magnesium is that the free carbonic acid combines with it in preference to the caustic soda, and that the carbonate of magnesium so formed is quickly decomposed into carbonic acid, which escapes, and oxide of magnesium which is again ready to repeat its action. Briefly, the oxide of magnesium serves as a carrier to convey the carbonic acid through the electrolyte.

The current obtainable by this type of generator is said to be very large, but the voltage, which is not given by Dr. Jacques, is low.

"THE ENGINEERING MAGAZINE" for March contains a Röntgen article by Dr. Pupin and an article on "Lighting Residences by Electricity," from the pen of Mr. Augustus Noll.

STANDARDIZING THE RULES FOR CONSTRUCTION AND OPERATION.

THE fact that next week will witness the gathering in this city of a number of representative men for a conference on the subject of standardizing the rules which govern electrical construction and operation and which lie at the basis of electrical insurance, prompts us to the expression of a fervent hope that the occasion will realize all that the organizers of the conference propose. This subject of unification has already been several times advocated in these pages, and it is encouraging to find that so definite an approach to common and harmonious action is now likely of success.

The names of the various bodies and leading corporations that are to confer have been given to the public, and this week is added a list of delegates invited to attend in an advisory capacity, as representative of the general interests of the electrical profession. We note also that an invitation has been issued also to the Underwriters' National Electric Association to co-operate. While that body is closely identified with the National Board of Fire Underwriters, its important work in the preparation and enforcement of good rules gives it the right to a place of its own in these counsels.

It is understood that the conference will not attempt legislation, but we shall be greatly disappointed if, with the excellent codes before it, the various growth of the experience of past years, it cannot produce a standard national set of rules which every organization that has been represented in its preparation will be glad to approve and sanction. The time is rife for such a codification. The gain to the electrical arts will be immense. The saving to the insurance interests will be incalculable. A set of rules everywhere known to have behind it the weight of general sanction will carry with it an official authority that no single set and no individual practice could ever secure. At the present moment there is confusion and conflict, but it is wholly unnecessary, and should be succeeded by a peace due to scientific legislation. We venture to ask for the conference the cordial support and active interest of all who desire to see electricity outrank other agencies as the safest and best, whether for life or for property, in the distribution of light, heat, power, intelligence, and other requirements of modern civilization.

STREET RAILWAY LEGISLATION.

THERE was a flocking of street railway magnates to Albany last week to argue against a number of new bills presented chiefly as the result of the report of the Nixon investigation committee. Among these measures may be mentioned bills compelling railroad companies to properly light and heat their cars; compelling 5-cent fares and transfer tickets by companies within cities; providing for the sale to the highest bidder of street railway franchises; providing that railroads be capitalized at $6,000 for each mile of road; compelling one car to stop before passing another which is at a standstill unloading passengers upon any street; compelling railroads to adopt fenders. Now, some of the bills have merit; others attempt to impose conditions governed by the local traffic and topography, and all of them taken together would easily throw an eminently solvent road into bankruptcy. Even the limitation of capital per mile has its defects. We know of one road in a minor city, where the special work within a single mile of track required a total expenditure of about $80,000 for just that stretch.

We cannot help thinking that the recent opinion expressed on many of these points by the City Solicitor of Philadelphia to the councils has the stamp of common sense on it. He said that many things complained of could be better regulated by mutual understanding than by the exercise of the power vested in the city government. The matter of heating cars, for instance, should be determined by the corporation and the public demand, inasmuch as there might be wide differences of opinion as to the best way of doing it. To require companies

also to provide a seat for each passenger would not be practicable, in his opinion, as to make this imperative would involve the corresponding duty on the part of the company to exclude a passenger from a car when all the seats are occupied, and this the public would probably object to as a great inconvenience.

ELECTRICITY DIRECT FROM COAL.

WRITERS of magazine articles, in discussing the problems in science still to be solved, never fail to refer, among other things, to the obvious desirability of obtaining light without heat and electricity direct from coal. The former of these two desiderata has of late years been actively worked at, and the results obtained are eminently encouraging, but there seems to be something repellant about the electricity-direct-from-coal problem, judging at least by the small number of experimenters who have attacked it, and the paucity of the results thus far obtained. Whether the thermopile or the electro-chemical battery will bring us to the desired end is still an open question. We have recently described what to all appearances is a marked advance in thermo-battery work—that of Mr. H. B. Cox; and this week we describe a departure in another direction due to Dr. W. W. Jacques. The salient features of Dr. Jacques' invention, and those which in our estimation give it more promise of success than its predecessors in this field, is the fact that he employs the unlimited store of atmospheric oxygen as his active agent. Others—for example, Jablochkoff, who used fused nitre, and Case, who employed chlorate of potash, depended upon the materials of the battery to furnish the required oxygen, but it will be apparent that a method by which expensive materials, rich in oxygen, are avoided, possesses advantages of prime importance, viewed from the commercial standpoint. Thus far no definite data as to the voltage or efficiency of the Jacques cell have been forthcoming, but even if the voltage is low, as is to be expected from the combination of metals employed, this need not necessarily debar the battery from many useful and perhaps extended applications, especially in connection with storage batteries, which can be charged in parallel and discharged in series for distribution.

ELECTRICAL CORPORATIONS IN MASSACHUSETTS.

SPEAKING last week in Boston before the Electric Potentials, Mr. E. W. Burdett, who has long made a special study of the subject, discussed in an able manner the legal status of electrical corporations in the State of Massachusetts. As a matter of fact, his remarks covered all corporations using the streets, though he classed the street railways by themselves and grouped all the rest together. It will be remembered that the feature of commissions plays a large part in the regulation of railway, gas, and electric lighting corporations in the State, and that these, especially since the legislation of 1894, are largely subject to government by commission. This tendency is certainly a growing one and deserves to be watched. Mr. Burdett took occasion, for instance, to point out that the Lighting Commission had far larger powers than the Railway, and it seems to us that whether in Massachusetts or elsewhere, each new commission is likely to seek or to get larger powers, until the Legislature becomes jealous of the bodies that practically exercise its delegated powers.

As we noted last week, the results in New England have been on the whole beneficial to corporations run on proper lines; and at the club meeting Commissioner Barker could rightly claim, as Mr. Burdett had willingly admitted, that his own board had met with considerable success in its work of mediation, protection and real stimulus to the industry. Most striking of all is his statement to the effect that there is a prospect of legislation by which, when a public service corporation, through no fault of its own, sustains great and extraordinary losses, it shall have the right to make that up in some proper, safe and reasonable way. This is something novel, but its intrinsic justice commends it, and it gives evidence of a kindlier feeling in the State towards progressive corporations than has hitherto prevailed.

TRADE CREDITS.

NO small credit is due to the quiet, earnest business men of Philadelphia, who came over to New York last week, and by the logic of facts convinced their fellow manufacturers and dealers in this city that it would be a good thing to stand together in the repression of the dishonest debtor. It is a wonder that something of the kind has not, indeed, been tried before. The electrical trades have grown rapidly and ramified widely. It has been easy for unscrupulous men to trap even the shrewdest seller, by shifting their accounts from one firm to another, or from one city to another, and the evil of a loose credit system has grown alarmingly. The latter days of commercial stress and trial have developed very plainly the necessity of joint dealing with the state of affairs that has arisen, and now the example of the plumbers, the booksellers and other trades will be followed, with more or less modification. The plan which the electrical leaders in the trade of Philadelphia declare to have worked well can be equally efficacious in Boston, New York and Chicago, and there should be unanimity of effort.

Quite aside from the commercial aspect of this matter, we see in it a promise of better things, as regarded from the engineering standpoint. The movement is not directed against the honest trader, nor against the competent contractor and skillful engineer. It operates rather for their protection. It makes alike for better prices and for better work. There will not be so much poor material used, and there will not be so much chance for incompetency, when the industry as a whole insists on probity in business transactions. Under the best system of prevention, the person who means to be dishonest will succeed in imposing on his creditors; but he is now apt to find his opportunities greatly limited, and everybody else will be the gainer.

ROENTGEN RAYS.

WE give space in this issue to a number of contributions relating to the theory and application of the Röntgen rays. Professor Thomson, it will be noted, makes the very ingenious suggestion of viewing the Röntgen ray pictures stereoscopically and the idea will without doubt be acted upon. From the experiments detailed by Professor Stine and Mr. Freedman, it must now be conceded that the shadow photographs obtained by means of the arc and sunlight are not X-ray pictures, or, at least, that if X-rays are present in either of these sources of illumination, they are too weak to make their presence apparent in any pictures thus far obtained.

THE VAN DEPOELE UNDERRUNNING TROLLEY PATENT.

ONE of the most far-reaching decisions was that of Judge Townsend, upholding the Van Depoele under-running trolley patent, already rendered, but a few months ago. The General Electric Company has evidently determined to test the value of this patent on all points, for, having first obtained an injunction against an operating railway, it has followed up this victory by securing another, albeit preliminary, injunction against a manufacturer of parts of the trolley gear. The decision just rendered by Judge Townsend goes so far even as to practically interdict the supply even of repair parts by outside manufacturers to railway companies originally equipped by the General Electric Company. The decision is in line with that rendered in the case involving the repair of incandescent lamps by the inserting of new filaments into the bulbs and re-exhausting them. This practice, it will be recalled, was also held to be an infringement. The cases will probably be fought out to the bitter end by both parties, and in the mean time rumors are rife of the adoption of thoroughly feasible methods and contrivances for circumventing the Van Depoele patent.

MECHANICAL.

COMPARATIVE TESTS OF SMOKE PREVENTING FURNACES.

BY B. R. T. COLLINS, ENGINEER OF TESTS, CHICAGO EDISON CO.

THE Chicago Edison Co. has in its Harrison street station two types of smoke-preventing furnaces, viz., the Hawley "down draft" furnace and the McKenzie furnace. To

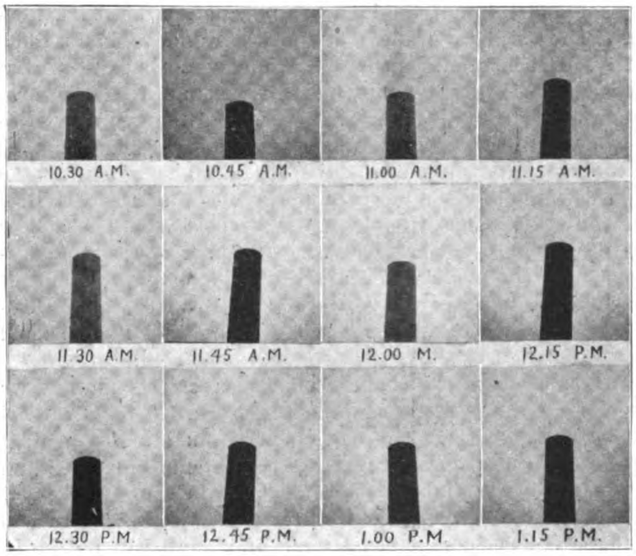

FIG. 1.—SMOKE RECORD FOR CAPACITY TEST ON MCKENZIE FURNACE, 10.30 A.M. TO 1.15 P.M. FEB. 15, 1896.

ascertain the relative efficiency of these furnaces in regard to smoke prevention, as well as their economic evaporation at varying capacities, and also the limitations of capacity under equal conditions, a series of tests were made with careful attention to details and every precaution to secure accuracy of results.

These tests were undertaken by the Edison Company for the

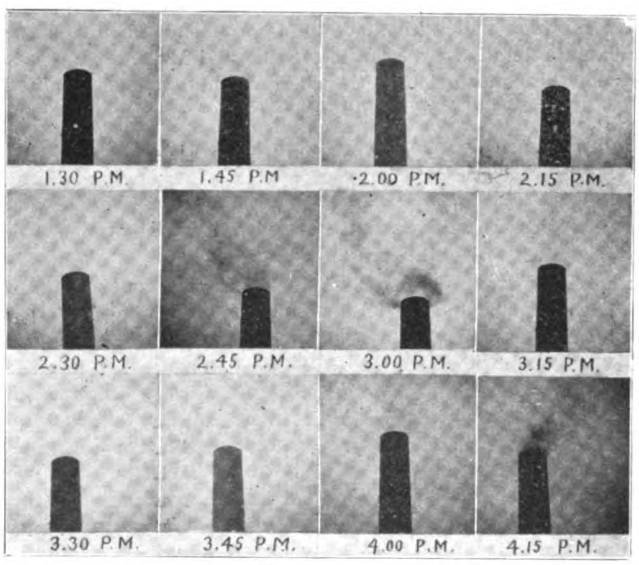

FIG. 2.—SMOKE RECORD FOR CAPACITY TEST ON MCKENZIE FURNACE, 1.30 P.M. TO 4.15 P.M. FEB. 15, 1896.

sole purpose of determining, for its own information, the relative performance of the two furnaces, but both furnace companies interested were notified that the tests were to be made and that they could have representatives present if they so desired, and such were present from both companies on all the tests. At the request of both furnace companies, made before the tests, the results are given to the public, in order to avoid incorrect statements concerning them. The conditions, methods and results are given without drawing any conclusions, leaving that to be done by those interested after all the facts have been placed before them.

Before describing the tests it might be well to mention, by way of introduction, that the Hawley furnace operates on the well-known downward draft principle in which the smoke and gases are forced to pass downward through the fire bed, formed on a water tube grate, which is necessary on account of the intense heat generated, and the carbon and gases are thus brought into a favorable condition for complete combustion, a

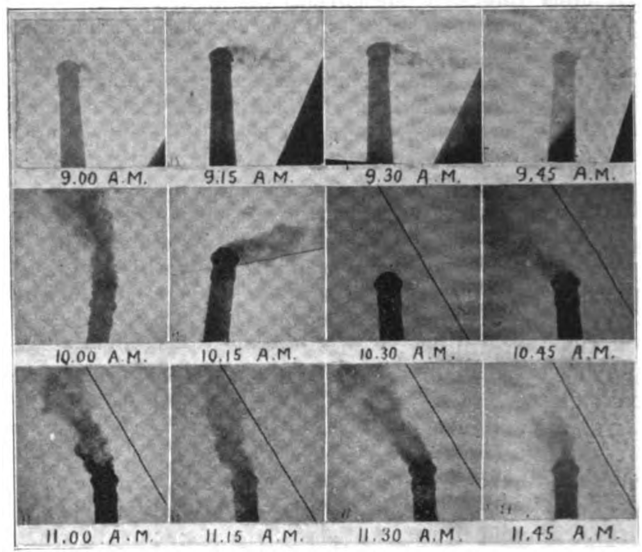

FIG. 3.—SMOKE RECORD FOR CAPACITY TEST ON HAWLEY FURNACE, 9.00 A.M. TO 11.45 A.M. FEB. 16, 1896.

lower grate being provided to receive the incandescent fuel as it falls from the upper grate. On the other hand, the McKenzie furnace operates on the entirely different principle of fire-brick columns placed beyond the bridge wall, which cause a thorough mingling of the smoke and gases and at the same time increases the heat of this mixture. Heated air is also supplied through numerous openings near the top of the bridge wall and in the sides of the above mentioned columns which

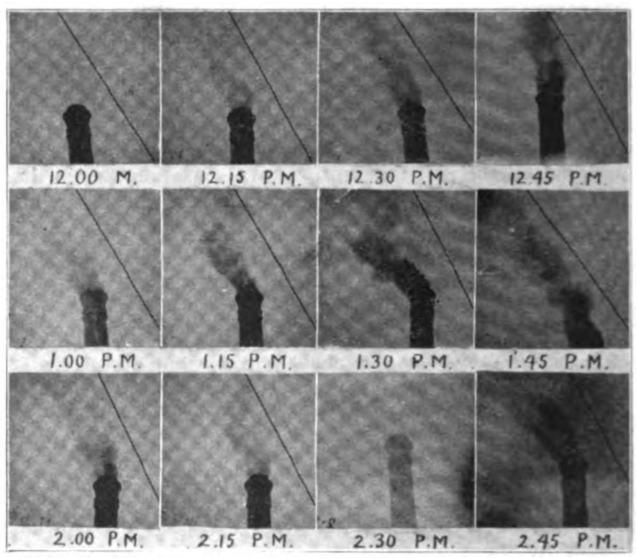

FIG. 4.—SMOKE RECORD FOR CAPACITY TEST ON HAWLEY FURNACE, 12.00 M. TO 2.45 P. M. FEB. 16, 1896.

are hollow, thus favoring more complete combustion. In addition to these there are air syphons placed in front, above the fire doors, to supply air and effect a thorough mingling of the air, gases and carbon, thus aiding combustion. These, briefly, are the principles involved in the furnaces tested.

The Hawley furnace tests were made on boiler No. 1, which

is a Heine safety boiler, rated at 500 horse-power capacity on the Heine basis, which is obtained by dividing the equivalent evaporation from and at 212 degrees Fahrenheit by 31 lbs. This basis, however, has no foundation in reason, as the commercial horse-power of a boiler is obtained by dividing the equivalent evaporation from and at 212 degrees Fahrenheit by 34.5 lbs., which is used by all other boiler-makers except the Heine Company; but as the boilers are rated on this 31-lb basis, this has been used in determining the horse-power developed in the results given below. Boiler No. 1 has two 42-inch shells, 19 feet 9½ inches long, 241 3½-inch tubes, 16 feet long, 3,800 square feet heating surface and 65 square feet upper water tube grate surface.

The McKenzie furnace tests were made on boiler No. 8, which is a Heine safety boiler of the same dimensions as No. 1, except that it is two rows of tubes higher (37 tubes), making 278 3½-inch tubes with a heating surface of 4,340 square feet, which, at the same rating (7.6 square feet per horse-power) would be a capacity of 571 horse-power, but this is hardly fair to the boiler, as the additional tubes probably have only 50 per cent. of the efficiency of the average tube. However, with this explanation it will be taken at 571 horse-power capacity.

In this connection it should be remembered that the water tube grates of the Hawley furnace add to the heating surface of the boiler, but are not considered as increasing its rated capacity.

The stack to which No. 1 is connected is 185 feet high above the grate bars, giving about 1 inch of draught, whereas the stack for No. 8 is only 102 feet 8 inches high, giving but ½ inch to 9-16 inch draught; consequently to make the conditions equal, so as to admit of comparison, the damper at the base of the tall stack was lowered until the same draught was obtained in the breeching over No. 1 boiler as existed in the breeching over No. 8 boiler, and these conditions were maintained during the respective comparative tests.

Following are some of the details of the methods used in making the tests: The fires were cleaned half an hour before the beginning and end of each test and at equal intervals during the test as was found necessary. The boilers were run at about the same rate as during the test for several hours previous to starting the test and were thus thoroughly heated. The coal was weighed by the barrowful, in lots large enough for about one hour's firing. The ash chutes were cleaned out on starting and stopping the test, and ashes accumulating during the time of the test carefully weighed. The conditions as to kind of fire, amount of coal on the grates, height of water level and gauge pressure were noted at the beginning of each test and obtained as nearly as possible at the close, the water level and gauge pressure being maintained as constant as possible throughout the test. The water used for these tests was taken from the hot well and weighed by means of two tanks on scales of an average capacity of about 900 lbs., these tanks discharging into a reservoir from which the test feed pump took its supply and discharged it through an independent feed line to the boiler being tested. All of the valves leading off of this line were tightly closed and sealed with wax and examined after the tests, all being found intact. All of the scales used for weighing coal, ashes, and water were tested and adjusted to read correctly. The temperature of the escaping gases was taken in the uptakes just below the dampers by a thermometer reading to 800 degrees Fahr. The draught was taken by a draught-gauge connected to a pipe extending about 3 feet into the breeching above the boiler. The atmospheric pressure was taken from an aneroid barometer, compared and corrected by a mercurial barometer.

The moisture in the steam was found to be very small on boiler No. 1, but on account of difficulty in making a proper connection on boiler No. 8, it was neglected in the results on both boilers. The calorimeter used was of the throttling type designed by the writer and used on a large variety of tests with uniformly satisfactory results.

Each boiler was thoroughly washed and put in the best possible condition just previous to the tests, the flues being blown two hours previous to the start of the test in each case. The steam gauge used was tested and corrected, and transferred from one boiler to the other for each test. The blow-off pipes were plugged in each case and in the case of boiler No. 1, where the connections were not tight, the drip was collected and weighed back.

The coal used on all the tests was Auburn screenings from the Sugar Creek Mining Company's mines, which are situated about fifteen miles south of Springfield, Ill., or 200 miles south of Chicago. The tests of Feb. 2 and 3 were made with coal from the same car to insure uniform quality as far as possible, as were also the tests of Feb. 15 and 16. The firing on the Hawley test of Feb. 2 was done by the expert fireman of the Hawley Company, and that on the McKenzie test of Feb. 3 by one of the regular head firemen of the station. On the capacity test of the Hawley furnace the firing was done by two expert firemen of the Hawley Company, and on the capacity test of the McKenzie furnace, by a regular head fireman of the station and an assistant.

In weighing water and coal, regulating the water level, taking all of the observations and keeping all of the records necessary on tests of this kind I was assisted by a trained corps of six assistants, who have performed similar duties in connection with the large number of tests of various kinds which have been made at Harrison street station during the past two years, thus insuring in a large degree the accuracy of the results obtained.

The smoke record was kept by means of instantaneous photographs taken at fifteen-minute intervals throughout each test by the official photographer of the Edison Company. The records of the capacity tests of Feb. 15 and 16 are reproduced in full, while the record of the economy tests of Feb. 2 and 3 is omitted, as it shows only very small amounts of smoke. It should be stated here that boiler No. 1, used on the Hawley furnace tests, was equipped with three fire-brick arches four feet long at the bridge wall through which all the gases had to pass. These were put in by the Hawley Company as an additional device for smoke prevention when the fires were

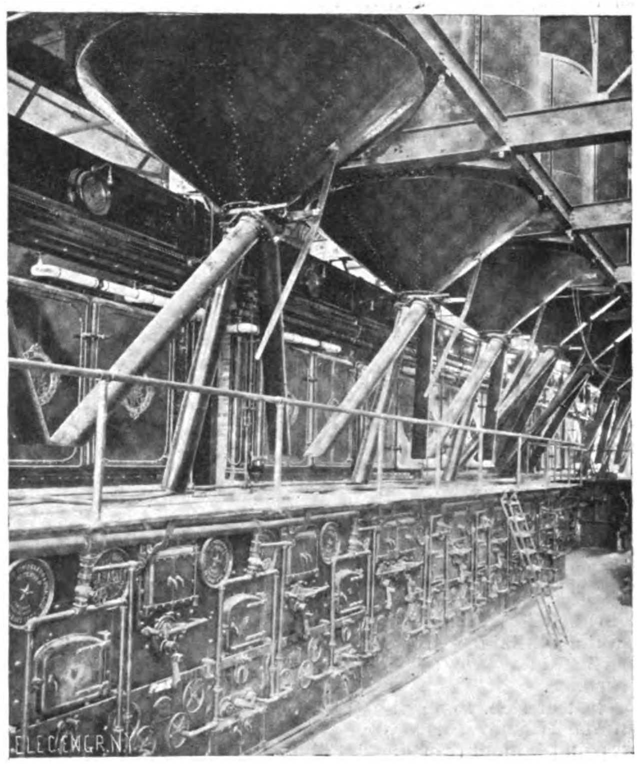

Fig. 5.—Boiler Room, Chicago Edison Co.

being forced. The boiler being tested, was the only boiler using the stack at the time of the tests, in order to obtain a record of the smoke from one boiler only.

The tests of Feb. 2 on the Hawley furnace and of Feb. 3 on the McKenzie furnace were made for most economic evaporation, the basis of comparison being equal amounts of coal burned per square feet of grate surface with equal draught. The coal burned was limited to 31 lbs. per square foot of grate surface, as this had been found to give the best results on the Hawley furnace, judging from a series of 25 or 30 tests made on that furnace at the station during the past year with different kinds of screenings. The results in detail are as given in Table 1.

From this table it will be seen that the Hawley furnace shows .19 lb greater actual evaporation, or 3.16 per cent.; .26 lb greater evaporation from and at 212 degrees Fahr., or 3.71 per cent.; 10 horse-power less capacity, but on account of difference in rating, 10 per cent. greater proportion of capacity developed; 2.1 per cent. greater efficiency; 40.4 degrees Fahr., or 5.85 per cent. lower flue temperature; 3.9 per cent. greater proportion of ash, and \$0.002, or 2.82 per cent. less to evaporate 1,000 lbs. of water than the McKenzie furnace.

The amount of steam used in the air syphons of the McKen-

zie furnace was determined by condensing the steam issuing from the steam orifices under the same conditions as during the tests and obtaining its actual weight. The mean of three experiments gave 315 lbs. of steam per hour, or 2.16 per cent. of the evaporation of the boiler from and at 212 degrees Fahr. Taking this into consideration the water evaporated per lb. of coal from and at 212 degrees Fahr. would be reduced from 7

TABLE 1.

COMPARATIVE TESTS FOR ECONOMIC EVAPORATION.

	Hawley.	McKenzie.
Date of trial	Feb. 2, 1896	Feb. 3, 1896
Duration of trial ... hours	8	8
Dimensions and Proportions:		
Number and diameter of tubes	241-3½" × 16'	278-3½" × 16'
Grate surface ... area, sq. ft.	65	68.6
Water heating surface ... sq. ft.	3,800	4,430
Ratio of grate surface to heating surface	1 to 58.5	1 to 63.3
Chimney dimensions, height and diameter	185' × 13'	102'-8" × 8'-10"
Force of draught ... inches of water	0.5	0.5
Average Pressures:		
Steam in boiler, by gauge ... lb	169.6	171.8
Atmosphere, by barometer ... lb	14.3	14.1
Absolute pressure ... lb	183.9	185.9
Average Temperatures:		
Of feed water entering boiler ... deg. F.	95.0	100.4
Of flue gases at uptake ... deg. F.	649.6	690.0
Fuel—Kind of Coal—Auburn Screenings:		
Cost per ton of 2,000 lb, delivered	$1.00	$1.00
Calorific power by analysis—B. T. U. per lb	11,912	11,912
Theoretic evaporative power, from and at 212° F., in lbs. water, per lb coal	12.33	12.33
Total quantity consumed ... lb	16,065	17,027
Total ash, clinkers and unburned coal ... lb	2,426	1,907
Proportion of ash, etc., to coal ... per cent.	15.1	11.2
Combustion Per Hour:		
Coal actually consumed ... lb	2,008	2,128
Coal per sq. ft. grate surface ... lb	30.9	31.0
Coal per sq. ft. heating surface ... lb	.528	.490
Water:		
Amount apparently evaporated ... lb	99,514	102,024
Factor of evaporation	1.173	1.168
Equivalent evaporation from and at 212° F.	116,730	119,164
Economic Evaporation—Per Pound of Coal:		
Water actually evaporated ... lb	6.19	6.00
Equivalent from and at 212° F. ... lb	7.26	7.00
Evaporation Per Hour:		
Water actually evaporated ... lb	12,439	12,753
Equivalent from and at 212° F. ... lb	14,591	14,895
Per sq. ft. heat. surf.—actually evap. ... lb	3.27	2.94
Equivalent from and at 212° F. ... lb	3.84	3.43
Per sq. ft. grate surf.—actually evap. ... lb	191.4	185.9
Equivalent from and at 212° F. ... lb	224.5	217.1
Efficiency:		
Per cent. of total calorific power utilized	58.9	56.8
Water evap. for $1 worth of fuel ... lb	14,520	14,000
Cost of evaporating 1,000 lb of water	$0.069	$0.071
Coal consumed per H. P. per hour ... lb	4.26	4.42
Cost of same	$0.0021	$0.0022
Horsepower:		
Actually developed on Heine basis of 31 lb water evap. per hour from and at 212° F.	471	481
Heine rating ... horsepower	500	571
Proportion capacity develop'd, rating ... %	94.2	84.2
Heating surface to develop I.H.P. ... sq. ft.	8.07	9.02

lbs. to 6.85 lbs, available outside of the boiler, which would make the available evaporation from and at 212 degrees Fahr., shown by these two tests, 5.99 per cent in favor of the Hawley furnace.

The test of Feb. 15 on the McKenzie furnace and that of Feb. 16 on the Hawley furnace were made for maximum capacity with equal amount of draught; the amount of coal to be burned being unlimited in order to determine the maximum amount of this particular coal that could be burned by each furnace under equal conditions.

The tests for economic evaporation were eight hours in duration, but it was considered that six hours of forced firing would be long enough to obtain a fair average, hence the tests for capacity were six hours long. On Feb. 15, after running a little over an hour an attempt to clean the fires was made, when it was found that, owing to the peculiar condition of the fire, the grate bars were completely covered with a hard metallic clinker which required half an hour to remove, and during this time evaporation was almost completely checked, hence for the sake of fairness, the test was recommenced at the beginning of the next hour and continued for six hours thereafter.

On the test of Feb. 16 the coal, which was taken from the same car as that used on the 15th, was exhausted and hence two barrows of coal from another car had to be taken to finish out the test. The results of the capacity tests are given in Table 2.

From the results in Table 2 it will be seen that the McKenzie furnace shows .74 lb., or 14.0 per cent greater actual evaporation; .18 lb., or 13.4 per cent. greater evaporation from and at 212 degrees Fahr.; 23.4 horse-power greater capacity, but on account of difference in rating 8.6 per cent. less proportion of capacity developed; 7.3 per cent. greater efficiency; 52.9 degrees Fahr., or 8.12 per cent. higher flue temperature; 1 per cent. great proportion of ash, and $0.01, or 12.3 per cent. less to evaporate 1,000 lbs. of water than the Hawley furnace. Taking into consideration the steam used in the air syphons, which was 2.16 per cent., as stated above, the available evaporation for use outside of the boiler would be 6.87 from and at 212 degrees Fahr., which would make the available evaporation

Heating surface to develop 1 horse power ... sq. ft.	8.15	7.47

from and at 212 degrees Fahr., 10.99 per cent. in favor of the McKenzie furnace.

These tests also show that 39.23 lbs. is the maximum amount of this particular coal that can be burned by the Hawley furnace, with 9-16 inch draught, per square foot of grate surface per hour. Under the same conditions the maximum limit of the McKenzie furnace is 34.26 lbs., which is 4.97 lbs., or 14.5 per cent. less than the Hawley furnace, but the double grate of the latter should be taken into consideration in this connection.

A POWER PLANT IN MARIPOSA COUNTY, CAL.

Mariposa County, California, is to have one of the largest electrical power developing and distributing plants in the United States. It will be at the Horseshoe Bend, on the Merced River. The location is near the center of a mining district, having at least 100 mines that are sufficiently prospected to use cheap power. At the driest season of the year the power company calculates upon 1,800 horse-power, and during eight months in the year they expect water enough to generate 3,500 horse-power. The price the company proposes to charge its customers is $5 per horse-power a month. At the present time the expense of producing steam is from $12 to $15 per horse-power, and two years hence, at the present rate of consumption of cordwood, the hills would be bare of timber, and steam power, except in a few localities, at a price almost prohibitive.

THE ELECTRIC light installation in the handsome building of the Duquesne Club, Pittsburg, will be a complete one in every respect. "Ball" engines, built by the Ball Engine Company, Erie, Pa., direct connected to Westinghouse dynamos, furnish the light and power.

STRATTON COMBINED SEPARATOR AND STEAM RECEIVER.

THE fall of pressure that takes place between the boiler and the engine, due to the fact that the volume of steam necessary for one stroke of the engine has to be drawn from the boiler through a long and sinuous pipe during the short period of admission which in an ordinary Corliss engine is only one-fifth to one-quarter of the stroke, has always been a source of annoyance to engineers. This reduction of pressure, as shown by indicator cards, generally amounts to from 5 to 10 per cent. of the boiler pressure.

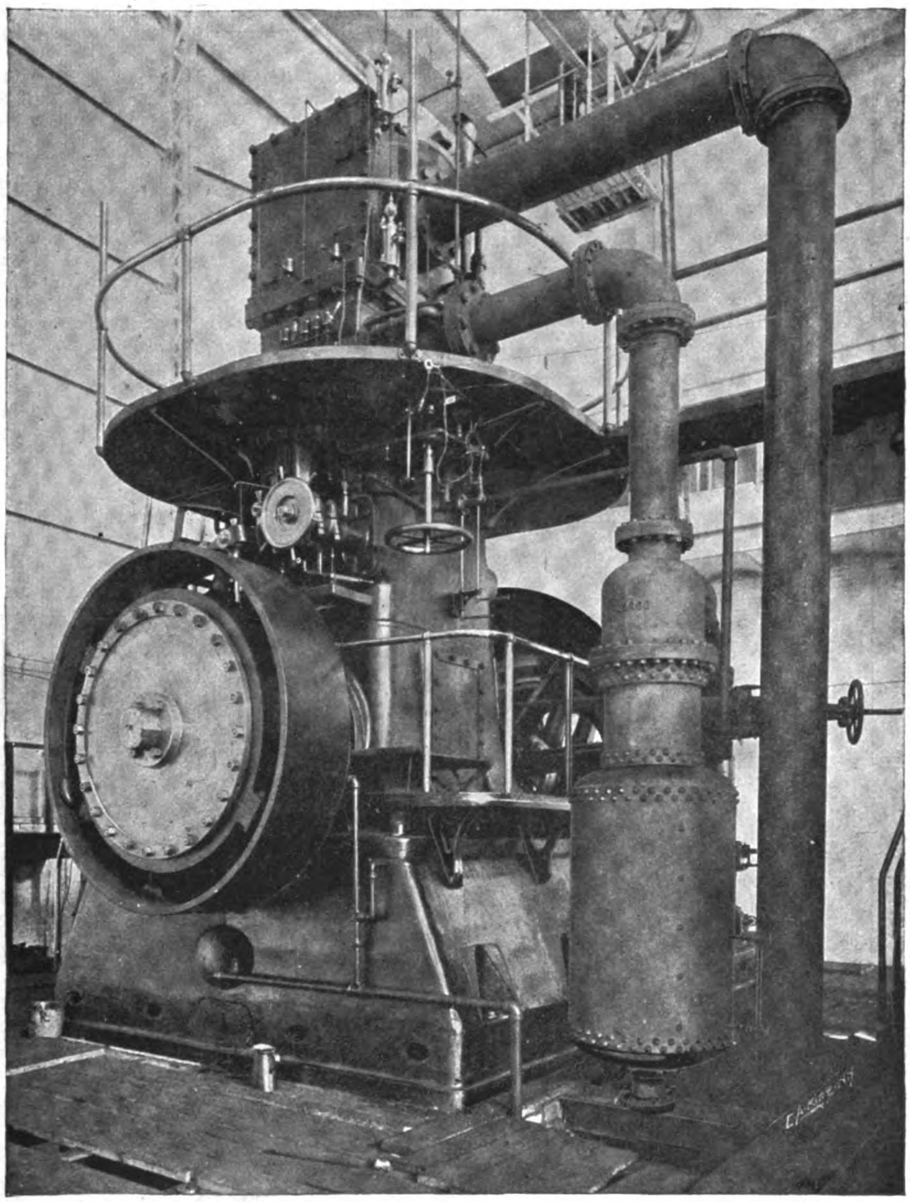
Using very large steam pipes reduces the loss only in a measure, while open to the objection of increased cost, greater difficulty in keeping the joints tight, especially under high pressures, and greater liability to accidents; steam pipe explosions having unfortunately been too frequent of late.

In view of all this it has become the practice in large plants to place a large reservoir or receiver close to the engine; thus insuring a free supply of steam at substantially full pressure during admission, the boiler having ample time during expansion to again restore the pressure in the receiver.

A receiver of this kind for high pressures has to be specially designed and exceedingly well made. Its construction cannot be entrusted to any ordinary boilermaker; as it is an engine-room appliance nicely covered and lagged, the slightest leak must be avoided.

All these considerations have led the Goubert Manufacturing Company of New York, manufacturers of the Stratton steam separator, to design a combined separator and steam receiver. The making of the two appliances in one, while insuring a supply of perfectly dry steam at full pressure to the engine, economizes space and makes a much neater appearance, as well as lessening the number of joints that would be necessary if two different apparatuses were used. The large experience and manufacturing facilities of this company for high-pressure work are a guarantee that nothing but good and tight work, with a safe and efficient apparatus will be furnished.

The Goubert Manufacturing Company have already supplied these combined separators and receivers to a number of large power plants. Among them may be mentioned the United Electric Light and Power Company of New York, West End Railway Company of Boston and Nassau Electric Railroad Company of Brooklyn.



STRATTON COMBINED SEPARATOR AND STEAM RECEIVER.

The accompanying engraving shows one of four of these Stratton combined separators and steam receivers connected to 1,200-horse-power Westinghouse engines at the new power house of the United Electric Light and Power Company, East Twenty-eighth street, New York City. The following extract from a letter to the Goubert Company from the chief engineer of the United Electric Light and Power Company, Mr. H. W. York, may prove interesting:

"The form of combined separator and receiver furnished by you for the Twenty-eighth street station of this company has proven most satisfactory in every respect.

"The separators remove practically every trace of entrained water, while the receivers keep a constant supply of steam right at the throttle, which is not affected in pressure by the pulsations of the engine to an extent of over one-half of one per cent.

"I have made several tests to ascertain the drop in steam pressure between the boilers and the receivers, and even when the engines are loaded I cannot find any appreciable drop. In making these tests I have used two indicators, which were first placed on the steam pipe, side by side, and ascertained to be precisely alike; then one placed on the separator and one on the steam header in the boiler room. Cards were taken from these indicators at the same instant, and after the experiments were completed the indicators were again calibrated and found to agree. In all these tests the difference in steam pressure at the two points was scarcely discernable.

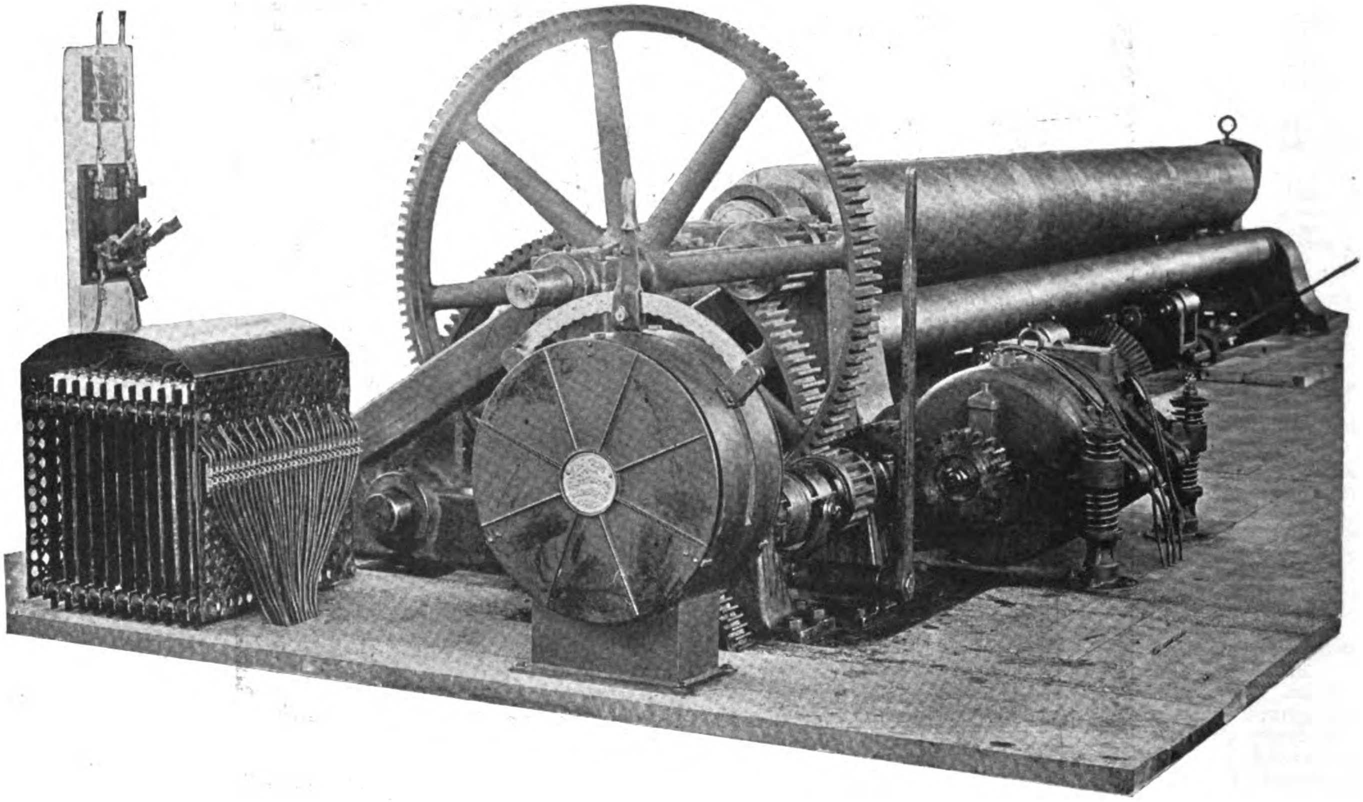
"I may also add that in consequence of maintaining a constant pressure at the engine there is practically no vibration in the steam pipe."

POWER TRANSMISSION.

BENDING ROLLS OPERATED BY THE CARD SERIES REVERSIBLE MOTOR.

THE accompanying engraving shows a 30-horse-power series reversible motor, controller and rheostat attached to bending rolls capable of bending iron plates 20 inches long by ¼ of an inch or more in thickness. The electrical apparatus illustrated in connection with the bending rolls is manufactured by the Card Electric Company, Mansfield, Ohio.

The motor is of 30-horse-power capacity, at a speed of 325 revolutions per minute under full load. It is geared direct to a shaft, carrying a clutch, which is operated by a vertical lever, which engages in two trains of gearing, as desired; one for revolving the two lower rolls and the other for raising and lowering the upper one. As the motor is reversible, the manipulation of the rolls for bending plates on any circle is easily and quickly accomplished, and with great accuracy. The rheostat is made up of iron wire in an improved form, and has a capacity to carry the full current of the motor under all loads and at any speed. The resistance is sufficient to permit reversing the motor at full speed and under all conditions. The controller is particularly adapted and arranged for series-wound motors, where close regulation of speed, sudden stops and quick reversals of motor are required. All the working parts are made amply large on account of the severe work necessarily required of such apparatus. The circuit is opened at twenty-four contacts, breaking in unison, reducing the spark to practically nothing. Twenty-nine contacts are provided for regulating the speed. By means of this construction any desired speed can be had and maintained. The resistance being so subdivided and the contacts so arranged for cutting portions of it in or out that arcing over and blistering the contacts is impossible.



CARD MOTOR DRIVING PLATE BENDING ROLLS.

POWER TRANSMISSION IN THE INDIAN TERRITORY.

The Purcell Electric Light and Water Company, Purcell, I. T., has quite recently put in a plant for local work and is now putting in wires and poles for operating at Lexington, O. T., in connection with the same plant. Current will be carried a considerable distance, at one point crossing the Canadian River some 4,080 feet from bank to bank. The officers of this enterprising company are J. Taylor Bradley, T. W. Brannon, and W. I. Brannon.

THREE-PHASE PLANT IN A SOUTHERN COTTON MILL

The electrical equipment of the extensive cotton mills of the Pelzer Manufacturing Company, one of the largest cotton goods manufacturing concerns in the South, is rapidly nearing completion. The motive power is derived from Victor turbine water wheels, driving three 750 kilowatt three-phase generators, wound for 3,300 volts. The water wheels turn at a speed of 164 revolutions per minute.

The electricity generated at the power house will be carried a distance of three and a half miles to Pelzer, where it will enter the mills and drive the following motors: One 400 h. p. synchronous motor wound for high potential and several multi-phase motors of varying capacities from 5 h. p. up to 110 h. p. The majority of these motors will be of the inverted type, suspended from the ceiling in the different rooms. They will receive the current at a low potential from step-down transformers, placed in the substation at the mills. The mills will also be lighted from the same circuit.

The system utilized in the operation of these mills is the three-phase system, developed by the General Electric Company. It is the same system in use at the Columbia mills at Columbus, S. C., and at the Ponemah Mills at Taftville, Conn.

MISCELLANEOUS.

THE BALDWIN ELECTRIC METER.

NOTHING is so comforting to a station manager as the knowledge that his customers' meters are accurate, in the first place because it insures the proper income for the station output, and secondly because it removes the annoying complaints of overcharge by customers.

The Baldwin Electric Meter Company, of Washington, D. C., have just placed on the market a recording electric meter, of decided novelty, which is claimed to possess in a high degree the valuable qualities of reliability and accuracy. The meter is

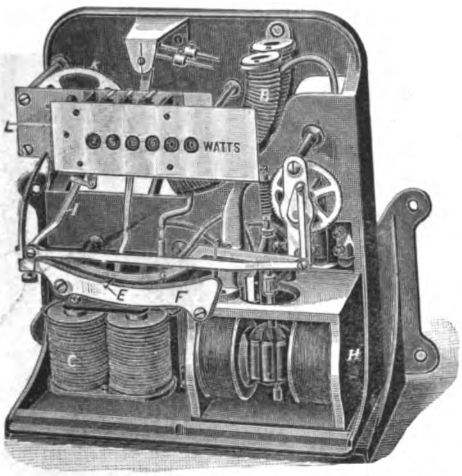


FIG. 1. THE BALDWIN ELECTRIC METER.

constructed so as to cut itself in circuit on one lamp, and to register that one lamp with as much power and certainty as its full capacity of lamps. It can also run slow or fast, above the normal speed or below the normal speed, and yet the current consumption can always be read with positive accuracy within 1 per cent.

Our engraving, Fig. 1, shows the construction of the meter. The current enters at the binding post A, and traverses the solenoid B, and cut-out C, and then takes its exit at the binding post D. The solenoid operates in the usual way to swing a fulcrum pointer E, whose zero point is at the left hand end of the backing plates F. Above this fulcrum pointer is a cam-shaped lever G, whose right hand end is reciprocated periodically by the motor and crank movement,

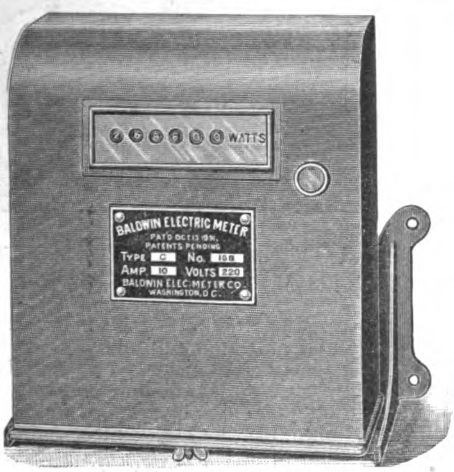

FIG. 2. THE BALDWIN ELECTRIC METER.

and whose left hand end is connected by the connecting rod I, to the ratchet wheel K.

When one or more lamps are turned on the circuit, the armature of the cut-out, C, shown at hte botom, is brought down on its contact, thus putting in circuit and starting at full power the motor H, the fulcrum E also at the same time moving forward, taking position further and further to the right as more and more current is turned on the circuit. The binding post, near cut-out C, connects with one side of the circuit and the spring contact through the motor with the other side.

As the cam lever G, is reciprocated by the crank movement, it strikes the fulcrum pointer, which is bent down until supported by the backing plates F, and the left end of the cam lever is lifted up by the connecting rod I, which movement is communicated to the ratchet wheel and registered on the counter L.

It will be seen that the more current on the circuit the further to the right the fulcrum pointer takes its position and the greater will be the movement of the cam lever and the greater the rotation of the ratchet wheel. The cam lever is so designed as to give rotation to the ratchet wheel proportional to the current passing through the meter, and great accuracy is obtained throughout the whole range and capacity of the instrument. When the cam lever is in its uppermost position, the fulcrum pointer touches no part of the instrument and it is perfectly free to take up a new position which indicates a change in the current strength.

The motor H has power greatly in excess of its required work, being an efficient and well constructed iron motor. Although taking but 7-100 ampere, it always runs at its full power, has good brush contact on the commutator, and maintains its speed very close to the normal, being connected independently directly across the mains. For any motor speed accurate readings of current consumption may always be had by taking the motor speed in the following way: The normal crank speed is 3 revolutions per minute or 5 revolutions in 100 seconds, and if 5 revolutions of the crank are timed and it is seen that such 5 revolutions take place in 105 seconds, the motor is running just 5 per cent. slow, and 5 per cent. should be added to the counter reading for obtaining an accurate result. If the crank should show 5 revolutions in 97 seconds, the motor is running 3 per cent. fast and just 3 per cent. should be subtracted from the reading of the counter in order to obtain the true final consumption of current. Great accuracy is thus obtained for any motor speed.

The meter has a slow speed motor, making 300 r. p. m., and requires little attention; it is very economical since no current is consumed in the meter itself when no lamps are on the circuit. The meter shown in the cut is for the two-wire direct current system, and the three-wire meters are constructed in the same way with two solenoids. The engraving, Fig. 2, shows the meter enclosed in its protecting case.

THE GENERAL ELECTRIC CO.'S EXHIBIT AT ATLANTA.

THE central space in Electricity Building at the late Atlanta Exposition was occupied by the compact and well-arranged exhibit of the General Electric Company, illustrating the latest developments in the fields of electric lighting, railway and power.

The exhibit, which is illustrated in the accompanying engraving, was erected on a raised platform surrounded by a cornice supported on columns of white enameled iron. The cornice was decorated with a row of miniature purple lamps breaking into groups of amber lights over the caps of the posts. The side of the cornice facing the exhibit was ornamented with a line of frosted lamps.

The railing was an exhibit in itself, made of lengths of one-inch brush-holder cable, stretched between standard insulated railway turnbuckles. It was supported on posts capped with General Electric insulators. At the ends of the platform the place of the cables was taken by nickel-plated trolley wires supported on high tension porcelain insulators of the double-petticoat pattern, similar to those used for the Sacramento-Folsom plant. The roof of the office, which stood in the center of the space, was decorated with a large model of an Edison lamp socket, three feet high, in the construction of which not less than 700 standard sockets were used.

The office stood under an arch—one of the most interesting features of the exhibit. It was a model of the upper field of one of the large 800 k. w. monocyclic generators now running in the station of the Edison Illuminating Company, St. Louis, Mo. The model is full size, 21 feet in diameter. These generators are the largest that have ever been constructed and operated. As erected here, the armature could be set upon the floor and just fit the field frame in its present position. The supports for this model were two large pyramids, the four sides of which formed display boards on which were artistically arranged fine selections of the many lines of railway, power and lighting supplies made by the company.

While the visitor was impressed with the model of the great monocyclic generator field, an opportunity was also afforded him in viewing the monocyclic system itself in actual operation. A monocyclic generator of 250 k. w. capacity ran day and

night in Machinery Hall and supplied current for the illumination of a large portion of the halls and buildings, as well as for the operation of 30 and 50 h. p. induction motors. The visitor was thus enabled to judge of the flexibility of the system from personal observation.

One corner of the exhibition space was occupied by a 30 horse power three-phase induction motor driven by current from the monocyclic generator just mentioned. The motor is started by the closing of a switch and comes to full speed quickly. This motor drove a 20-kilowatt, 125-volt, four-pole, slow-speed generator, furnishing current to illuminate two signs, each forty feet long, conspicuously hung below the balconies opposite each end of the exhibit. The name of the General Electric Company was spelled in eight-candle-power lamps and stood out prominently in neat white script against a black ground.

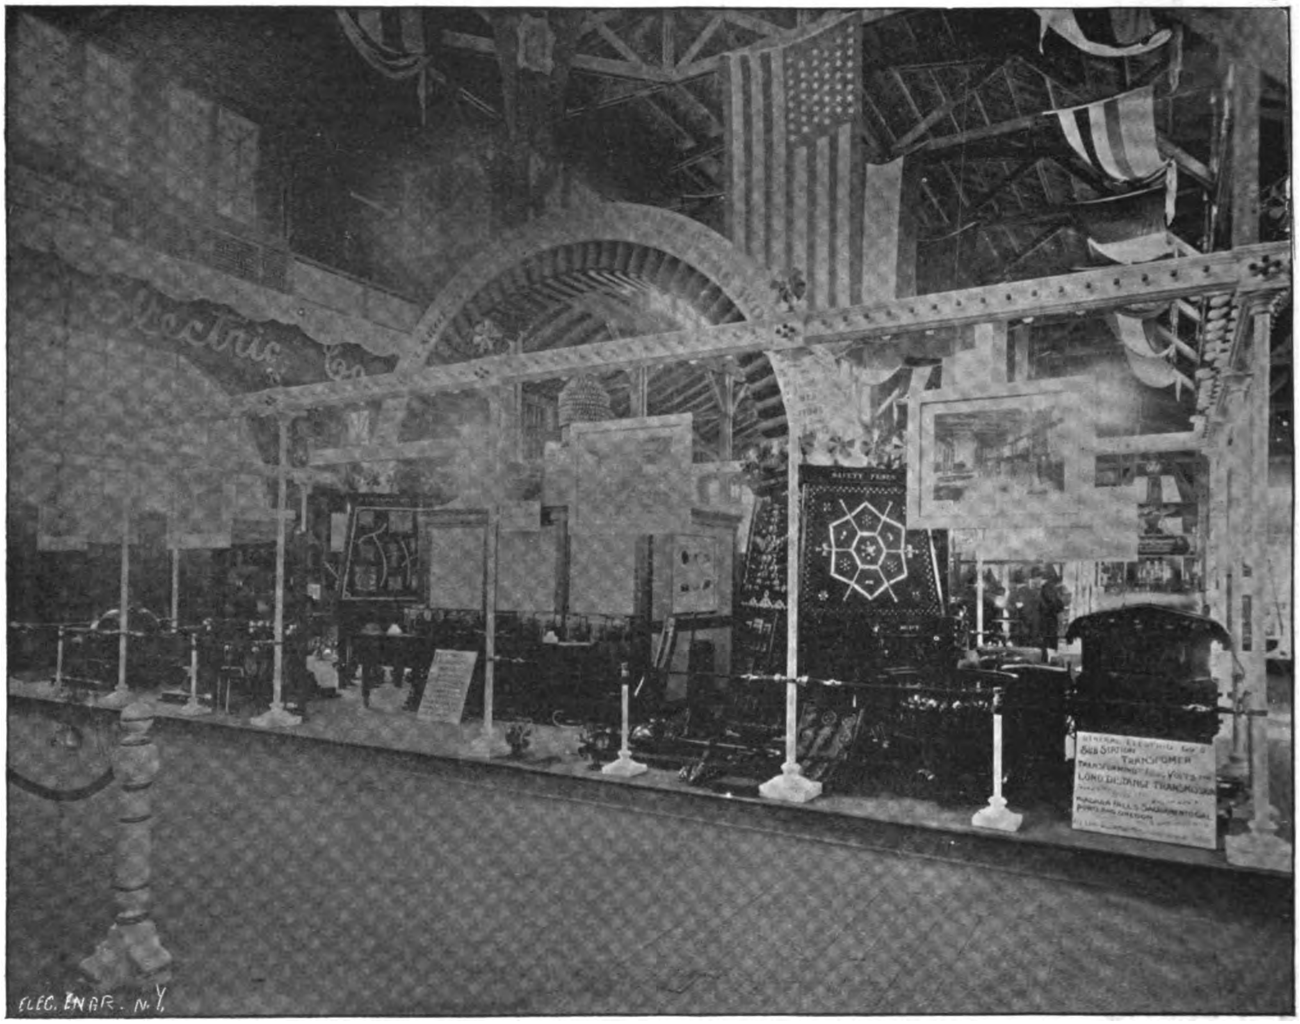
A full set of the latest type, plain and ornamental, arc lamps for incandescent circuits were shown hanging from a stand of wrought iron scroll work. Several arc lamps intended for use, ten in series, on 500-volt railway circuits, were also shown. This display of arc lamps also included the alternating current arc lamp, reported to be meeting with success throughout the country. The arc lamp exhibit was further increased by a full display of the apparatus and devices necessary in arc light service.

The marine work of the General Electric Company was represented by a small plant, consisting of an engine and a generator, directly connected, and a switchboard adapted to marine requirements. The complete plant illustrated the compactness necessary in all electrical work on shipboard.

One corner of the space was devoted to railway appliances, including, of course, the trio of G. E. motors; the G. E. 800 for ordinary street car service, the G. E. 1,200 for suburban service and the G. E. 2,000 successfully used on electric elevated roads and those branches of steam lines fortunate enough to have adopted electricity. Car controllers of the well-known "K2" style were shown, together with a large "L" controller, designed for use with the G. E. 2,000 motor. A well-arranged panel switchboard with full equipment of automatic circuit breakers, quick brake switches, indicating and measuring instruments rounded off the railway exhibit.

The line of transformers was represented by a sample of each size, from the small 350 watt transformer for six lights to the 30,000 watt transformer for 600 lights. A 250 k. w. transformer of the air blast type was also shown. This type of transformer has been introduced for sub-station work to transform up to, and down from, very high voltages in long-distance transmission work. Many are now in successful use at Portland, Ore., Sacramento, Cal., Niagara Falls, N. Y., and Lowell, Mass.

Samples of wire and cables made by the company in its works at Schenectady were shown in mahogany cases, and the system of underground tubes, used in Boston, Chicago, New York and other places, was exemplified by many fine samples of tubes, conductors and subsidiary appliances.



THE GENERAL ELECTRIC COMPANY'S EXHIBIT AT THE ATLANTA EXPOSITION.

(To be repeated at the New York Electrical Exposition.)

Thomson recording wattmeters occupied a small department by themselves and every size was shown, from the smallest to the largest, including some fine samples of the large station meters which record an output as high as 8,000 amperes. Samples of fan motors, small bi-polar generators and motors with cylindrical field frames were also exhibited.

Hung around the exhibit were a number of enlarged photographs, illustrating the work done by the General Electric Company. Each enlargement was framed in white and an examination of these pictures alone would give an excellent idea of the extent of the General Electric Company's factories, as well as the important installations throughout the country in which its apparatus is used. From these pictures the visitor also gained a good idea of the recent developments in electrical practice, as the photographs included the interior of the Portland (Ore.) power station, the conduit railway system on Lenox avenue, in New York City, the Nantasket Beach (Mass.)

road, the elevated roads in Chicago, and the great electric locomotives now operating on the Baltimore and Ohio Railroad.

In addition to the exhibit in Electricity Building some standard machines were in operation in Machinery Hall. These included the monocyclic generator, already referred to, a single-phase alternator, a Thomson-Houston arc machine, and a large bi-polar generator.

The searchlights on the roof of Machinery Hall and on the tower of the Government Building, the lamps which operated the electric fountain and its complete electrical equipment, the Tower of Light which floated in splendor on the lake, were all parts of the comprehensive exhibit of the General Electric Co.

The following awards were made to this company: Two gold medals for (1) photographs and description of the Baltimore and Ohio locomotive and (2) generator, motors and lamps operated by the monocyclic system; 6 silver medals for (1) T.-H. arc light system; (2) T.-H. alternating light system; (3) Edison lighting system; (4) street car system; (5) Thomson recording wattmeter; (6) Brush arc light system. Honorable mention for (1) portable alternating measuring instruments; (2) direct connected marine set; (3) searchlights; (4) insulated wires and cables.

ELECTRIC HEATING.—III.[1]

(Concluded.)

BY W. S. HADAWAY, JR.

The car heating tests made show that with the use of about four horse power the interior of the car can be kept practically at 50 degrees F. From one point of view this is too low a temperature for comfortable passage. And yet if the heater is devised to deliver a part of its energy to the floor of the car, to keep it warm and dry, and about the limbs of the passengers, this is high enough for practical purposes. The problem of car heating practically resolves itself into providing a form of foot warmer heated by electricity and used for effective warming rather than for heating per se.

On the Esquimaux plan of huddling together for warmth, a car can be kept at about 40 degrees F. by animal heat; each adult passenger gives off 190 heat units per hour, or 14 passengers will give off as much heat as one electrical horse power hour. There are cases in practice in which the animal heat on some runs is practically the equivalent of the electrical energy used in heating. Clearly, then, the proper use of electrical energy is on the basis of individual effectiveness rather than for heating as commonly understood.

Using the methods commonly employed for computing the heat necessary for warming, a 20-foot car requires eight horse power hours to keep it at 65 degrees with the outside air at zero. In the cars examined in use the energy supplied for heating by electricity was about equal to the loss from glass radiation. There are cases in which the energy used for heating by electricity is 40 per cent. of the energy used in operating a particular car. And yet, assuming that five horse power is a fair average for use, the cost is about $10 per month per car for heating, or about 33 cents per day or 2 cents per hour. The use of five horse power is a high one for effective warming, as it would heat 37 square feet of radiating surface to 185 degrees with the car at 50 degrees, while with the best systems of radiation for complete diffusion yet suggested the surface available is about 30 square feet, requiring four horse power to heat.

While most of the electric car heaters now supplied do not meet the conditions here imposed, the fact that several thousand cars are equipped with and are using the heaters attests their value. I beg to quote in this connection from a letter written me by a well-known street railway expert:

"I think that the decision for or against heating in any particular case will have to be given with the distinct understanding that collateral advantages and not coal economy form the real criterion. You will remember that I spoke to you about a large plant which had been using heaters this winter with a very great expenditure of power. I had a talk with the manager a few days ago with the following results: He admitted immediately that it is costing him considerably more, in fact, about four times as much, to heat his cars by electric heaters as it did by coal stoves. He says, however, that he saves two seats in the car; that the people like the system of heating, and the cars are more attractive for this reason, and that on the whole he believes in it and would not go back to the old system, nor would he fail to adopt electric heating if the decision were to be made again."

This expression of opinion has been selected, notwithstanding the unfavorable comparative cost statement, to illustrate how far we have to be governed by collateral advantages in deciding for or against any particular application of electricity for heating purposes.

More large contracts for electric car heaters have been closed the past season than ever before ,and there is every evidence that the electric car heater has become a staple commercial device. It would seem, in view of the facts, that the statements contained in Vol. I of the transactions of this society regarding electric car heaters should not stand without correction. The Metropolitan West Side Elevated Railroad of Chicago are now heating by electricity 155 cars, each 38 feet 8½ inches long; 7 feet 10 inches wide; center height, 8 feet 6⅞ inches; side height, 6 feet 7¾ inches. Glass surface is 208 square feet. There are 12 heaters to each car, using maximum of 7,000 watts. The energy used is divided in two parts of 2,600 watts each and one part of 1,800 watts. The practicability of the equipment is shown by a recent order for 25 more equipments.

II. Air Heaters.—Outside of car heating these heaters have been used to a wide extent. One of the largest installations is in the office building of the Cataract Construction Company, at Niagara Falls, where all the heat is derived from this source. In cabins of steamships and yachts, bath-rooms of houses, offices, libraries, etc., they are found useful devices. The writer pointed out in "Heating and Ventilation" for December, 1895, the relation which these heaters bear to steam heating systems.

In England and France some installations have been made on a considerable scale, and the work is, of course, simpler than the problem confronting us in this latitude, where the maximum capacity requires to be nearly twice the average. In heating the Vaudeville Theater in London, the engineers write that they had to compete against a low pressure hot water system. There was difficulty in finding a suitable place for the furnace on that system, and in using electricity this difficulty was overcome. It is found in ordinary cold weather that only two or three hours' heating are required, but with hot water systems it is impossible to limit the time in this manner, as the water takes two or three hours to heat up and the same time to cool down. The charge for current is 4d. per unit (about 6 cents per horse power hour). The lessees of the theater have expressed themselvs perfectly satisfied with the results.

In this work the fact that heat is used only intermittently produces economical results, with even very high current rates. Take the case of a bath-room; capacity of heater, one horse power; duration of use per day, 20 minutes; rate for power, 10 cents per horse power hour; cost per day 3 1-3 cents, or practically $1 per month.

III. Electric Cooking.—The results obtained in this line have been in a number of detached installations. Enough has been accomplished to show that electric cooking apparatus is practicable to use, economical in running cost, and extremely simple to operate.

Theoretically, of course, the oven is the device of highest efficiency, and it is also found in practice a device of the greatest practical value. In "Science" for September 15, 1893, will be found the most comprehensive data regarding the comparative cost of operating the electric oven and the common coal range yet published. It is shown that the cost at average rates for electricity is practically the same for the coal range and electricity, provided an auxiliary water heater is used with the electric oven. It is not always possible in practice to confine the electrically heated apparatus to types as economical as the oven; but in a plant operated for several months and in which ordinary types of cooking utensils were used, the cost was found to be 2.5 cents per person per meal. Separating the energy used in this latter case for cooking from that employed for water heating and the cost would be reduced by about one-third, or to 1.7 cents per person. Even at the 2.5 cent rate the cost (including time and attendance) compares favorably with other sources of heat for cooking.

IV. Industrial Applications.—In factory work all the elements for a multipotential heat supply are usually present and the field for electrically heated devices extensive. Three examples have been selected as illustrating this class of work.

A Equipment of a Brush Factory.—In this instance pitch is used to fasten bristles in the brushes, and is kept above 300 degrees F. in jacketed electrically heated pans. In addition, hot plates and glue pots are used, all heated by electricity. Current is derived from a dynamo driven by a gasoline engine. For a run of ten hours the cost of heating each pitch pan is about 4.5 cents, which is considerably less than was the cost of running by gas.

Commenting on this plant, the owner writes:

"When we built our factory we had confronting us the problem of obtaining high temperature for heating pitch and other applications without employing gas or other forms of flames or fire in the shop which were objectionable from the underwriters' standpoint, and which we have solved by the adoption of electricity for these purposes."

1 Abstract of paper read before the Am. Society of Heating and Ventilation.

B. Sad-irons in a Linen Factory.—This installation consists of 125 9-pound irons heated to about 750 degrees surface temperature. For this plant additional dynamos were bought, and its success is evidenced by the fact that it is shortly intended to double the equipment. Each iron uses 550 watts, or about ¾ horse power per hour as a maximum.

C. Glue Pots in Book Binderies.—Two installations of 25 pots each. These show the value of electric heating in the subdivision of heat energy. The pots are provided with water bath, and the energy supply so adjusted to compensate for heat loss without material evaporation. The energy used by each pot is from 150 to 200 watts.

These may be regarded as typical illustrations and indicate roughly the adaptability of electric heating in industrial work. Where electricity is used in place of flame or fire the ventilating problem becomes much simpler, and this is of great importance in crowded work-rooms.

It is not too much to claim that electric heating will materially influence the work of heating and ventilating engineers. Now that electric lighting installations are handled by heating and ventilating engineers, it is a short step to render the entire heating system homogeneous, looking to one source—the boiler—for all the energy needed for heating, lighting and ventilating. It is possible to economically regulate and provide storage capacity for both the high and low temperature factors; the plant becomes compact, self-contained, and simple and economical in units of moderate size. The system is elastic to the highest degree.

THE GENERATION AND DISTRIBUTION OF CURRENT BY AN EDISON STATION.[1]

THE author began by giving a brief account of the inception and early history of the Edison Electric Illuminating Company of New York, in connection with the operation of the old Pearl street station, which was started September 4, 1882, and details of which will be found in "The Electrical Engineer" of January 8, describing the work of the company. The author then continued:

Before proceeding with a description of this station, it may not be inopportune to give a few thoughts to the general problems involved in the modern station from an engineering point of view. The operations involved in the business of the supply of electric current from a central station for transformation into heat, light and power divide themselves readily into two broad divisions—generation or manufacture, and distribution or subdivision.

The generation or manufacture of current includes the cycle of operation conducted within the station itself, involves the transformation of the heat energy stored in the coal into dynamic energy, its transformation into electric energy, and its delivery to the switchboard. The operations involved in the distribution of the current are effected mainly without the station, and involve its delivery through a network of mains and secondary conductors to the local centers of consumption, where, through translating devices, the current is transferred into the form of energy desired—light, or dynamic energy.

The various processes involving the generation of electric current on a scale rendering possible its industrial utilization are, except where water power is available, the direct results of chemical action, usually the combustion of coal. The operations a central station conducts are the economical burning of coal, the imparting of its heat energy to the water in the boiler converting it into steam, the dynamic force of which impels the piston of the engine, resulting in the movement of conductors through the lines of force of an electro-magnet, thereby generating electric current.

Of the several steps of this cycle, the important ones are mechanical. The economical burning of coal on a grate, although a chemical process, has been reduced by accepted types of boiler furnaces to a mechanical operation requiring some common sense and a stout arm, but no chemical formula. The electric generators involved are relatively simple, and the perfection to which electrical construction has already attained has confined further possibilities in this direction to improvements affecting the investment rather than operating accounts. I speak of this somewhat elementary proposition for the purpose of calling to mind and emphasizing the fact that in the modern central station the problems within the station—problems of generation or manufacture—are in mechanical rather than electrical engineering. The best types of multi-expansion condensing engines rarely transform more than 15 per cent. or 16 per cent. of the heat energy of the coal into dynamic energy, and, in the common forms of non-condensing engines, not more than 6 per cent. of the coal energy is available at the flywheel of the engine. Under the conditions found in most electric light stations, these efficiencies cannot be approached. Taking into account the variable loads on engines and boilers, condensation in steam pipes to the power required for the auxiliaries, with the other losses, the total efficiency of the transformation into electric current seldom, if ever, exceeds 8 per cent., and is usually not greater than 3 per cent.

The electrical efficiency of the best types of dynamos of the size used in the larger stations is seldom less than 90 per cent., and, in the larger sizes, is as high as 96 per cent. These efficiencies diminish but little under the partial loads ordinarily carried in a well-designed station having generating units of several sizes to maintain a high ratio of capacity to output. With the generators at this (Duane street) station it is possible to obtain a ratio of output to dynamo capacity in operation of 92 per cent. between the hours of 9 a. m. and 6 p. m.; during the twenty-four hours this ratio is reduced to an average of 85 per cent, as the smallest unit available has a capacity considerably in excess of the requirements during the minimum hours. Exhibit: Blueprint diagram of capacity and load curves at Duane street station.

It is safe to say that of the energy delivered to the engine shaft, from 75 per cent. to 85 per cent. in the smaller stations, and from 85 per cent. to 90 per cent. in the larger, is delivered as electrical energy to the switchboard, including losses due to the inefficiency of the dynamos, in the leads to the switchboard, in the contacts, etc. It is evident, therefore, that the losses due to the inefficiency of the electrical apparatus in the station are small as compared with those due to the inefficiency of the apparatus engaged in the conversion of heat energy into dynamic energy, and in the auxiliary apparatus the great problem in the mechanical operation of a station is to reduce these losses to a minimum, approaching as nearly as possible the conditions of maximum economy—the coal consumption, per unit generated, approaching what its value would be if the whole station were operated at the load of maximum efficiency for the twenty-four hours.

The problems which are more specifically electrical in their nature are those connected with the delivery of the current from the switchboard into the system of mains and feeders which distribute the current to the consumer's premises and its transformation there in the form of energy desired. I will not undertake to point out here the numerous methods available for effecting this end, but will confine myself strictly to the system under consideration.

The loss of energy in the conduction of current from the switchboard to the point of consumption depends upon the factors, current, pressure, sectional area of conductors and their length. For each particular case there exists a fairly definite relation, from which, given the cost of producing the current, the average use of current, or the load factor, the distance to the point of consumption and the cost of the conductor per unit area, the most economical section can be determined. It would, of course, be out of the question to make this calculation for each consumer, or group of consumers, but it must be taken into account when it is a question of supplying current at considerable distances from the station. Erroneous ideas are held as to what the actual losses are in a network of feeders, mains and services distributing current from an Edison station. It may be interesting to note that the drop of voltage, due to resistance of conductors between the switchboard and the consumers' services, on the Edison system in New York amounted to an average of 7 per cent. during 1895. To this should be added an average drop of 2 per cent. to 2½ per cent. on the consumers' wiring between the services and the lamps. This drop has been reduced considerably, as well as the investment cost for conductors, by the use of two or three "bus" pressures in the modern station, grouping the distant or heavily loaded feeders on the "bus" carrying the high voltage, and the short or lightly loaded feeders on the low "bus." The same result is obtained by the use of a "booster" inserted in series with the feeder, which adds to the "bus" pressure the voltage necessary to overcome the drop.

Notwithstanding the much-talked-of leveling of the station load curve due to the installation of motors, it will be found that as a station increases in capacity the ratio of maximum load at any time to the total connected installation will continue to fall. There is a limit, of course, beyond which this decrease is not likely to go, depending largely on the further uses to which electricity will be applied.

In an industrial district, where the motor load is heavy nearly all day, the lighting load is comparatively light, except during the winter, when darkness sets in early, and the motor and lighting loads overlap. In a district of this kind, moreover, there is but small demand for light at night. In a residential or shopping district, on the contrary, the motor load is of less importance, and the lighting load becomes great immediately upon the approach of darkness, reaching a maxi-

[1] Abstract of a paper read before the N. Y. Electrical Society, Feb. 26, 1895.

mum in the evening and extending some into the night. (Exhibit.)

These characteristics are clearly shown by the two curves of the diagram before you, one representing the load of the First District, extending from the Battery to Fourth street, the other, the load of the Second District, extending from Fourth street to Eightieth street, on the East Side. In the First District motors represent nearly 42 per cent. of the total installation, and the output to motors during last year was nearly 45 per cent. of the total output of the district. The ratio of maximum load at any time to connected installations varied from 21 per cent. in summer to 38 per cent. in winter, the load factor—the ratio of average load to maximum load—averaging about 26 per cent. during the entire year. In the Second District the motors represent only 17 per cent. of the total installation, and the current delivered to them during the year represents only 16 per cent. of the total output of the district. Yet the percentage of maximum load to connected installation varies from 16½ per cent. in summer to 38 per cent. in winter, while the load factor exceeds an average of 30 per cent. --more than 4 per cent. higher than the average of the First District.

It is interesting to note that the daily average use of each incandescent lamp installed is almost identical with the daily average use per rated horse power of motors installed. This fact, if taken alone, would be misleading; it should be remembered that an incandescent lamp is used at its full candle power, whereas the current consumed by the motors will average less than one-fourth or one-third their rated capacity.

Although motor service is, on the whole, advantageous to a station, owing to the long average use in proportion to the time of maximum current demand, and can, therefore, be sold at a considerably lessened rate than in the case of arc or incandescent lighting, it is not an ideal service. This is due to the fact that the motor load overlaps the period of maximum demand for lighting, and, therefore, becomes part of the maximum load on the station, for which generating and distributing capacity must be provided. The ideal service for leveling the load curve, which all station managers are striving to do, is one which ceases before the time of maximum lighting, and which would not, therefore, call for additional and special investment. It is hoped that some such application may appear in the many uses which are being found from time to time for the electric current. (Additional Exhibits: Comparative output of London, Berlin and New York Edison stations. Characteristic output curve of each month of the year. Curve of monthly variation of maximum, average and minimum loads. Loads on special days: Christmas, Fourth of July, heaviest load during year, etc.)

Owing to Mr. Lieb's illness, the part of the paper referring specifically to the Duane street station was not finished. Mr. R. R. Bowker, first vice president of the company, addressed the meeting, pointing out the characteristic features of the station construction and equipment.

PERSONAL.

A PRESENTATION TO MR. W. J. FRASER.

On February 25 the staff of the Direct United States Cable Company at Rye Beach and Boston presented Superintendent W. J. Fraser, of Rye Beach, with a solid silver, triple-handed loving cup, as a token of their high esteem and in commemoration of his service at that place for twenty years, from 1876 to 1896. The cup bore a fitting inscription. It was accompanied by a handsome cake, with similar inscriptions, and entwined with strands of cable in the form of true lovers' knots.

After this Mr. J. C. Shaw, of the Boston Cable staff, presented Mrs. Fraser with a splendid bouquet in the name of the officers of the well-known cable steamer, "Minia" (Anglo-American Company), many of whose officers were present. The remainder of the evening was spent in a delightful manner at Mr. Fraser's residence, with music, games, dancing and refreshments, the party being large and representative.

AN ELECTRICAL ENGINEER ON HIS TRAVELS.

Mr. T. Ahearn, wife, two children and maid, of Ottawa, Canada, are staying at the Bristol, having arrived per steamer "Oceana" from Sydney on the 13th instant, since which time Mr. Ahearn and family have visited Nuwara Eliya and Kandy, and they speak flatteringly of Ceylon. Mr. Ahearn is a prominent Canadian electrical engineer, and is closely identified with a number of the largest electrical enterprises in the Dominion, his firm, Messrs. Ahearn and Soper, having pioneered the electric tram in Canada, and having installed extensive plants in the principal cities of that country, where electric traction has entirely superseded the horse. The trams are successfully operated on wheels throughout the winter, when vast quantities of snow fall, as huge rotary snowsweepers propelled by electricity keep the tracks clear. Mr. Ahearn will continue his trip around the world, sailing for Calcutta in the "Nubia" on Thursday next, and, after crossing India by rail, will sail from Bombay for Europe.—"Times of Ceylon."

LETTERS TO THE EDITOR.

THE COMING CONFERENCE ON UNDERWRITERS' RULES.

On behalf of the Committee on Standard Rules for Electrical Construction and Operation of the National Electric Light Association, I write to state that after mature deliberation it has been decided to extend an invitation to the Underwriters' National Electric Association to send a delegate to the joint conference to be held on March 18 and 19. This association has been added to the list of eleven organizations already co-operating which was published in the recent issue of your journal. Our committee was led to this action which has been under consideration for some time past by reason of the fact that they felt that while the insurance interests of the country would be ably taken care of by the representatives of the National Board of Fire Underwriters, and although they realized that the Underwriters' National Electric Association, acting merely in an advisory capacity, being composed of the electrical inspectors from all parts of the United States and having no authority in itself as an association, so closely were they identified with the preparation, indorsement, and enforcement of rules for electrical construction and operation and so alive to the practical questions which would come before the joint conference, that the committee felt it advisable to extend an invitation to their organization to send an official delegate on the same par with the eleven other interests already invited.

I append herewith a list which has been prepared of complimentary delegates to be invited to the joint conference in an advisory capacity, but solely as individuals and not as representing any association or manufacturing interests: Wm. McDevitt, Inspector Board of Fire Underwriters, Philadelphia, Pa.; A. E. Kennelly, Consulting Engineer and Expert, New York; W. J. Jenks, Electrical Engineer and Expert, New York; A. H. Henderson, Chief Inspector Fire Department, New York; Morris W. Mead, Superintendent Bureau of Electricity, Pittsburg; Professor Wm. A. Anthony, Consulting Engineer; E. H. Johnson, New York; S. E. Barton, New York; E. V. French, Inspector Factory Mutual Fire Insurance Company, Boston.

The committee has in preparation a transcript of the various codes most extensively in use, and this, in a convenient and compact form, will be in the hands of each delegate prior to the meeting, at which meeting a large amount of additional matter bearing upon American and European practice will be available, and it is the intention that in the consideration of the various rules presented at the joint conference, the decision as to what shall be adopted for the national code will be governed solely by the law of the "survival of the fittest."

W. J. HAMMER,
Chairman Committee National Electric Light Association.
New York City, March 6.

CONTAINS THE NEEDED INFORMATION.

"The Electrical Engineer" possesses one feature which makes it invaluable to the up-to-date electrical fraternity. It always contains just exactly what one wants to know about. Your descriptions of new developments, important electrical industries, and, in fact, each entire issue is always timely, valuable and highly interesting.

JOSEPH SACHS.
New York City.

A REFRESHING CHANGE.

I noted with pleasure the article so fully describing and illustrating the works of the New York Edison Company, in the issue of "The Electrical Engineer" for January 8th. You are to be commended for this admirable article. I was especially pleased to find the full description of stations and apparatus supplemented by details of operation. This even eclipses a former account of the Chicago Edison station. I trust you may favor your readers with more matter of this character. It is a refreshing change from the usual descriptions of electrical plants. Wishing you the continued success you deserve,

W. M. STINE,
Department of Electricity, Armour Institute,

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED MARCH 3, 1896.

Alarms and Signals:—

DISTRICT ALARM SYSTEM. M. E. Barrett, Chicago, Ill., 555,491. Filed April 16, 1895.

The transmitting instruments are arranged in circuit in such a manner that the opening of the circuit need not block the transmission of signals.

ELECTRICAL RAILWAY SIGNAL. W. Fiedler, Charlottenburg, Germany, 555,601. Filed Aug. 25, 1894.

Has for its object to dispense with traction wires for operating semaphore signals and to provide an operating apparatus which may be attached to existing signals.

SIGNALING CIRCUIT. J. J. O'Connell, Chicago, Ill., 555,707. Filed Dec. 23, 1895.

Comprises a system in which the signal sending appliances at one station when actuated remain in their working position, effectuating the continuous giving of the signal at the other station until the attendant at the other station takes proper action in response thereto.

Conductors, Conduits and Insulators:—

METHOD OF AND APPARATUS FOR PREPARING AND TREATING ELECTRICAL CONDUCTORS. C. E. Carpenter, Bridgeport, Conn., 555,895. Filed Nov. 16, 1893.

Consists in first shaping the conductor, then placing the same upon a supporting body, then heating the conductor until it becomes limp or inelastic, and then allowing it to cool.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE AND ELECTRIC MOTOR. G. A. Welles, Jr., New York, 555,544. Filed April 12, 1895.

A single coil multipolar magnet, provided with arms radiating from core at either side of its coil, and terminating with U-shaped pole pieces alternating in sign.

MONOCYCLIC GENERATOR. E. Thomson, Swampscott, Mass., 555,590. Filed March 29, 1895.

A main armature generating single phase alternating current, an auxiliary armature, comprising a winding upon a separate core from the main armature, but mechanically connected with the main armature and generating an electro-motive force of displaced phase, and a connection between the teaser-armature and the main armature.

ARMATURE FOR DYNAMOS AND MOTORS. G. A. Welles, Jr., New York, 555,628. Filed April 12, 1895.

Built up in segmental sections and provided with coils so placed thereon that spaces are left on the outer periphery thereof, in combination with a circular retaining ring.

CORE AND COIL FOR DYNAMO ELECTRIC MACHINES. A. L. Cushman, Concord, N. H., 555,850. Filed Aug. 29, 1894.

An inductive core provided with grooves or recesses of equal width from top to bottom, coils or windings composed of insulated wire all of equal length, and suitable end caps for inclosing the coils or windings, each having an internally, projecting flange or ring adapted to support said coils.

ARMATURE FOR INDUCTION MOTORS. A. L. Cushman, Concord, N. H., 555,851. Filed Aug. 13, 1894.

An armature having the short-circuit multiple windings and short-circuit coils closed in series, arranged in such numbers and relation one to another as to cause unsymmetrical polarities.

ARMATURE FOR INDUCTION MOTORS. A. L. Cushman, Concord, N. H., 555,899. Filed June 24, 1895.

An armature winding composed of coils, each of which forms a short circuit rectangle, the coils being of such length as will cause each set of successive coils to reach by or overlap each other.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. R. Schefbauer, Hoboken, N. J., 555,621. Filed Aug. 8, 1895.

Mechanism relating to an inclined carbon arc lamp.

ELECTRIC ARC LAMP. E. Lavens, New York, 555,706. Filed May 23, 1895.

Its object is to simplify the construction of arc lamps by decreasing the number of operative parts.

ELECTRIC ARC LAMP. T. E. Adams, Cleveland, O., 555,841. Filed June 6, 1895.

Relates to the contact or gripping surfaces of friction clutches for electric arc lamps.

ELECTRIC ARC LAMP. T. E. Adams, Cleveland, O., 555,891. Filed Oct. 10, 1895.

The combination with a separating magnet and the carbons, of a pivoted lever connected with the carbons, and a flat spring secured at one end to the pivoted end of the lever and connected at the other end to the armature of the magnet.

Measurement:—

ELECTRIC METER. G. A. J. Telge, Oldenburg, Germany, 555,589. Filed Feb. 21, 1895.

The pendulum of a clock movement is caused, by means of a pivoted or rocking beam under the influence of a solenoid core, to undergo variations in length, position or tension, so that the difference between the times indicated by the clocks will give a direct measure of the quantity of electricity that has passed through the solenoid.

ELECTRICAL MEASURING INSTRUMENT. A. H. Hoyt, Penacook, N. H., 555,702. Filed June 10, 1895.

The combination with a spring supported armature, of a pointer adapted to travel over a suitably calibrated scale, and a multiplying connection between said armature and pointer.

Miscellaneous:—

METHOD OF CONVERTING POTENTIAL ENERGY OF CARBON INTO ELECTRICAL ENERGY. W. W. Jacques, Newton, Mass., 555,511. Filed June 5, 1895.

See page 261.

ELECTROMAGNET FOR SEPARATING METALS. H. H. Whitacre and A. C. Wolfe, Wellsville, O., 555,546. Filed March 1, 1895.

Combination of a series of magnets radially disposed about and parallel with a central axis.

ENGRAVING MACHINE. B. S. Molyneux, Minneapolis, Minn., 555,581. Filed May 1, 1894.

The combination with a graver or drill, of an electric motor, with the motor armature and the drill on a common shaft which is free for sliding movement in fixed bearings.

METHOD OF AND APPARATUS FOR MAGNETIC SEPARATION. J. P. Wetherill, South Bethlehem, Pa., 555,792. Filed Feb. 10, 1896.

An electromagnet having a pole piece tapering toward its free end and having a core substantially equal in breadth to the pole piece, and a conveyor passing around the pole piece for introducing the ore into the magnetic field and withdrawing the attracted material from said field.

SEPARATION OF FRANKLINITE ORE AND METALLURGY THEREOF. J. P. Wetherill, South Bethlehem, Pa., 555,793. Filed Feb. 10, 1896.

Similar to above.

MAGNETIC SEPARATOR. J. P. Wetherill, South Bethlehem, Pa., 555,794. Filed Feb. 10, 1896.

Similar to above.

ELECTRIC COAL CUTTER. I. E. Storey, Boulder, Colo., 555,832. Filed Dec. 20, 1890.

The combination with a motor and its shaft, of a counter shaft passing between the field magnet coils, bevel pinions carried by the counter shaft, a bevel gear with which said pinions are adapted to engage a cutting chain driven by said gear and a feeding mechanism driven by said counter shaft.

TIMING APPARATUS. G. F. Brackett, Jersey City, N. J., 555,847. Filed March 14, 1895.

The combination with a time movement, and time movement stop mechanism controlled by the stop mechanism and means for actuating the stop mechanism.

Railways and Appliances:—

CLOSED CONDUIT ELECTRIC RAILWAY. C. Anderson, Leeds, England, 555,487. Filed March 1, 1894.

The conductor is laid in a closed conduit; the rails are used to complete the circuit.

CLOSED CONDUIT ELECTRIC RAILWAY. C. Anderson, Leeds, England, 555,488. Filed Feb. 13, 1895.

Employs vertically movable contact pegs and means to operate same by approaching car.

ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 555,500. Filed June 21, 1894.

Has for its object the substantial elimination of the tracks and earth as the return conductor, and using the tracks essentially as a bridging media between the positive and return conductors of the electric railway.

MOTOR HANGER FOR ELECTRICALLY PROPELLED CARS. E. Peckham, New York, 555,529. Filed June 11, 1895.

The combination with an electric motor pivotally connected at one end to the axle of the truck, of longitudinal motor hangers, pivotally connected between their ends to the sides of the motor and supported at each end from the frame of the truck.

TROLLEY PROTECTOR FOR FIREMEN. J. P. Barrett, Chicago, Ill., 555,534. Filed Dec. 13, 1895.

A support which makes contact between the trolley wire and track, short circuits them and blows the fuse at the station.

TROLLEY POLE AND CONNECTION. C. H. Finson, Pittsfield, Me., 555,571. Filed July 20, 1895.

Has for its object to prevent the trolley, when it has accidentally left the wire, from flying above said wire.

SAFETY APPLIANCE FOR ELECTRIC BRAKES. W. B. Potter, Schenectady, N. Y., 555,585. Filed April 22, 1895.

Comprises a braking switch, a circuit, including brake magnets and a source of electro-motive force, a solenoid having its core attached to and controlling the braking switch, and means for actuating the solenoid by excess of current in the circuit.

TROLLEY HEAD. W. H. Carr, Bath, Me., 555,764. Filed Oct. 15, 1895.

The frame supporting the wheel is pivoted at nearly a right angle to the arm, insuring ease in turning curves.

ELECTRIC PROPULSION SYSTEM FOR CARS. G. H. Melotte, Marsh, Pa., 555,783. Filed Aug. 15, 1895.

A trolley wire so strung as to cross the path of the trolley at definite intervals in alternate directions and a trolley of such a length as to always be in contact with one or more of such crossings.

ELECTRIC RAILWAY SYSTEM. A. J. Beltzel, Boiling Springs, Pa., 555,800. Filed April 15, 1895.

A series of switches suitably connected, contact points extending therefrom, levers for making and breaking current, and a rod connected with the lever and protruding into the grooves of the rails and operated by suitable throws on the car.

BOND OR CONNECTOR FOR ELECTRIC RAILWAYS OR OTHER ELECTRIC CONDUCTORS. A. Bournonville and J. J. Zimmele, Philadelphia, Pa., 555,846. Filed Sept. 20, 1895.

A bar having a body half round or segmental in cross-section and an end reversed on itself forming a divided head which is adapted to be spread apart.

ELECTRIC RAILWAY BRAKE. J. C. Henry, Westfield, N. J., 555,862. Filed July 3, 1895.

Employs a combined dynamo and magnetic clutch on one axle of each car, and means for operating a drum normally loose on the axle, to wind up the brake chain.

Regulation:—

CONTROLLING MECHANISM FOR ELECTRIC MOTORS. L. T. Gibbs, Milwaukee, Wis., 555,503. Filed Jan. 2, 1896.

A lever adapted to gradually cut out of the armature circuit a series of resistances in starting the motor, and an automatic safety switch.

Telegraphs:—

FAC-SIMILE TELEGRAPHY. A. W. Storm, Ramsey, N. J., 555,626. Filed Sept. 11, 1895.

A message having a design partly of non-conducting and partly of conducting substance thereon, in combination with a telegraphic transmitter, having a circuit closer with adjacent contact points.

Telephones:—

TELEPHONE CALL REGISTER. H. Hempel, Berlin, Germany, 555,645. Filed April 9, 1895.

Means of control or indication of use of the telephone by subscribers is obtained so far as the subscriber is concerned, while the use of it on the part of the summoned subscriber is not controlled.

PARTY TELEPHONE LINE APPARATUS. A. S. Hibbard, Chicago, Ill., 555,725. Filed Sept. 16, 1895.

Means whereby a number of telephone sets may be connected with a party line and selective signals sent over the line to ring with bell at any one of the sub-stations without affecting the remaining bells. Uses polarized signal bells.

LEGAL NOTES.

INJUNCTIONS GRANTED AGAINST MANUFACTRERS OF TROLLEY STANDS ON THE VAN DEPOELE UNDER RUNNING TROLLEY PATENT.—THE GENERAL ELECTRIC CO. VS. BILLINGS & SPENCER AND KELSEY ELECTRIC RAILWAY SPECIALTY CO.

An interesting and important decision has just been rendered by Judge Townsend, of the United States Circuit Court for the District of Connecticut, upon the Van Depoele patent No. 495,443, for the under-running electric railway trolley system.

A few months ago Judge Townsend rendered a decision sustaining the validity of the patent upon final hearing in a suit against the Winchester Avenue Railroad Company, of New Haven. Shortly thereafter further infringement suits were brought in Connecticut against the Billings & Spencer Company, of Hartford, and the Kelsey Electric Railway Specialty Company, of New Haven. Judge Townsend has just decided these suits in favor of the Van Depoele patent, and granted motions for preliminary injunctions after full argument on both sides.

The decision is especially important because the court holds that the supply of essential or characteristic parts of the trolley system is a contributory infringement, and will be enjoined by the courts, even though the defendants may not supply or use the patented combination or system in its entirety. The court further held that an unlicensed maker of trolley bases could not be permitted to supply such bases even to railroads which had been originally fully equipped by the General Electric Company.

From the court's opinion, it appears that the defendants in this instance made and sold trolley stands or bases; they urged that such bases were not covered in detail by the patent as a separate article of manufacture and further contended that they at least might be lawfully sold to or used by purchasers to repair or replace parts of original equipments furnished by the Thomson-Houston and General Electric Companies, under the authority of the Van Depoele patent. But the court held that neither of these things could be lawfully done. First, because the supply of parts of the patentee's system is in reality intentionally aiding other parties in the unlawful making, selling or using of the patented system as a whole. Second, because the replacement of a lawful by an unlawful trolley base or stand is not a legitimate repair, but a reconstruction of the combination patented. In other words, infringement and injunction cannot be avoided by making up a complete system of parts gathered together from various sources, but on the contrary, all parties who contribute towards the infringement of the entire combination by supplying necessary and durable parts thereof, are themselves infringers, and subject to injunction.

A large number of prior decisions were referred to by the court, where rulings of a similar nature have been made, which establish the general doctrine that any supply of parts amounting to the intentional promotion of the act of infringement by others will be restrained by injunction, and that the full scope of the Van Depoele patent cannot be avoided in this way, even if the parts so supplied or used are not claimed by themselves alone as specific and separate features of the patented invention.

THE BERGMANN SOCKET PATENT NOT CONTROLLING—EDISON ELECTRIC LIGHT COMPANY vs. ELECTRIC ENGINEERING AND SUPPLY COMPANY OF SYRACUSE.—OPINION OF JUDGE COXE.

The patent, No. 311,100, on which this action is founded, was granted to Sigmund Bergmann January 20, 1885, for improvements in sockets for incandescent electric lamps. The improvements relate to sockets designed to receive lamps whose terminals are a screw-fastened ring and a plate on the base of the lamp. The object was to provide a compact socket, having few parts, a small amount of insulating material and a simple circuit controller. * * *

The claims in dispute were:

1. In a socket for an electric lamp, the combination of two circuit terminals, one a sleeve adapted to make contact with the band or ring terminal, the other a spring movable into and out of contact with the bottom terminal of the lamp, substantially as set forth.

3. In a socket for an electric lamp, the combination, with a disk of insulating material, of a contact-sleeve for making contact with the band or ring terminal of the lamp, a contact-piece for making contact with the bottom terminal of the lamp, and two terminals for the circuit-wires leading to the socket, all said socket contacts and terminals being carried by the said insulating-disk, substantially as set forth.

4. In a socket for an electric lamp having two terminals for making connection with corresponding lamp materials, the combination of a metal-supporting portion and a disk of insulating material carried thereby, and carrying all the terminals and contacts of the socket, substantially as set forth.

9. The combination, with a contact-spring, substantially of the form described, of a separate turning-key bearing against said spring, whereby it may be forced upward to make contact, substantially as set forth.

13. In a socket for electric lamps, the insulating body which supports the terminals or connections, formed of non-combustible material, substantially as set forth.

It is unnecessary to discuss at length the many questions presented by the elaborate record and briefs, for the reason that when subjected to analysis it must be found that Bergmann's claim to invention rests upon two narrow foundations; first, the character of the insulation, and, second, the form of the circuit controller or key. Unless invention can be found in these two features it can be found nowhere.

The use of combustible insulating material in this art was very old. Soapstone, glass and plaster of paris had been used and porcelain had been suggested by Gordon in 1880. * * *

An examination of this record must convince the impartial reader that the use of non-combustible insulating material in this analogous situation was not new with Bergmann, and that its advantages were recognized by a number of electricians long prior to the date of his patent. If the disk claims are construed broadly as covering all kinds of non-combustible insulating materials, they are clearly because non-combustible material had been used in similar combinations, and if these claims are limited to lava, the defendant does not infringe, for the reason that it uses porcelain and not lava. * *

Circuit breakers in the sockets of incandescent lamps were old at the date of the patent in suit. One of these was before the court in Schuyler Electrical Company versus this defendant, 62 Fed. Rep., 588; 66 Fed. Rep., 313. It was there held that as early as 1881 a claim for such a device must be limited to the precise mechanism shown and described. Since that date, and prior to the date of Bergmann's application, key circuit controllers operating in a great variety of ways were devised by a number of electricians, including Bergmann himself. It is not, of course, pretended that a circuit controller located in a lamp socket was new with Bergmann. All that is claimed for his key is that it is simpler and better than those which preceded it. The specification says: "The circuit controller making and breaking circuit upon the lamp tips employs fewer parts and is simpler in construction than any heretofore used." In short, as to both branches of the controversy, it is perfectly obvious that Bergmann is in no sense a pioneer. Unquestionably he produced a simple, compact, durable and efficient socket, but the art did not begin with him, and it ought not to be held to end with him. He has originated no new principle of operation; he has produced no new result. He improved upon existing structures. Other inventors should be permitted to do the same. With the exception of claim 13, which, it would seem, is too broad to be upheld upon any rational theory, the claims in question may be sustained if confined to the precise structures described and shown. They cannot, however, be held to suppress improvements which differ from Bergmann as essentially as he differs from the prior art. * * *

The court then points out the differences between the defendant's socket, made under the Hinds, 1891, patent, and that of Bergmann, and continues:

"If the broad construction contended for by the complainant were permissible the defendant would, unquestionably, infringe, but with the limited construction made necessary by the prior art and by the language of the patent it is equally manifest that the defendant does not infringe. Upon the whole case the court is satisfied that Bergmann was simply an improver upon the prior art in matters of detail only, and that he must be confined strictly to what he had described and shown." * * *

The bill is dismissed.

C. S. Mitchell and R. N. Dyer, for the complainant; Alfred Wilkinson, for the defendant.

APPROVING THE NEW YORK UNDERGROUND.

The Commissioners, F. R. Coudert, G. Sherman, and W. H. Gelshenen, who were appointed by the New York Supreme Court to determine by public hearings the advisability of the underground road proposed by the Rapid Transit Commission, have filed a report approving the plan.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, of Scranton, Pa., are now issuing a handsome monthly paper, called "Home Study," for students in the industrial sciences and others who need fuller knowledge of arithmetic, geometry, trigonometry, physics and drawing, in order to enable them to derive the best results from their study and reading. The paper is well put together and full of helpful, systematic information.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Institute, February 26, the report of the Committee on Incorporation was read, and a resolution empowering the council to proceed with the work of incorporation was unanimously adopted.

The discussion of Mr. Sprague's paper on "Electric Elevators" was then taken up, in accordance with a vote of the meeting, January 22, when lack of time prevented some members from participating. The discussion was reopened by Dr. Hutchinson, who presented the results of actual tests made. He was followed by Messrs. Geo. Hill, R. P. Bolton, H. Ward Leonard and others.

At the meeting of the council, in the afternoon, the following associate members were elected: Daniel Adamson, manager John Adamson & Co., Hyde, Cheshire, England; Isaac F. Badeau, assistant to the engineer, Metropolitan Telephone and Telegraph Company, residence 213 West One Hundred and Twenty-first street, New York City; Samuel D. Collett, engineer construction department Metropolitan Telephone and Telegraph Company, 18 Cortlandt street, New York City, residence 15 Cranberry street, Brooklyn, N. Y.; Edward P. Decker, electrical engineer, Metropolitan Telephone and Telegraph Company, 18 Cortlandt street, New York City, residence Van Pelt Manor, S. I.; Samuel L. Foster, electrical engineer, Market Street Railway Company, 19 Hobart Building, residence 839 Twenty-fourth street, San Francisco, Cal.; Eugene E. Griffes, senior partner, firm of Griffes & Sumner, 307 South Main street, Los Angeles, Cal.; Ralph L. Montague, chief of electrical department, the Gold Dredging Company, Bannack, Mont.; Edwin S. Reid, superintendent of construction, Standard Underground Cable Company, 18 Times Building, New York City, residence 116 West Eleventh street; E. C. Sharpe, consulting electrical engineer, 20 Potomac Block, Los Angeles, Cal.; Edward Sullivan, United Electric Light and Power Company, 108 Fulton street, New York City, residence 337 West Eighteenth street.

The following associate members were transferred to full membership upon recommendation of the Board of Examiners: Geo. D. Shepardson, professor of electrical engineering, University of Minnesota, Minneapolis, Minn; Henry A. Sinclair, electrical engineer, the Tucker Electric Company, New York City; Paul N. Nunn, consulting engineer, San Miguel Consolidated Gold Mining Company, Telluride, Colo.; Geo. H. Winslow, electrical engineer, 700 Lewis Block, Pittsburg, Pa.; Wm. D. Gharky, superintendent underground cable construction and maintenance, Philadelphia Traction Company, Philadelphia, Pa.; Walter C. Fish, manager Lynn Works, General Electric Company, Lynn, Mass.

MEETING OF THE ELECTRICAL TRADES ASSOCIATION.

With the object of forming in New York an organization like that in Philadelphia, for the better protection of trade and credit, Messrs. Bournonville, of A. F. Moore; Wilkins, of the Partrick & Carter Company, and Trump, of the Novelty Electric Company, met a number of representatives of the electrical industries at the Astor House on March 4. The following local concerns were present, as thus represented:

New York Insulated Wire Company, R. E. Gallaher; American Electrical Works, Providence, R. I., E. F. Phillips and P. C. Ackerman; "Electrical Review," New York, C. W. Price; Okonite Company, New York, G. T. Manson; the E. S. Greeley & Co., New York, T. J. Smith; Safety Insulated Wire and Cable Company, New York, A. P. Eckert; Manhattan Electrical Supply Company, New York, J. J. Gorman; Union Porcelain Works, Brooklyn, C. H. L. Smith; "The Electrical Engineer," T. C. Martin and W. F. Hanks; J. J. Jones & Son, New York, E. A. Lowe; W. R. Ostrander & Co., New York, J. B. Peck; Interior Conduit and Insulation Company, New York, C. P. Geddes; Western Electric Company, New York, E. R. Gilmour; "Electrical World," New York, W. J. Johnston; J. A. Roebling Sons Company, J. P. Marshall; "Engineering Magazine," Chicago, Ill., F. DeLand; Bushwick Glass and Carbon Company, Brooklyn, M. B. Downes.

Mr. W. J. Johnston was made chairman, and Mr. A. P. Eckert secretary. The chair appointed the following committee to look into the advisability of forming the New York Electrical Trade Association: Messrs. Gallaher, Price, Geddes, Gilmour and Smith.

Letters were received from Messrs. Benedict & Burnham, represented by W. A. Hungerford; the "Western Electrician," represented by W. F. Osborn; Ansonia Brass and Copper Company, represented by A. A. Cowles.

The India-Rubber and Gutta-Percha Insulating Company have signified their intention of joining the association. The association will call a meeting for this week, the exact day to be named later by Mr. R. E. Gallaher, when definite action is looked for.

HISTORICAL AND LOAN EXHIBIT AT THE ELECTRICAL EXPOSITION.

In connection with the electrical exposition, to be held in this city next May, arrangements have been made for a very interesting historical and loan exhibit, to which it is intended to devote considerable space on the main floor. A committee, composed of T. C. Martin, Dr. Park Benjamin and E. L. Morse, has been asked to take the superintendence of this exhibit, and, having consented to do so, is already at work. Dr. Benjamin has one of the very finest libraries in the world of early books on electricity, and these will be shown in cases, arranged chronologically with explanatory notes, portraits, autographs, etc. Mr. Morse, as the son of Professor S. F. B. Morse, is the possessor of an invaluable collection of telegraphic relics, curios, documents, etc., including his father's notebooks and sketches, all of which will be shown. Mr. Martin, besides owning many objects of interest connected with the early days of electricity, has secured from Mr. Tesla, Professor Elihu Thomson, Mr. Edison, Mr. Edward Weston, Mr. Stieringer and others no less well known the loan of early and interesting apparatus, constituting a personal exhibit from each inventor of the most interesting and instructive nature.

NEW YORK ELECTRICAL SOCIETY.

Mr. George H. Guy, the Secretary of the above Society, has just issued a neat 8-page brochure, detailing its objects and giving a list of some of the more important papers that have been read before it during the period since 1887. It is a remarkable record of good work, and the society was never more active and useful than to-day. It is the oldest body of the kind in America, having been founded in 1881. We earnestly recommend young men in this vicinity, interested in electricity, to join the society, as a means of instruction and of intellectual and social enjoyment.

MR. EDISON AT THE ELECTRICAL EXPOSITION.

The public will have an opportunity to witness the new method of photographing through solids at the electrical exposition, to be held in New York City in May, in connection with the nineteenth convention of the National Electric Light Association.

Mr. Edison has succeeded in making cathodographs through eight inches of yellow pine, and anticipates no trouble whatever in making these instantaneous shadow pictures. He has generously offered to send to the exposition his most powerful and improved apparatus for making shadowgraphs, and his own corps of laboratory assistants to operate the same. This will be freely open to public examination and use.

Mr. Edison will also send to the exposition his large collection of experimental apparatus and designs pertaining to his early work on his many inventions, much of which has never yet been shown to the public.

TEXAS STREET RAILWAY ASSOCIATION.

The Texas Street Railway Association will hold its second annual convention at Galveston on March 18 next. The officers are W. H. Sinclair, President, Galveston, Texas, and C. L. Wakefield, Secretary, Dallas, Texas. These, with W. H. Weiss, of San Antonio; George B. Hendricks, of Fort Worth, and C. A. McKinney, of Houston, represent the directory. Supply men will be welcome, and space will be provided for them for exhibits, if they desire it. Applications should be made to J. K. Urie, care Galveston City Railway Company, Galveston, Texas.

A FRENCH MEMORIAL TO FRANKLIN.

A special cable dispatch from Paris of March 8 says: Several hundred persons to-day attended the unveiling of a memorial tablet that has been erected on the site of the villa at Passy occupied by Benjamin Franklin from 1777 to 1785. It was at this villa that Franklin erected his first lightning conductor in France. The dramatist, M. Manuel, President of the Passy Historical Society, presented the tablet. M. Faye, a member of the French Academy, spoke of Franklin's scientific researches.

J. B. Eustis, the American Ambassador, acknowledged the gift of the tablet. M. Roujon, Director of the Society of Fine Arts; Moncure Conway, Henry Bacon, the artist; Meredith Read, and many ladies were present at the ceremony.

PASSENGER TRANSFER STATION AT WASHINGTON, D. C.

Consolidation is the order of the day. The public are beginning to understand that monopoly in street railway traffic in small cities is not the green-eyed monster it has been painted. A passenger who can go from one part of the city to another, transferring sometimes twice and three times in the trip for one fare, does not look at the monopoly of the railroad company as he formerly did when it cost him a new fare every time he changed cars. An important problem, however, for the management to consider is the comfort of passengers at transfer points.

We illustrate on this page a transfer station lately designed and built by the Berlin Iron Bridge Company, of East Berlin, Conn., for the Washington and Georgetown Railway Company at Washington, D. C. The building is located at the head of Pennsylvania avenue, at the right of the front entrance to the Treasury Department. In order to locate the station at this point on property belonging to the United States Government, it was necesary to obtain a special act of Congress before the District Commissioners would allow the building to be put up. The illustration shows a very neat shelter. The building is 20 feet in width—the full width of the sidewalk—and 50 feet in length.
